21 **Abstract** Accurate representation of aerosol optical properties is essential for modeling and remote sensing of
22 atmospheric aerosols. Although aerosol optical properties are strongly dependent upon the aerosol size distribution,
23 use of detailed aerosol microphysics schemes in global atmospheric models is inhibited by associated computational
24 demands. Computationally efficient parameterizations for aerosol size are needed. In this study, airborne
25 measurements over the United States (DISCOVER-AQ) and South Korea (KORUS-AQ) are interpreted with a global
26 chemical transport model (GEOS-Chem) to investigate the variation in aerosol size when organic matter (OM) and
27 sulfate-nitrate-ammonium (SNA) are the dominant aerosol components. The airborne measurements exhibit a strong
28 correlation ($r = 0.83$) between dry aerosol size and the sum of OM and SNA mass concentration (M_{SNAOM}). A global
29 microphysical simulation (GEOS-Chem-TOMAS) indicates that M_{SNAOM} , and the ratio between the two components
30 ($\frac{OM}{SNA}$) are the major indicators for SNA and OM dry aerosol size. A parameterization of dry effective radius (R_{eff}) for
31 SNA and OM aerosol is designed to represent the airborne measurements ($R^2 = 0.74$, slope = 1.00) and the GEOS-
32 Chem-TOMAS simulation ($R^2 = 0.72$, slope = 0.81). When applied in the GEOS-Chem high-performance model, this
33 parameterization improves the agreement between the simulated aerosol optical depth (AOD) and the ground-

34 measured AOD from the Aerosol Robotic Network (AERONET; R^2 from 0.68 to 0.73, slope from 0.75 to 0.96). Thus,
35 this parameterization offers a computationally efficient method to represent aerosol size dynamically.

36 1 Introduction

37 Aerosol size has numerous effects on aerosol physical and chemical properties and further on atmospheric chemistry.
38 Aerosol size-dependent heterogeneous chemistry affects gaseous oxidants that in turn affect production rates of
39 aerosol components such as sulfate and secondary organic aerosol (Ervens et al., 2011; Estillore et al., 2016). Aerosol
40 size also affects loss rates due to dry and wet deposition (Seinfeld and Pandis, 2016). Both direct and indirect aerosol
41 radiative forcing are sensitive to aerosol size, as aerosol size affects the interaction between particles and radiation,
42 and the rate at which a particle grows to a cloud droplet (Adams and Seinfeld, 2002; Faxvog and Roessler, 1978;
43 Mishchenko et al., 2002; Emerson et al., 2020). The size dependence of aerosol extinction and scattering phase
44 function also affects the retrieval of aerosol properties from satellites (Levy et al., 2013; Kahn et al., 2005; Jin et al.,
45 2023). Aerosol size affects the fraction of particles that deposit in the body when breathing as well as location within
46 the body where they deposit (Hinds and Zhu, 1999). An appropriate representation of aerosol size is essential for
47 modeling aerosol composition and optical properties (Kodros and Pierce, 2017), interpreting satellite data (Levy et al.,
48 2013; Kahn et al., 2005), studying climate processes (Twomey, 2007; Kellogg, 1980), and moving from aerosol
49 exposure towards dose in health studies (Kodros et al., 2018).

50 The evolution of the aerosol size distribution is affected by various processes, such as nucleation, condensation,
51 coagulation, and deposition. Nucleation events contribute to the number of particles in the nucleation mode (diameters
52 less than about 10 nm) and thus tend to decrease the mean aerosol size for a population (Aalto et al., 2001). In polluted
53 areas with high emission rates of aerosol precursors, mean aerosol size tends to increase by condensation and
54 coagulation (Sakamoto et al., 2016; Sun et al., 2011). Dry and wet aerosol deposition have strong size dependencies
55 due to competing physical processes (Emerson et al., 2020; Ruijrok et al., 1995; Reutter et al., 2009). The aerosol size
56 distribution can be simulated using aerosol microphysical schemes, such as the Two Moment Aerosol Sectional
57 (TOMAS; Adams and Seinfeld, 2002) microphysics model, the Advanced Particle Microphysics (APM; Yu and Luo,
58 2009) model, the Global Model of Aerosol Processes (GLOMAP; Mann et al., 2010), and the Modal Aerosol Module
59 (MAM4; Liu et al., 2016). These schemes have valuable prognostic capabilities; however, their computational cost
60 has limited their use in Chemistry Climate Models (CCMs) or Chemical Transport Models (CTMs). For example, the
61 wall clock time increases by about 2.5 times when APM is enabled in GEOS-Chem CTM relative to the bulk model
62 (GCST et al., 2023). Only 3 of the 10 models that included aerosols, studied by the Atmospheric Chemistry and
63 Climate Model Intercomparison Project, include online size-resolved aerosol microphysics, reflecting its
64 computational cost and complexity (Lamarque et al., 2013; Liu et al., 2012; Szopa et al., 2013; Kodros and Pierce,
65 2017).

66 Methods are needed to better represent aerosol size in CCMs or CTMs without a microphysics scheme (referred to as
67 bulk models). These bulk models usually use prescribed relationships to obtain size-resolved aerosol properties (Croft
68 et al., 2005; Karydis et al., 2011; Zhai et al., 2021), which may insufficiently represent the temporal and spatial

69 variation (Kodros and Pierce, 2017). For example, in the GEOS-Chem CTM, a fixed dry aerosol geometric mean
70 radius (R_g) is assumed for organic matter (OM) and sulfate-nitrate-ammonium (SNA), which is based on analysis of
71 long-term aerosol composition and scattering measurements provided by the IMPROVE network across the
72 continental U.S. (Latimer and Martin, 2019). However, subsequent analysis by Zhai *et al.* (2021) found that this
73 aerosol size underestimated the aerosol mass scattering efficiency and the aerosol extinction coefficients during an
74 aircraft campaign over South Korea (KORUS-AQ). Thus, neglect of aerosol microphysical processes that shape
75 aerosol size distributions can be a significant source of uncertainty in aerosol optical properties in a CTM. A balance
76 between computational cost and representativeness of aerosol size is needed. One option is to use models with size-
77 resolved aerosol microphysics models to inform bulk models, such as was done for the parameterization of biomass
78 burning aerosol size by Sakamoto *et al.* (2016).

79 Recent airborne measurements offer information to evaluate and improve the simulation of aerosol size. DISCOVER-
80 AQ (Deriving Information on Surface Conditions from Column and Vertically Resolved Observations Relevant to Air
81 Quality) was a multi-year campaign over four U.S. cities that provides 3-D resolved measurements of atmospheric
82 gas composition, aerosol composition, size distribution, and optical properties (Choi *et al.*, 2020; Sawamura *et al.*,
83 2017; Chu *et al.*, 2015). KORUS-AQ (the Korea-United States Air Quality Study) offers similar measurements in a
84 different environment with higher aerosol mass loadings (Choi *et al.*, 2020; Zhai *et al.*, 2021; Nault *et al.*, 2018; Jordan
85 *et al.*, 2020).

86 To study the global variation in aerosol size, we explore airborne measurements from DISCOVER-AQ and KORUS-
87 AQ, as well as output from the GEOS-Chem-TOMAS microphysics model. We focus on OM and SNA, which
88 dominate fine aerosol composition in populated areas (Weagle *et al.*, 2018; Geng *et al.*, 2017; Meng *et al.*, 2019; Van
89 Donkelaar *et al.*, 2019; Li *et al.*, 2017). The driving factors for variation in aerosol size are examined. A
90 parameterization of aerosol size using these driving factors is proposed. This parameterization is then applied to a
91 GEOS-Chem high-performance model bulk simulation for global aerosol optical depth (AOD), which is evaluated by
92 ground-measured AOD from the Aerosol Robotic Network (AERONET).

93 **2 Observations and Models**

94 **2.1 Observations**

95 **2.1.1 Aircraft measurements**

96 We examine airborne measurements from two NASA campaigns, DISCOVER-AQ and KORUS-AQ. DISCOVER-
97 AQ includes four deployments in Maryland (MD), California (CA), Texas (TX), and Colorado (CO). KORUS-AQ is
98 an international cooperative field study program conducted in South Korea (KO), sponsored by NASA and the South
99 Korean government through the National Institute of Environmental Research. The year as well as the date and altitude
100 ranges of each deployment are in Table 1.

