25 **ABSTRACT**

26 The Plio-Pleistocene is associated with many important climatic and paleoceanographic
27 changes which have shaped the biotic and abiotic nature of the modern world. The closure of the
28 Central American Seaway and the development and intensification of northern hemisphere
29 icesheets had profound global impacts on the latitudinal and vertical structure of the oceans
30 triggering the extinction and radiation of many marine groups. In particular, marine calcifying
31 planktonic foraminifera, that are sensitive to water column structure, exhibited a series of
32 extinctions as global temperatures fell. By analyzing high-resolution (~5 kyr) sedimentary records
33 from the Eastern Equatorial Pacific Ocean, complimented with global records from the novel
34 Triton dataset, we document the biotic changes in this microfossil group, within which three
35 species displayed isochronous co-extinction, and species with cold-water affinity increase in
36 dominance. We suggest that these changes are associated with the terminal stages of the closure
37 of the Central American Seaway and mark the initiation of a world in which cold- and deep-
38 dwelling species became increasingly more successful.

39 **1. INTRODUCTION**

40 Current observations suggest that the Earth is shifting from its pre-industrial state
41 (Ceballos et al., 2015; Urban 2015; Barton et al., 2016; Pinsky et al., 2018; Jonkers et al., 2019;
42 Edwards et al., 2022), and changes in the vertical and latitudinal structure of the marine realm are
43 ultimately likely to take place (Hu et al., 2011; Rhein et al., 2013; Purich et al., 2018; Zika et al.,
44 2018; Bindoff et al., 2019; Golledge et al., 2019). It is therefore important to understand how
45 ecosystems such as the open ocean, which contain resources vital to human populations (Worm
46 et al., 2003; Tittensor et al., 2010) respond to short- and long-term oceanographic shifts (e.g.,
47 Norris et al., 2013).

48 The timing of closure for the Isthmus of Panama at ~4.7-2.7 Ma (Keigwin, 1978; 1982;
49 Keller et al., 1989; Haug & Tiedemann, 1998; Haug et al., 2001; Groeneveld et al., 2006; Steph
50 et al., 2006, 2010; Molnar, 2008; Federov et al., 2013; O'Dea et al., 2016) remains contentious,
51 though the ultimate role of this event in late Cenozoic icehouse evolution is clear, proving pivotal
52 to the intensification of northern hemisphere glaciations. The precise dating of final isthmus
53 formation is less essential than the repercussions of the gradual shoaling and restriction of the
54 Central American Seaway (CAS) which triggered significant palaeoceanographic effects
55 fundamental to the evolution of the present climate state. Gradual restriction of consistent
56 throughflow between the tropical Atlantic and Indo-Pacific Oceans via isthmus formation (O'Dea
57 et al., 2016) was coupled with bipolar cryosphere development that significantly restructured
58 global vertical and meridional temperature gradients (Schmidt et al., 2004a, b; Boscolo-Galazzo
59 et al., 2021; 2022; Ford et al., 2022; Gaskell et al., 2022), altering marine ecosystems and trophic
60 structure.

61 To assess marine ecosystem changes, we look to the Cenozoic marine microfossil record,
62 specifically the planktonic foraminifera, single-celled marine protists with a global distribution and
63 the most complete Cenozoic species-level fossil record (Aze et al., 2011; Fenton & Woodhouse
64 et al., 2021). Their calcareous skeletons, or tests, preserve not only their entire life history, but
65 also a biogeochemical expression of the surrounding water column (e.g., Edgar et al., 2017).
66 These features allow for high-resolution species-specific quantification of physiological and
67 ecological adaptation through periods of climate variability (e.g., Knappertsbusch, 2007; Wade et
68 al., 2008, 2016; Hull and Norris, 2009; Wade and Olsson, 2009; Edgar et al., 2013a; Aze et al.,
69 2014; Pearson and Ezard, 2014; Weinkauf et al., 2014, 2019; Brombacher et al., 2017a, 2021;
70 Falzoni et al., 2018; Si and Aubry, 2018; Fox et al., 2020; Todd et al., 2020; Kearns et al., 2021,
71 2022; Pearson and Penny, 2021; Shaw et al., 2021; Woodhouse et al., 2021; Friesenhagen, 2022;
72 Hupp et al., 2022).