101

102 **Table 1. Temporal and spatial coverage of each aircraft deployment**

Campaign	Year	Date Range	Altitude from surface
MD	2011	07/01-07/29	0 to 5 km
TX	2013	09/04-09/29	0 to 5 km
CA	2013	01/16-02/06	0 to 4 km
CO	2014	07/17-08/10	0 to 6 km
KO	2016	05/02-06/11	0 to 8 km

103

104 Measurements used in this study include aerosol composition, ambient aerosol extinction, aerosol number size
 105 distribution, gas tracer species, and meteorological data. Measurement methods are listed in Table 2. Measured aerosol
 106 mass is converted from standard to ambient condition before analysis using ambient temperature and pressure. We
 107 use OM directly measured during KORUS-AQ. We use water soluble organic carbon (OC) and a parameterized ratio
 108 between OM and OC (Philip et al., 2014) to calculate OM for DISCOVER-AQ. The parameterized OM is evaluated
 109 with KORUS-AQ data, and overall consistency is found (Figure A1; Appendix A). For both campaigns, dust
 110 concentration is derived from Ca²⁺ and Na⁺ assuming non-sea salt Ca²⁺ accounts for 7.1% of dust mass (Shah et al.,
 111 2020):

$$Dust = \frac{([Ca^{2+}] - 0.0439 \frac{[Na^+]}{2})}{0.071} \quad \text{Eqn. (1)}$$

112 Sea salt is calculated from measured Na⁺ following previous studies (Remoundaki et al., 2013; Malm et al., 1994;
 113 Snider et al., 2016). The crustal component is removed by subtracting 10 % of [Al³⁺] (Remoundaki et al., 2013). A
 114 2.54 scalar is applied to [Na⁺]_{ss} to account for [Cl⁻] (Malm et al., 1994):

$$Sea\ Salt = 2.54([Na^+] - 0.1[Al^{3+}]) \quad \text{Eqn. (2)}$$

115 Effective radius (R_{eff}) (Hansen and Travis, 1974), defined as the area-weighted mean radius of a particle population,
 116 is used as a surrogate for aerosol size:

$$R_{eff} = \frac{\int r \pi r^2 n(r) dr}{\int \pi r^2 n(r) dr} \quad \text{Eqn. (3)}$$

117 Measurement data are screened for dust influence by excluding data with the sum of SNA and OM ($M_{SNAOM} < 4 \times$
 118 dust mass.

119

120 **Table 2. Aircraft observations used in this study***

Variables	DISCOVER-AQ	KORUS-AQ
Bulk aerosol ionic composition	IC-PILS ^a	SAGA ^b
Sub-micron non-refractory aerosol composition	TOC-PILS ^c	HR-ToF-AMS ^d
Refractory black carbon concentration		SP2 ^e
Dry aerosol size distribution	UHSAS ^f or LAS ^g	LAS ^g
Aerosol extinction profile at 532 nm		HSRL ^h
NO ₂	4-Channel Chemiluminescence Instrument ⁱ	
Relative humidity (RH)		DLH ^j

121 * Adapted from Zhai et al. (2021)

122 ^a Ion Chromatography Particle-Into-Liquid Sampler, with a 1.3 μm inlet cutoff aerodynamic diameter (Lee et al., 2003;
123 Hayes et al., 2013).

124 ^b Soluble Acidic Gases and Aerosol (SAGA) instrument (Dibb et al., 2003). The cutoff aerodynamic diameter of the
125 inlet is around 4 μm (McNaughton et al., 2007).

126 ^c Water-soluble organic carbon Particle-Into-Liquid Sampler, with a 1 μm inlet cutoff diameter at 1 atmosphere
127 ambient pressure (Sullivan et al., 2019; Timonen et al., 2010).

128 ^d University of Colorado Boulder High-Resolution Time-of-Flight Aerosol Mass Spectrometer (HR-ToF-AMS) with
129 a 1 μm inlet cutoff diameter (Nault et al., 2018; Guo et al., 2021; Canagaratna et al., 2007).

130 ^e Single-Particle Soot Photometer (SP2), measuring refractory black carbon with a volume equivalent diameter of 100-
131 500 nm (Lamb et al., 2018; Schwarz et al., 2006).

132 ^f Particles with mobility diameters between 60 to 1000 nm can be measured by Ultra-High Sensitivity Aerosol
133 Spectrometer (UHSAS), which illuminates particles with a laser and relate the single-particle light scattering intensity
134 and count rate measured over a wide range of angles to the size-dependent particle concentration (Moore et al., 2021).
135 Particles in the sample are dried to less than 20 % RH.

136 ^g Particles between 100 to 5000 nm measured by Laser Aerosol Spectrometer (LAS, TSI model 3340). The principle
137 of LAS is the same as that of UHSAS, but with a different laser wavelength (1054 nm for the UHSAS and 633 nm for
138 the LAS) and intensity (about 100 times higher for the UHSAS). These differences affect how the instrument sizes
139 non-spherical or absorbing aerosols (Moore et al., 2021). Particles in the sample are dried to less than 20 % RH.

140 ^h NASA Langley airborne High Spectral Resolution Lidar (HSRL) (Hair et al., 2008).

141 ⁱ National Center for Atmospheric Research (NCAR) 4-Channel Chemiluminescence Instrument (Weinheimer et al.,
142 1993)

143 ^j NASA Diode Laser Hygrometer (DLH) (Podolske et al., 2003).

144 **2.1.2 AERONET AOD**

145 We use ground-based AOD observations to evaluate our parameterization and simulated AOD. The Aerosol Robotic
146 Network (AERONET) is a worldwide network that provides long-term sun photometer measured AOD, and is
147 conventionally considered as the ground truth for evaluating model-simulated (Zhai et al., 2021; Meng et al., 2021;
148 Jin et al., 2023) or satellite-retrieved AOD (Levy et al., 2013; Wang et al., 2014a; Kahn et al., 2005; Lyapustin et al.,
149 2018). We use the Version 3 Level 2 database, which includes an improved cloud screening algorithm (Giles et al.,
150 2019). AOD at 550 nm wavelength, interpolated based on the local Ångström exponent at 440 and 670 nm channels,
151 is used in this study. For each site, we use data for the year 2017, excluding months with less than 20 days of
152 measurements and excluding sites with less than 4 months of observations.

153 **2.2 GEOS-Chem simulation**

154 We interpret the aircraft observations with the GEOS-Chem chemical transport model (www.geos-chem.org, last
155 access: 30 October 2022). GEOS-Chem is driven by offline meteorological data from the Goddard Earth Observing
156 System (GEOS) of the NASA Global Modeling and Assimilation Office (Schubert et al., 1993). We use the high-
157 performance implementation of GEOS-Chem (GCHP) (Eastham et al., 2018; Bindle et al., 2021) to examine the
158 effect of variation in aerosol size on AOD. We also use the TOMAS microphysical scheme, coupled with the standard
159 GEOS-Chem implementation (GEOS-Chem Classic), to explicitly resolve aerosol microphysics. The bulk and the
160 microphysics simulations share common emissions and chemical mechanisms. They are both conducted for the year
161 2017 and driven by MERRA-2 meteorological fields.

162 The GEOS-Chem aerosol simulation includes the sulfate-nitrate-ammonium system (Fountoukis and Nenes, 2007;
163 Park, 2004), primary and secondary carbonaceous aerosols (Park et al., 2003; Wang et al., 2014b; Marais et al., 2016;
164 Pye et al., 2010), sea salt (Jaeglé et al., 2011), and mineral dust (Fairlie et al., 2007). The primary emission data are
165 from the Community Emissions Data System (CEDS_{GBD-MAPS}; McDuffie et al., 2020). Dust emission inventories
166 include updated natural dust emission (Meng et al., 2021b), and anthropogenic fugitive, combustion, and industrial
167 dust (AFCID; Philip et al., 2017). Resolution-dependent soil NO_x, sea salt, biogenic VOC, and natural dust emissions
168 are calculated offline at native meteorological resolution to produce consistent emissions across resolution (Weng et
169 al., 2020; Meng et al., 2021b). Biomass burning emissions use the Global Fire Emissions Database, version 4 (GFED4)
170 (Van Der Werf et al., 2017). We estimate organic matter (OM) from primary organic carbon using the same OM/OC
171 parameterizations as applied for DISCOVER-AQ (Philip et al., 2014; Canagaratna et al., 2015). Dry and wet
172 deposition follows Amos *et al.* (2012), with a standard resistance-in-series dry deposition scheme (Wang et al., 1998).
173 Wet deposition includes scavenging processes from convection and large-scale precipitation (Liu et al., 2001).