73 Here, we report the high-resolution biotic response of planktonic foraminifera during the
74 terminal stages of closure for the CAS in the Eastern Equatorial Pacific (EEP) Ocean, focusing
75 on the co-extinction of three members of the genus *Dentoglobigerina* through documentation of
76 high-resolution (~5 ka) paired single-specimen morphometric, with multi- and single-specimen
77 geochemical analyses, and their paleoceanographic implications. Furthermore, we assess the
78 global paleoecological response of planktonic foraminifera from the Pliocene to the Recent,
79 assessing the role of bipolar cryosphere development in planktonic foraminiferal
80 macroevolutionary dynamics.

81 **2. METHODS**

82 **2.1. Site Selection**

83 Integrated Ocean Drilling Program Expedition 321 Site U1338 (Hole 1338A) (2°30.469'N,
84 17°58.162'W), situated in the EEP, was drilled to 410 meters below seafloor (mbsf) through
85 Holocene - early Miocene pelagic sediments (Pälike et al., 2010). At ~3 Ma, the site was at ~2°N
86 paleolatitude (Drury et al., 2014) in a deep-water pelagic environment of similar water depth to
87 the modern (~4 km). The primary lithologies represented are calcareous, diatomaceous and
88 radiolarian nannofossil oozes and chinks. Despite the deep-water settings, and primarily
89 calcareous nature of the sediments, excellent microfossil preservation has been recorded in
90 planktonic foraminiferal specimens through intervals of this core (Fox & Wade, 2013; Woodhouse
91 et al., 2021). A preliminary assessment of core U1338A was carried out to determine the
92 approximate position of the extinction of several species of *Dentoglobigerina* (~3 Ma) based on
93 tropical biostratigraphy (Wade et al., 2011), and shipboard paleomagnetic data (Pälike et al.,
94 2010).

95

96

97 **2.2. Foraminiferal Assemblage Analysis**

98 Sediment volumes of 20-40 cm³ were collected and washed with de-ionised water over a
99 63-µm sieve; the residues were dried in an oven at 40 °C and split. All samples were examined
100 using a Zeiss Stemi 305 Compact Stereo Microscope. Planktonic foraminifers were identified
101 following the taxonomy of Kennett and Srinivasan (1983), Schiebel and Hemleben (2017), and
102 Wade et al., (2018). We performed assemblage counts on >63 µm splits yielding >300 individuals
103 (Table S1). Assessments of taxonomy and test preservation of foraminifera were performed via
104 analysis with the Tescan VEGA3 XM Scanning Electron Microscope (SEM) at the University of
105 Leeds, UK.

106 Species were grouped by their ecology to assess the relative abundances of taxa for
107 palaeoceanographic information, where taxa were assigned as either shallow- and warm-water
108 taxa (the ecogroups “symbiotic” and “asymbiotic” of Aze et al., 2011), or deep- and cold-water
109 taxa (the ecogroups “thermocline”, “subthermocline” of Aze et al., 2011, and *Globigerinita*
110 *glutinata* (Lutz, 2010)).

111 **2.3. Morphometric Analysis**

112 Specimens of the genus *Dentoglobigerina* were measured to compare species size with
113 stable isotope ratios to investigate species ecology and ontogeny. Complete specimens of
114 *Dentoglobigerina* were picked and mounted in umbilical position on card slides pierced with a fine
115 needle to accommodate the variably spired nature of species in the genus (Wade et al., 2018).
116 Specimens were imaged umbilically using a Zeiss Axio Zoom V16 microscope with attached
117 Canon EOS 100D camera at x 19.4 magnification. All specimens were then rotated 90° laterally,
118 and imaged whilst propped onto their penultimate chamber. Images were processed using the
119 image analysis software Image Pro Premier, and the maximum test diameter, previously deemed
120 a statistically repeatable measurement amongst *Dentoglobigerina* (Brombacher et al., 2017b,

121 2018; Woodhouse et al., 2021), was captured from both orientations, and the lower of the two
122 values assigned as test size.

123 **2.4. Geochemical Analysis**

124 Following morphometric analysis, well-preserved specimens of *Dentoglobigerina altispira*
125 (>200 μm), *Dentoglobigerina baroemoenensis* (>200 μm) and *Dentoglobigerina globosa* (>200
126 μm) were picked, ultrasonicated in deionized water for 10-15 seconds, and dried for stable isotope
127 analysis. This process was repeated for extant taxa representing known discrete ecological
128 habitats through the water column to determine the ecological niche habits of the extinct
129 dentoglobigerinids: *Globigerinoides ruber* (212-350 μm , surface mixed-layer (SML)),
130 *Neogloboquadrina incompta* (212-350 μm , subsurface), *Globorotalia tumida* (>300 μm ,
131 thermocline/photoc zone base, corrected for a 1.0‰ $\delta^{13}\text{C}$ enrichment due to this species
132 occupying the shallow oxygen minimum zone and consequential effects of reduced ambient pH
133 (Lohmann, 1995; Bijma et al., 1999; Uchikawa and Zeebe, 2010; Birch et al., 2013)), *Globorotalia*
134 *scitula* (212-300 μm , subthermocline), and *Cibicidoides wuellerstorfi* (>212 μm , bottom-water)
135 (see Cramer et al., 2009, 2011; Rasmussen & Thomsen, 2010; Aze et al., 2011; Woodhouse et