174 Global relative humidity dependent aerosol optical properties are based on the Global Aerosol Data Set (GADS)
175 (Kopke P., 1997; Martin et al., 2003) with updates for SNA and OM (Latimer and Martin, 2019), mineral dust (Zhang
176 et al., 2013), and absorbing brown carbon (Hammer et al., 2016). In the current GEOS-Chem model, the SNA and

177 OM R_{eff} of particular interest here are based on co-located measurements of aerosol scatter and mass from the
178 IMPROVE network at U.S. national parks over the period 2000-2010, together with a κ -Kohler framework for aerosol
179 hygroscopicity (Kreidenweis et al., 2008) as implemented by Latimer and Martin (2019). Aerosol extinction is
180 calculated as the sum of extinction from each aerosol component with aerosol optical properties listed in Table A1, as
181 described in Appendix A2.

182 A global GCHP simulation (Eastham et al., 2018) version 13.0.0 (DOI: 10.5281/zenodo.4618180) that includes
183 advances in performance and usability (Martin et al., 2022), is conducted on a C90 cubed-sphere grid corresponding
184 to a horizontal resolution of about 100 km, with a spin-up time of 1 month.

185 The TOMAS microphysics scheme, coupled with the GEOS-Chem simulation, conserves aerosol mass, and tracks
186 particles with diameters from approximately 1 nm to 10 μm (Adams and Seinfeld, 2002). Microphysical processes in
187 TOMAS include nucleation, condensation, evaporation, coagulation, and wet and dry deposition (Adams and Seinfeld,
188 2002). Nucleation in TOMAS follows a ternary scheme (sulfuric acid, ammonia, and water) when ammonia mixing
189 ratios are greater than 0.1 ppt; otherwise, a binary nucleation scheme is used (Napari et al., 2002). The nucleation rate
190 is scaled by 10^{-5} to better match the observations (Westervelt et al., 2013). The condensation and evaporation algorithm
191 is based on a study from Tzivion *et al.* (1989), including interaction with secondary organic aerosol (D'Andrea et al.,
192 2013). Interstitial coagulation in clouds is also included (Pierce et al., 2015).

193 For each size bin, TOMAS tracks the mass and number of sulfate, sea salt, black carbon, OC, dust, and water. Primary
194 sulfate emissions have 2 lognormal modes: 15% of the mass with a number median diameter (NMD) of 10 nm and
195 geometric standard deviation (σ) of 1.6 and the remainder with a NMD of 70 nm and σ of 2 (Adams and Seinfeld,
196 2003). The size of emitted carbonaceous particles varies depending on the source: those produced by fossil fuel have
197 a NMD of 30 nm and σ of 2, while biofuel and biomass burning particles are emitted with a NMD of 100 nm and σ
198 of 2 (Pierce et al., 2007). Meteorology and most of the emissions in GEOS-Chem-TOMAS follow the bulk simulation,
199 except that online schemes are used for dust (Zender et al., 2003) and sea salt (Jaeglé *et al.* 2011).

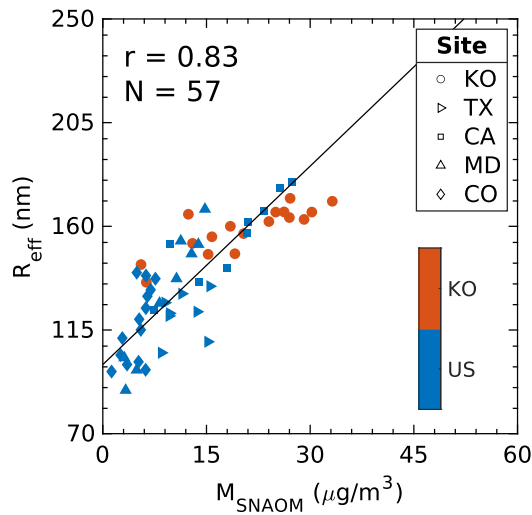

200 The GEOS-Chem-TOMAS (version 13.2.1. DOI: 10.5281/zenodo.5500717) is used to provide insights into global
201 scale aerosol size variation and the driving factors. For computational feasibility, a one-year global simulation is
202 conducted with a horizontal resolution of $4^\circ \times 5^\circ$ and 47 vertical layers from surface to 0.01 hPa. The spin-up time is
203 1 month. Aerosols are tracked in 15 size bins with particle diameters ranging from about 3 nm to 10 μm . We also
204 conducted a $2^\circ \times 2.5^\circ$ simulation for October to evaluate the sensitivity of our conclusions to the resolution of the
205 aerosol microphysics simulation.

206 **3 Development of a Parameterization of Aerosol Size**

207 We first examine the aircraft measurements for insight into the observed variation in aerosol size. Then we apply the
208 size-resolved GEOS-Chem-TOMAS model to extend our analysis to the global scale and identify driving factors of
209 aerosol size. We subsequently develop and test a parameterization of aerosol size for use in bulk models.

210 **3.1 Observed variation in aerosol size**

211 Figure 1 shows the daily-mean dry effective radius from DISCOVER-AQ and KORUS-AQ as a function of aerosol
212 mass. Aerosol size, in terms of dry R_{eff} , ranges from 90 nm to 179 nm for DISCOVER-AQ, which is generally smaller
213 than for KORUS-AQ that ranges from 135 nm to 174 nm. M_{SNAOM} from DISCOVER-AQ ($1.4 \mu\text{g}/\text{m}^3$ to $27.4 \mu\text{g}/\text{m}^3$)
214 is also generally less than that from KORUS-AQ ($5.5 \mu\text{g}/\text{m}^3$ to $33.2 \mu\text{g}/\text{m}^3$). A strong correlation ($r = 0.83$) between
215 aerosol size and M_{SNAOM} is evident. R_{eff} from KORUS-AQ is less sensitive to M_{SNAOM} (slope = 1.23) compared to
216 DISCOVER-AQ (slope = 3.57). The relatively large particle size at low mass concentration during KORUS-AQ might
217 reflect the influence of aged aerosol transported from upwind (Jordan et al., 2020; Zhai et al., 2021; Nault et al., 2018).

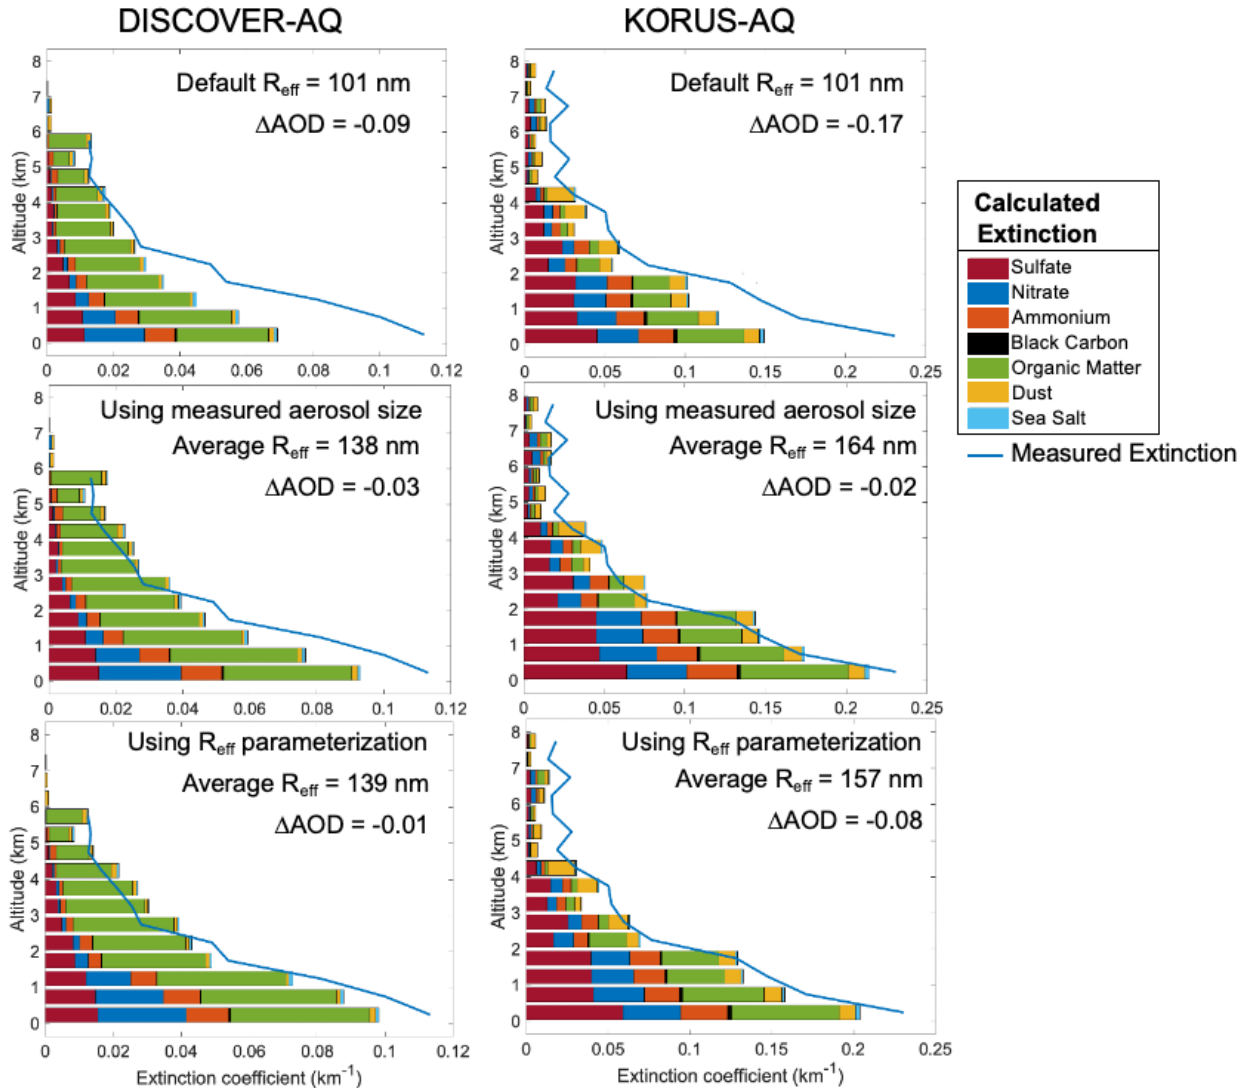

218

219 **Figure 1. Airborne measurements of dry effective radius (R_{eff}) versus the sum of SNA and OM mass**
220 **(M_{SNAOM}) for DISCOVER-AQ (Maryland is abbreviated as MD, California as CA, Texas as TX, Colorado as**
221 **CO) and for KORUS-AQ (KO) campaigns. Each point represents a daily average for the entire flight profile.**
222 **Only data with $M_{\text{SNAOM}} > 4 \times \text{Dust mass}$ is used.**

223 The positive relationship between dry aerosol size and mass of SNA and OM reflects the roles of emission,
224 condensation, and coagulation in simultaneously increasing aerosol size and mass. This general tendency is also
225 observed by many other studies (e.g., Sakamoto et al., 2016; Rodríguez et al., 2007; Sun et al., 2012; Bahreini et al.,
226 2003) despite variable aerosol sources and growth mechanisms. In cities, the joint increases in aerosol size and mass
227 are usually attributable to anthropogenic emissions and condensation (Tian et al., 2019; Sun et al., 2011; Huang et al.,
228 2013). In remote areas, biomass burning shifts the particle size distribution toward larger radii due to high emission
229 rates and coagulation in plumes (Rissler et al., 2006; Ramnarine et al., 2019) that, for example, increase both aerosol
230 size and mass from the wet season to the dry season in Amazonia (Rissler et al., 2006; Andreae et al., 2015). The
231 positive relationship between aerosol size and mass suggests the possibility of using aerosol mass as a predictor of
232 R_{eff} .

233 We examine the ability of the GEOS-Chem bulk model to reproduce the observed extinction. The top panel of Figure
234 2 compares the measured aerosol extinction profiles to calculated aerosol extinction profiles using default R_{eff} . Details
235 about the calculation are described in Appendix A2. Both measured and calculated extinction profiles exhibit
236 increasing extinction toward the surface associated with increasing aerosol mass concentrations. However, biases are
237 apparent for both DISCOVER-AQ and KORUS-AQ. The R_{eff} from KORUS-AQ shown in Figure 1 have a mean value
238 of 164 nm, larger than the value of 101 nm inferred by Latimer & Martin (2019) based on measurements of aerosol
239 scatter and mass by the U.S. IMPROVE network. This bias was previously noted by Zhai *et al.* (2021). The mean R_{eff}
240 from DISCOVER-AQ of 138 nm is also larger than the inferred value. This likely reflects representativeness
241 differences since the DISCOVER-AQ deployments focused on major urban areas during months of high aerosol
242 loadings, while the IMPROVE measurements were at national parks throughout the year. The middle panel shows the
243 calculated extinction using the measured aerosol size distribution. Applying the measured aerosol size distribution
244 addresses most discrepancies between the calculated and measured aerosol extinction profile for both KORUS-AQ
245 and DISCOVER-AQ. The corresponding discrepancies in AOD estimation also significantly decreased (from 0.09 to
246 0.03 for DISCOVER-AQ and from 0.17 to 0.02 for KORUS-AQ). The reduced discrepancies support the conclusions
247 from Zhai *et al.* (2021) that the GEOS-Chem aerosol size is underestimated for KORUS-AQ and motivate
248 parameterization of R_{eff} for efficient representation of aerosol size for global scale aerosol modeling.

249
 250 **Figure 2. Aerosol extinction profile for the DISCOVER-AQ and KORUS-AQ aircraft campaigns. Blue lines**
 251 **are the measured extinction profiles. Horizontal bars are calculated extinction using (top) default GEOS-**
 252 **Chem R_{eff} , (middle) measured R_{eff} , and (bottom) parameterized R_{eff} (described in Section 3.3), together with**
 253 **measured aerosol composition and RH. The aerosol extinction calculation is described in Appendix A.**

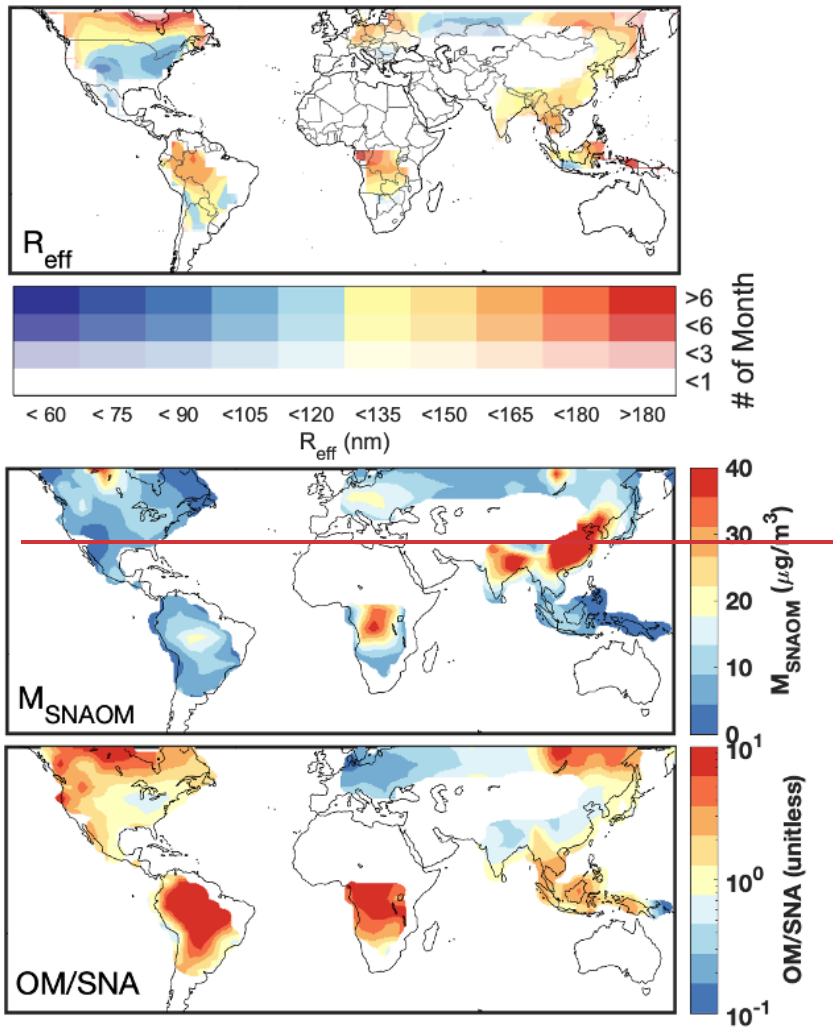

254 **3.2 Driving factors**

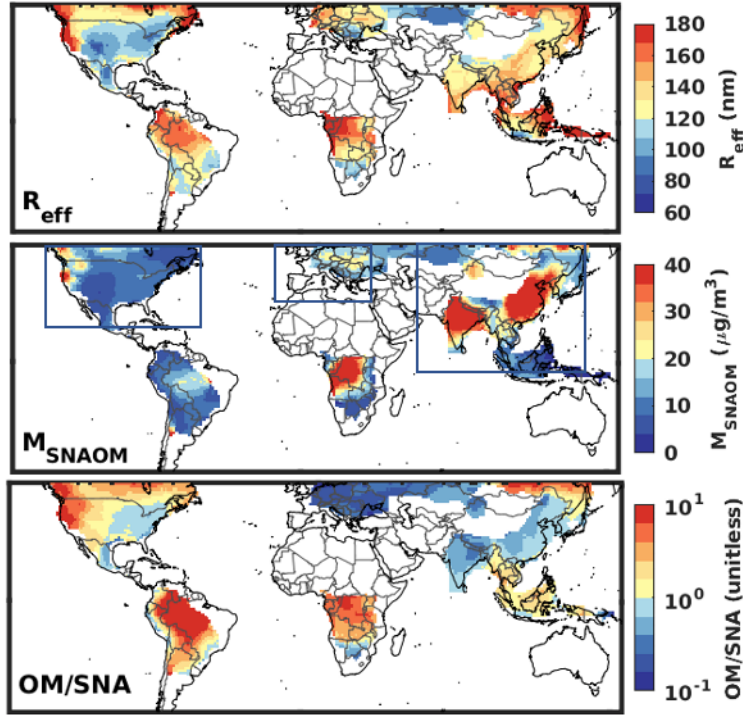

255 Given the strong positive correlation of aerosol mass with aerosol size, we further examine this relationship globally
 256 using GEOS-Chem coupled with the TOMAS aerosol microphysics scheme. To focus on areas that are dominated by
 257 SNA and OM, we only include grid boxes with $M_{\text{SNAOM}} > 90\%$ of the aerosol mass. Inspection of the GEOS-Chem-
 258 TOMAS size distribution across continental regimes reveals a general tendency for the distribution to shift toward
 259 smaller sizes as R_{eff} decreases and toward larger sizes as R_{eff} increases, thus supporting the use of the single summary
 260 statistic of R_{eff} for aerosol size. The top panel of Figure 3 shows the geographic distribution of annual mean surface
 261 layer R_{eff} for locations and months grid boxes that meet the criterion where aerosol mass is dominated by SNA and

262 ~~OM, as indicated by $M_{\text{SNAOM}} > 90\%$ of the aerosol mass.~~ Among the areas of interest, biomass burning regions of
263 Central Africa, South America, and boreal forests of North America exhibit the highest surface R_{eff} of about 180 nm.
264 Industrial areas such as East Asia and South Asia also exhibit high R_{eff} of about 130 nm, given an abundance of particle
265 emissions and gaseous precursors. The lowest surface R_{eff} of about 80 nm is found in North America, where aerosol
266 mass concentrations are low.

267 The middle panel of Figure 3 shows the simulated M_{SNAOM} from GEOS-Chem-TOMAS. Enhanced M_{SNAOM}
268 concentrations of over $40 \mu\text{g}/\text{m}^3$ are apparent over East Asia and South Asia, reflecting intense anthropogenic
269 emissions. Another M_{SNAOM} hotspot can be seen in Central Africa, driven by biomass burning during the dry season
270 (Van Der Werf et al., 2017; McDuffie et al., 2021) and sometimes exacerbated by anthropogenic emissions (Ngo et
271 al., 2019). Moving from North America to Europe, and then to Asia (defined by boxes in the middle panel), M_{SNAOM}
272 concentrations exhibit a generally increasing tendency (mean value of 11, 17, and $25 \mu\text{g}/\text{m}^3$, respectively), consistent
273 with the R_{eff} tendency (mean value of 124, 133, and 136 nm, respectively) in the top panel and aligning with the
274 relationship between aircraft measurements over the U.S. and South Korea.

275 However, in South America, where R_{eff} is among the highest, M_{SNAOM} is relatively low. This discrepancy motivates
276 the search for other factors, such as aerosol composition, that are associated with aerosol size. In South America,
277 aerosol mass is mostly from natural sources, particularly biomass burning during the dry seasons. R_g for a particle
278 population from biomass burning ranges from 60 nm to 170 nm (Rissler et al., 2006; Reid et al., 2005; Janháall et al.,
279 2010), usually larger than that of primary sulfate aerosol (5 to 35 nm) (Whitey, 1978; Plaza et al., 2011). Therefore,
280 the relative abundance of OM in the total M_{SNAOM} can serve as another predictor of R_{eff} . The bottom panel of Figure
281 3 shows the ratio between OM and SNA mass. In addition to the Amazon basin, the biomass burning regions of Central
282 Africa and boreal forests in Asia and North America are all areas with high OM mass fractions, which contribute to
283 their high R_{eff} .

285

286 **Figure 3: Geographic distribution of GEOS-Chem-TOMAS-simulated annual mean surface layer aerosol**
 287 **properties; (top) R_{eff} when $M_{SNAOM} > 90\%$ of aerosol mass, (middle) the sum of SNA and OM mass (M_{SNAOM}),**
 288 **and (bottom) OM/SNA.**

289 3.3 Parameterization and evaluation

290 We use Multiple Linear Regression (MLR) to derive a parameterization of dry R_{eff} for SNA and OM as a function of
 291 M_{SNAOM} and OM/SNA. We sample the GEOS-Chem-TOMAS simulation for locations dominated by M_{SNAOM} ($> 90\%$).
 292 We include all qualified data (8,569 grid boxes) from the planetary boundary layer (PBL) to focus on this region,
 293 while randomly sample 0.5% of simulations in the free troposphere (217,772 grid boxes) to allow the influence of
 294 remote regions in the training set. The reason for focusing on the PBL is twofold. First, the PBL generally has the
 295 highest aerosol loading that largely determines the columnar mass and AOD (Koffi et al., 2016; Zhai et al., 2021; Tian
 296 et al., 2019). Second, the PBL is the domain where most model-measurement difference exists (Figure 2, top panel).

297 Taking the logarithm of R_{eff} and the logarithm of the two predictors facilitates linear relationships for regression,
 298 which yields the initial parameterization

$$R_{eff} = 78.3 M_{SNAOM}^{0.20} \left(\frac{OM}{SNA} \right)^{0.065} \quad \text{Eqn. (4)}$$

299 where R_{eff} has units of nm, M_{SNAOM} has units of $\mu\text{g}/\text{m}^3$, and OM/SNA is unitless. The R_{eff} parameterization is driven
 300 primarily by the mass of SNA and OM, modulated by the ratio of OM to SNA. This equation well represents the
 301 variation of R_{eff} during the aircraft campaigns with an R^2 of 0.74 (Figure B1, top left). The slope below unity (0.90)

302 likely reflects the effect of coarse model resolution, which dilutes the particle or precursor concentration in turn
303 reducing condensation and coagulation growth (AboEl-Fetouh et al., 2022; Ramnarine et al., 2019; Sakamoto et al.,
304 2016). Adjustment to this parameterization to account for these effects and align the slope with the airborne
305 measurements rather than the model results in a final parameterization of

$$R_{eff} = 87.0 M_{SNAOM}^{0.20} \left(\frac{OM}{SNA} \right)^{0.065} \quad \text{Eqn. (5)}$$

306 Figure 4 shows the distribution of dry R_{eff} based on GEOS-Chem-TOMAS and Eqn. (5). Circles in Figure 4 show the
307 mean values of the sampled GEOS-Chem-TOMAS simulated R_{eff} as a function of simulated M_{SNAOM} concentrations,
308 ranging from 0.02 to 102 $\mu\text{g}/\text{m}^3$, and OM/SNA ranging from 0.13 to 55. Simulated R_{eff} extends from 15 nm when both
309 M_{SNAOM} and OM/SNA are low (0.09 $\mu\text{g}/\text{m}^3$ and 1.3, respectively), up to 282 nm when M_{SNAOM} and OM/SNA are high
310 (about 44 $\mu\text{g}/\text{m}^3$ and 14 respectively). The background color indicates our parameterized R_{eff} . A high degree of
311 consistency exists between the parameterized R_{eff} and simulated R_{eff} , especially in the free troposphere where large
312 gradients in R_{eff} exist, with overall for the troposphere an R^2 of 0.72, and a slope of 0.81 (Figure B1, bottom right). At
313 the lower end of R_{eff} , the agreement between simulation and the parameterization can also be found in Figure B1,
314 which shows that the small R_{eff} are reproduced by the parameterization. Despite the overall consistency, a few
315 differences exist. When aerosol mass concentration is high, the parameterization tends to yield a higher R_{eff} than in
316 the GEOS-Chem-TOMAS simulation, since the adjustment using aircraft measurements led to 11% increase in R_{eff} .
317 At M_{SNAOM} near 10 $\mu\text{g}/\text{m}^3$ and OM/SNA near 10, the simulation indicates higher R_{eff} than the parameterization,
318 reflecting dilution downwind of biomass burning that reduces the aerosol mass concentration but has less influence
319 on particle size in GEOS-Chem-TOMAS (Park et al., 2013; Rissler et al., 2006; Sakamoto et al., 2016). A 10-20%
320 underestimation in the parameterization at low OM/SNA reflects the advection and dilution ~~of~~ downwind of urban
321 areas and in the free troposphere (Yue et al., 2010; Asmi et al., 2011). Evaluation of our parameterization versus the
322 GEOS-Chem-TOMAS simulation of $2^\circ \times 2.5^\circ$ for October yields similar results but explains an additional 14% of the
323 variance in simulated R_{eff} , providing additional evidence of the fidelity of the parameterization.

324

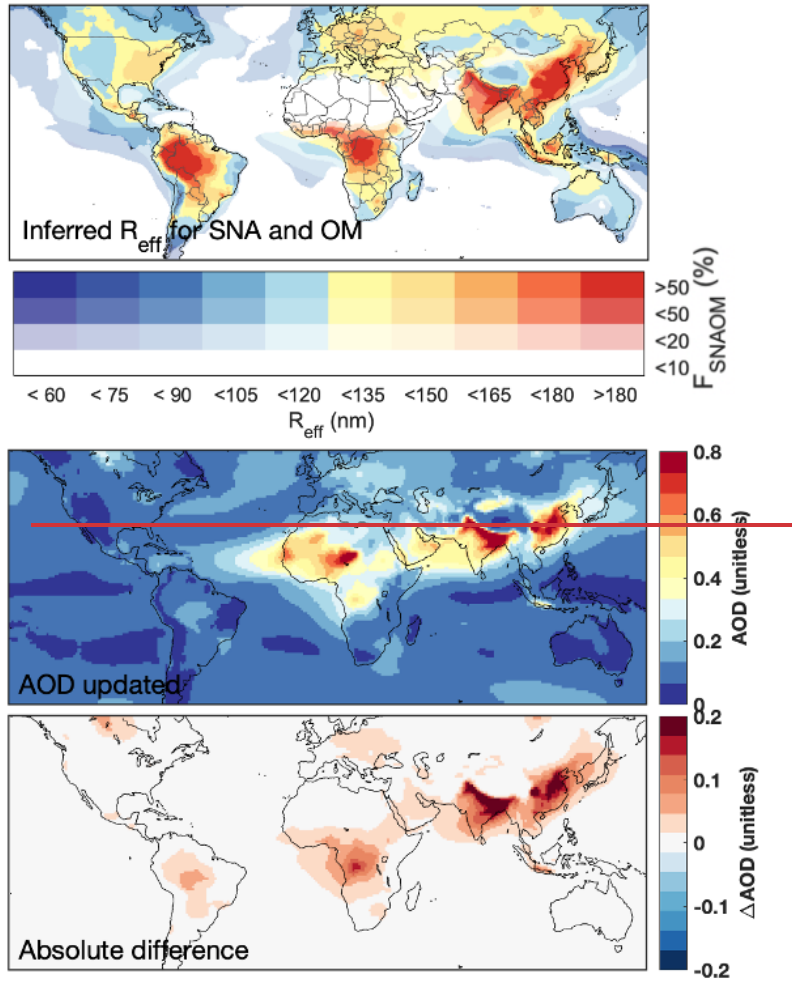

325 **Figure 4. Dry R_{eff} as a function of M_{SNAOM} and OM/SNA when SNA and OM are dominant (>90%). Each**
 326 **circle represents the mean value of the GEOS-Chem-TOMAS simulated R_{eff} in each bin. Background color**
 327 **indicates the parameterized R_{eff} .**

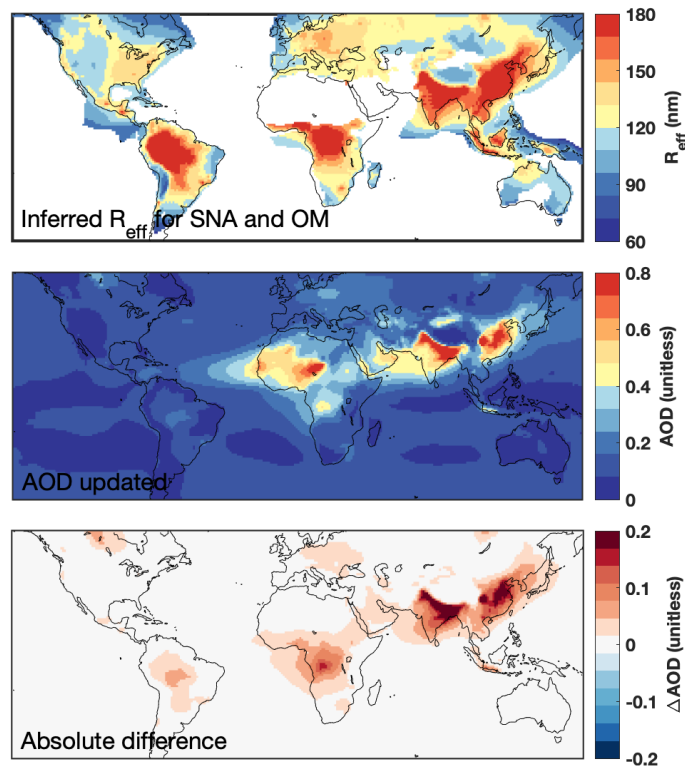

328 When applied to the airborne measurements, this parameterization only slightly overestimates the measured R_{eff} from
 329 DISCOVER-AQ (139 nm vs. 138 nm) and slightly underestimates R_{eff} from KORUS-AQ (157 nm vs. 164 nm).
 330 Discrepancies between calculated and measured extinction from aircraft campaigns are largely reduced (Figure 2,
 331 bottom panel) with AOD biases of 0.01 and 0.08 for DISCOVER-AQ and KORUS-AQ, respectively. Minor
 332 differences are still present in aerosol extinction above 4 km for KORUS-AQ, but a physical explanation remains
 333 elusive since the calculated extinction is biased even if measured aerosol size and composition are used; instrument
 334 uncertainties may play a role. Nonetheless, effects on columnar AOD from these disagreements aloft are minor (<5%).

335 We then apply Eqn. (5) to a GEOS-Chem bulk simulation to calculate R_{eff} and AOD. The top panel of Figure 5 shows
 336 the annual mean dry R_{eff} for surface SNA and OM aerosol. The parameterized R_{eff} is usually higher than the default
 337 value of about 100 nm in GEOS-Chem over land, and lower than that over the ocean, with a normalized root mean
 338 square deviation (NRMSD) of 43.8%. The parameterized spatial pattern well represents the GEOS-Chem TOMAS
 339 simulation, with high R_{eff} found is the highest in biomass burning regions in South America and Central Africa, as
 340 well as industrial regions in Asia, similar to the pattern found in the GEOS-Chem-TOMAS simulation. The
 341 parameterized R_{eff} and its horizontal variation diminishes with altitude (Figure B2), with the mean R_{eff} decreasing
 342 from of 85 nm at the surface decreasing by 18.8% to 69 nm at about 5 km 85 nm (surface) to 43 nm (10 km). By design,
 343 the parameterization has little effect in regions and seasons where and when M_{SNAOM} is not dominant, since the
 344 parameterization only affects R_{eff} of SNA and OM.

345 The middle panel of Figure 5 shows the simulated AOD, with the corresponding difference between the base
 346 simulation and the updated simulation in the bottom panel. To accommodate the parameterized R_{eff} , a look-up table

347 with a wide range of R_{eff} (0.02 μm to 1.7 μm) and the corresponding extinction efficiencies for OM and SNA is created
348 based on Mie Theory (Mishchenko et al., 2002, 1999). This update generally increases aerosol mass scattering by
349 increasing the mass extinction efficiency, in turn, increasing AOD over regions with strong anthropogenic sources,
350 such as East Asia (by 0.10, 28.3%) and South Asia (by 0.14, 31.1%). It also slightly increases AOD over regions
351 influenced by wildfires, such as South America (by 0.02, 19.7%), Central Africa (by 0.03, 22.7%), and the boreal
352 forests in Europe (by 0.01, 9.9%). Most increases occur near the surface (Figure B3), where the highest aerosol mass
353 loading and mass extinction efficiency exist. The NRMSD between original and updated GEOS-Chem simulated AOD
354 is 18.9% globally, and 25.6% over continents.

356

357 **Figure 5. (Top) Surface dry R_{eff} for SNA and OM calculated using Eqn. (5) and GEOS-Chem bulk model**
 358 **simulated SNA and OM mass. F_{SNAOM} is the ratio of SNA and OM mass to the total aerosol mass at the**
 359 **surface R_{eff} is shown when M_{SNAOM} is greater than 80% of the total aerosol mass. (Middle) The GEOS-Chem**
 360 **simulated AOD using inferred R_{eff} . (Bottom) the absolute difference between updated AOD and default AOD**
 361 **using dry $R_{eff} = 101$ nm.**

362 Although R_{eff} is only one of many processes affecting AOD, we evaluate the effect of the parameterization on the
 363 GEOS-Chem simulation of AOD to assess its implications. The left and middle panels of Figure 6 shows for the
 364 default R_{eff} , the percent difference discrepancy between GEOS-Chem simulated AOD and AERONET AOD as a
 365 function of the parameterized surface R_{eff} for SNA and OM. The simulation using the default R_{eff} (Figure 6, left panel)
 366 slightly overestimates AOD at sites with small parameterized R_{eff} and underestimates AOD at sites with large
 367 parameterized R_{eff} . The overestimates occur primarily in western Europe where SNA and OM concentrations are low,
 368 while the underestimates happen mainly over industrial regions in East Asia, Southeast Asia, and biomass burning
 369 areas in South America and Central Africa, where the SNA and OM mass loading are high (Figure B4). The
 370 underestimates are mitigated when applying the parameterized R_{eff} in GEOS-Chem (Figure 6, middle panel), yielding
 371 increased consistency between the measured (AERONET) AOD and simulated AOD (Figure 6, right; R^2 change from
 372 0.68 to 0.74, slope from 0.75 to 0.94).

373

374 **Figure 6. (Left and middle) Percent increase in GEOS-Chem simulated AOD minus AERONET AOD as a**

 376 **in each 35 nm bin; error bars represent the corresponding standard deviation. (Right) Scatter plot of**
 377 **AERONET versus simulated AOD with the default R_{eff} (blue dots, line, and text), and with the parameterized**
 378 **R_{eff} (red dots, line, and text). The 1:1 line is dashed. NRMSD is the normalized root mean square deviation**
 379 **between the two datasets. N is the number of points in each dataset.**

380 4 Conclusion

381 Aerosol size strongly determines mass scattering efficiency with implications for calculation of aerosol optical
 382 properties. Prior work found that the global mean dry aerosol size used in a bulk aerosol model induced low bias
 383 versus measured extinction in a region with a high aerosol loading (Zhai et al., 2021). We interpreted aircraft
 384 measurements from DISCOVER-AQ and KORUS-AQ with a chemical transport model (GEOS-Chem) to better
 385 understand regional variation in aerosol size. The measurements had a strong positive correlation ($r = 0.83$) between
 386 aerosol size and mass of sulfate-nitrate-ammonium (SNA) and organic matter (OM), reflecting the high condensation
 387 and coagulation rates where emissions of particles and the gaseous precursors are abundant, indicating the possibility
 388 of using aerosol mass as a predictor of aerosol size.

389 To gain a broader perspective of the global variation in aerosol size, we used the TOMAS microphysics package of
 390 the GEOS-Chem model to simulate the monthly mean aerosol mass, composition, and size distribution. We used
 391 effective radius (R_{eff}) as a surrogate of aerosol size and examined its relationship with aerosol mass and components
 392 where SNA and OM were dominant. We found that the sum of SNA and OM concentration, and the ratio between
 393 them, were the major predictors of R_{eff} . We used GEOS-Chem-TOMAS model output to derive a parameterization of
 394 R_{eff} , which well reproduced R_{eff} measured from the aircraft campaigns ($R^2 = 0.74$). When applied in the bulk GEOS-
 395 Chem high-performance model, the parameterization tended to increase R_{eff} of SNA and OM over regions with high
 396 concentrations of SNA and OM, and decrease R_{eff} elsewhere relative to the standard model. This led to a global
 397 normalized root mean square deviation (NRMSD) of 43.8% between the original and updated surface R_{eff} . The
 398 parameterized R_{eff} tended to increase the vertical gradient in extinction relative to the standard model, due to the
 399 decrease in R_{eff} with altitude. The NRMSD of global mean AOD between the original and updated simulations was

400 18.9%, with the most significant regional AOD increase of 0.14 in South Asia, where aerosol mass loadings are high.
401 This parameterization led to improved consistency of GEOS-Chem simulated AOD with AERONET AOD (R^2 from
402 0.68 to 0.74; slope from 0.75 to 0.94), by increasing AOD at high R_{eff} .

403 Overall, the simple parameterization of R_{eff} derived in this study improved the accuracy in modeling aerosol optical
404 properties without imposing additional computational expense. Other chemical transport models and modeling of
405 other size-related processes, such as heterogeneous chemistry, photolysis frequencies, and dry deposition, may also
406 benefit from the parameterized R_{eff} . Future work could include additional parameters to better summarize the aerosol
407 size distribution. Further developments in computational efficiency of aerosol microphysics models and more
408 abundant measurements of aerosol size and optical properties would both offer opportunities for further advances.

409

410 *Data availability.* AERONET data can be found at <https://aeronet.gsfc.nasa.gov/>. Aircraft data during DISCOVER-
411 AQ are available at <https://asdc.larc.nasa.gov/project/DISCOVER-AQ>. KORUS-AQ data can be found at
412 <https://doi.org/10.5067/Suborbital/KORUSAQ/DATA01>.

413 *Author contributions.* HZ and RVM designed the study. HZ performed the data analysis and model simulations with
414 contributions from BC, SZ, CL, LB, JRP, IS, DC, and RYWC. BEA, LDZ, JWH, RAF, CAH, JLJ, PCJ, JED, JSS,
415 AW, and BAN contributed to KORUS-AQ and DISCOVER-AQ campaign measurements. HZ and RVM wrote the
416 paper with input from all authors.

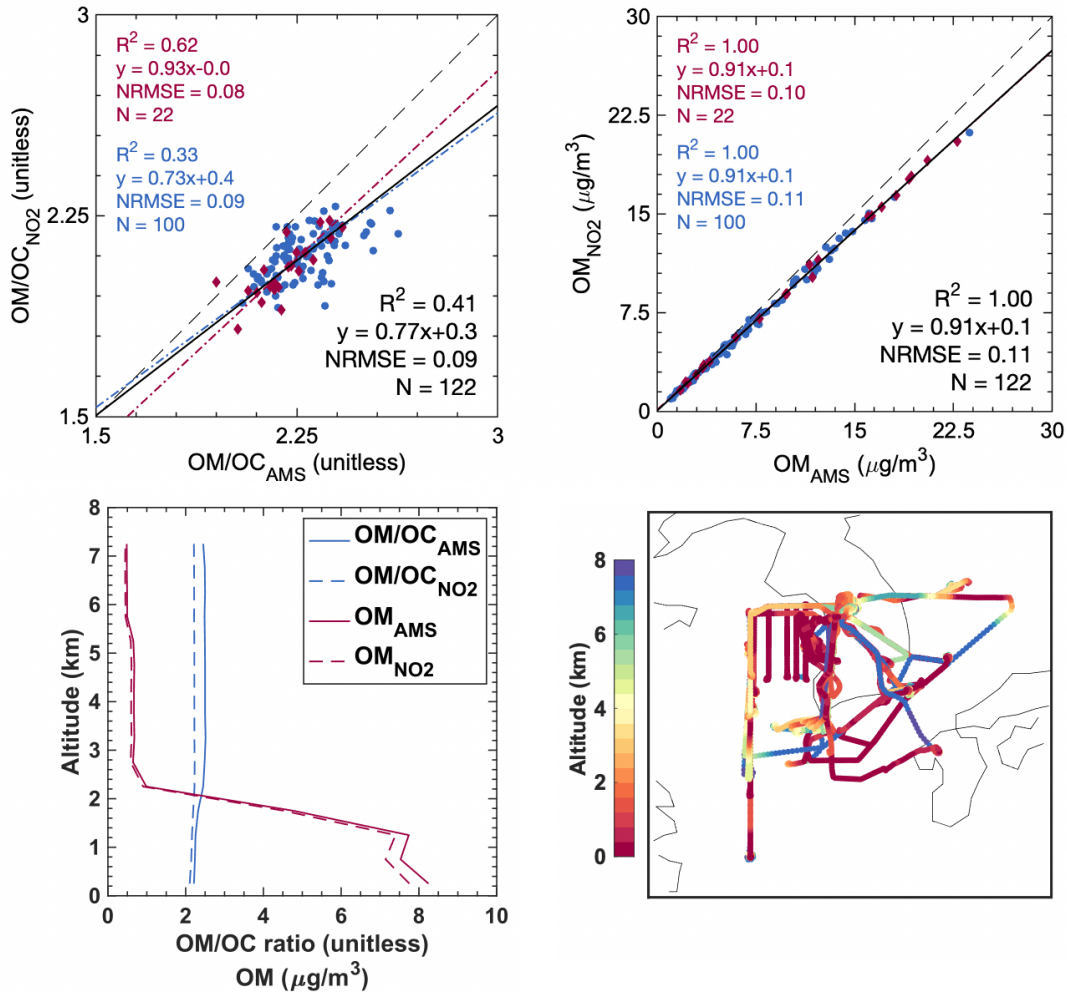

417 *Competing interests.* The contact author has declared that neither they nor their co-authors have any competing
418 interests.

419 *Financial support.* This work was supported by NASA Grant 80NSSC21K1343. JRP was funded by the US NSF
420 Atmospheric Chemistry program, under grant AGS-1950327. JLJ and PCJ were supported by NASA Grant
421 80NSSC21K1451 and NNX15AT96G. BAN was supported by NASA Grant 80NSSC22K0283. JED was supported
422 by NASA Grant NNX15AT88G.

423 **Appendix A**

424 **A1 Application of spatially and temporally varying OM/OC ratio**

425 The top panel of Figure A1 shows scatter plots of the estimated and measured OM/OC and OM during the KORUS-
 426 AQ campaign. The estimation is obtained by applying to OC measurement a NO₂ inferred OM/OC from (Philip *et al.*,
 427 2014), with a subsequent correction factor of 1.09 suggested by Canagaratna *et al.* (2015). Estimated OM is compared
 428 with measured OM by AMS during the campaign. Overall consistency is evident between NO₂-derived OM/OC and
 429 measured OM/OC. The agreement is better below 500 m than above (left panel, R² = 0.62 vs. 0.33). The discrepancy
 430 at high altitudes is mainly due to the low NO₂ (<0.2 ppbv), where the Philip *et al.* (2014) equation is not applicable.
 431 An average OM/OC ratio (2.1) is applied in this case. A high degree of consistency exists between the estimated OM
 432 and measured OM, with R² = 0.99 and slope = 0.91 for data from all altitudes (right panel), thus supporting the use of
 433 estimated OM in our analyses. The bottom left panel compares the vertical profile of the estimates and measurements,
 434 yielding overall consistency.

435

436 **Figure A1. Scatter plots of estimated and measured OM/OC (top left) and OM (top right) during KORUS-**
437 **AQ. Each point represents a mean value of AMS measurement for a 1-hour interval. Red diamonds, lines,**
438 **and texts represent data from 0-500 m altitude. Blue dots, lines, and text represent data above 500 m from the**
439 **ground. Black solid lines and texts represent the line of best fit for all the data. The 1:1 line is dashed.**

441 **each dataset. (Bottom left) Mean values of OM/OC and OM from measurements and estimations along the**
442 **altitude. (Bottom right) Flight tracks during KORUS-AQ.**

443

444 **A2 Aerosol Extinction Calculation in GEOS-Chem**

445 Extinction (Ext) of radiation by aerosols is represented as the sum of extinction due to each of the aerosol components
 446 using the following equation:

$$Ext_k = \frac{3Q_{ext,k}M_k}{4\rho_kR_{eff,k}} \quad \text{Eqn. (3)}$$

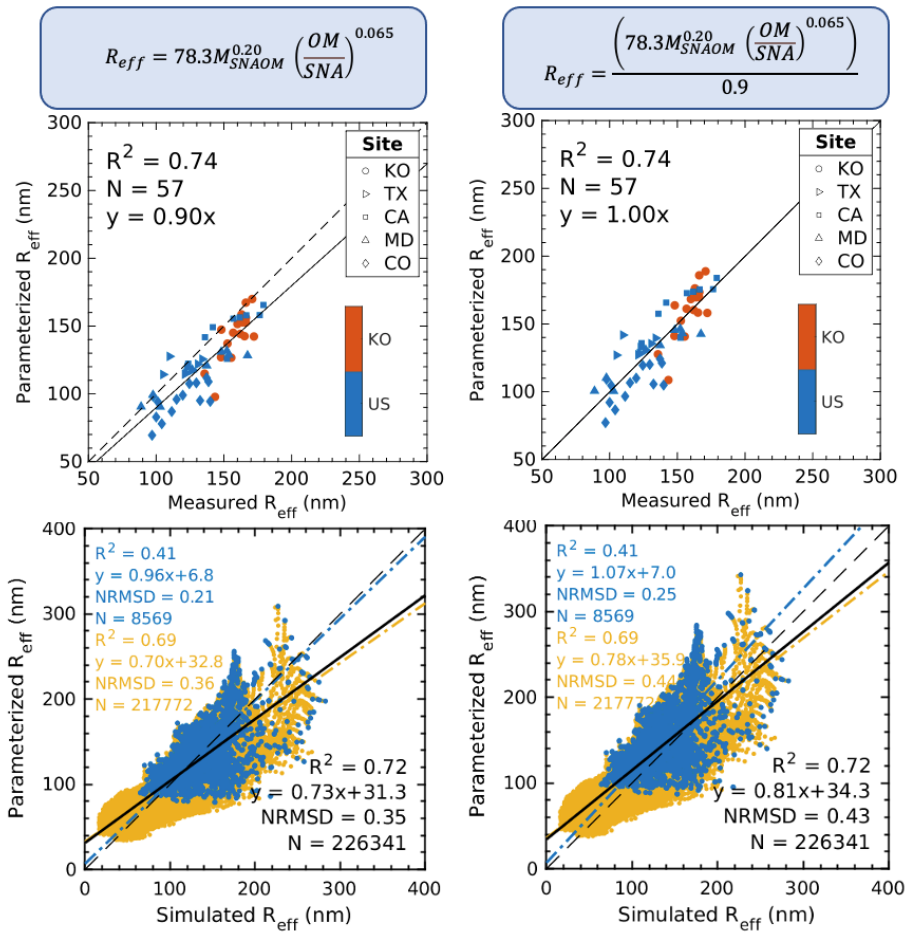

447 where subscript k indicates the property for the kth component. R_{eff} is the effective radius defined as the area weighted
 448 mean radius. Q_{ext} is the area-weighted mean extinction efficiency. M is the aerosol mass loading per unit volume. ρ is
 449 the aerosol density. Aerosol optical depth (AOD) is the integral of aerosol extinction across the vertical domain.

450 For each component, extinction is calculated for assumed log-normal size distribution with corresponding dry
 451 geometric mean radius R_g and geometric standard deviation σ, hygroscopicity, refractive index (RI), and density (ρ)
 452 for individual aerosol components, as listed in Table A1. Sulfate, nitrate, and ammonium are grouped into SNA for
 453 convenience. R_{eff} and Q_{ext} are calculated using Mie Theory (Mishchenko et al., 1999, 2002) based on assumptions in
 454 aerosol size and RI. Hygroscopicity for SNA and OM is represented using a κ-Kohler hygroscopic growth scheme
 455 (Kreidenweis et al., 2008) as implemented by (Latimer and Martin, 2019).

456 **Table A1. Dry aerosol properties in GEOS-Chem bulk model**

Aerosol components	R _g , μm	σ	Hygroscopicity	Refractive Index (dry, 550 nm)	ρ, g cm ⁻³	R _{eff} , μm	Q _{ext}
SNA	0.058	1.6	κ = 0.61	1.53 – 6.0×10 ⁻³ i	1.7	0.101	0.603
OM	0.058	1.6	κ = 0.1	1.53 – 6.0×10 ⁻³ i	1.3	0.101	0.603