Figure 1. Scanning electron micrographs of species analyzed for stable isotope geochemistry. 1a, *G. ruber*, 1b, *G. ruber* shell ultrastructure showing excellent preservation, 2, *N. incompta*, 3, *G. tumida*, 4, *H. scitula*, 5, *C. wuellerstorfi*. Scale bar for images 1a, 2-5 = 100 microns, for image 1b = 10 microns. All specimens from sample U1338A-5H-4W-35/38.

137 species were analysed using an Elementar IsoPrime Dual-Inlet Isotope Ratio Mass Spectrometer
138 in the School of Earth and Environment at the University of Leeds, and data are reported to the
139 Vienna Pee Dee belemnite (VPDB) scale using a Carrara marble standard (Elemental
140 Microanalysis B2214) where analytical precision was better than 0.07 and 0.13 ‰ for $\delta^{13}\text{C}$ and
141 $\delta^{18}\text{O}$, respectively.

142 Specimens of *Cibicidoides wuellerstorfi* were also used to create a benthic foraminiferal
143 $\delta^{18}\text{O}$ record for this study to supplement the shipboard paleomagnetic data (Pälike et al., 2010).
144 This record was constructed and tuned to the Ocean Drilling Program Site 849/IODP Site 1338
145 stack constructed by Lyle et al., (2019) using QAnalySeries software (Kotov and Pälike 2018) to
146 better constrain the timing of events (see Woodhouse et al., 2021).

147 **2.5. Global Data Analysis**

148 To investigate how planktonic foraminiferal macroevolution and paleoecology has evolved
149 since the Pliocene, the Triton dataset (Fenton & Woodhouse et al., 2021) was downloaded, and
150 all macroperforate planktonic foraminiferal records occurring from 5.3-0 Ma (early Pliocene-
151 Recent) were binned into 53-time bins with equal length (100 kyrs). Species were assigned the
152 speciation and extinction datums in accordance with Aze et al., (2011) and Fenton & Woodhouse
153 et al., (2021) and all species occurrences located outside of these assigned stratigraphic ranges
154 were removed. This range trimming was applied to eliminate much of the occurrence data likely
155 attributable to misidentification and/or reworking which may create artificial “tails” within speciation
156 and extinction data (Liow et al., 2010; Lazarus et al., 2012; Flannery-Sutherland et al., 2022). The
157 trimming of taxa resulted in a dataset of 239,317 planktonic foraminiferal occurrences.
158 Furthermore, all species were assigned to their respective “ecogroups”, which represent broad
159 ecological categories based on paleoecological and phylogenetic data (Aze et al., 2011). These
160 ecogroups are defined as: ecogroup 1 = surface mixed layer dweller with photosymbionts,

161 ecogroup 2 = surface mixed layer dweller without photosymbionts, ecogroup 3 = thermocline
162 dweller, ecogroup 4 = subthermocline dweller, ecogroup 5 = high-latitude.

163 3. RESULTS

164 3.1. Assemblage Records

165 All sediments contain a highly
166 abundant well-preserved (Figure 1)
167 open-ocean planktonic foraminifer
168 assemblage comprising ~70
169 morphospecies. The dominant genera
170 through the section included
171 *Neogloboquadrina*, *Globigerinoides*,
172 *Pulleniatina*, and *Globigerinita* (see SI).
173 The isochronous extinction of the
174 species *D. altispira*, *D.*
175 *baroemoenensis*, and *D. globosa* in
176 U1338A occurs ~35.50 mbsf. There is
177 also a notable influx of the species
178 *Menardella cf. exilis* and *Menardella cf.*
179 *pertenuis* occurring from 40.56-42.58
180 mbsf, after which they are absent within
181 the study section.

182 Comparing the assemblage composition of warm- and surface- dwellers against cold- and
183 deep- dwellers, we document relatively even abundances until ~36.26 mbsf (~3.08 Ma), where

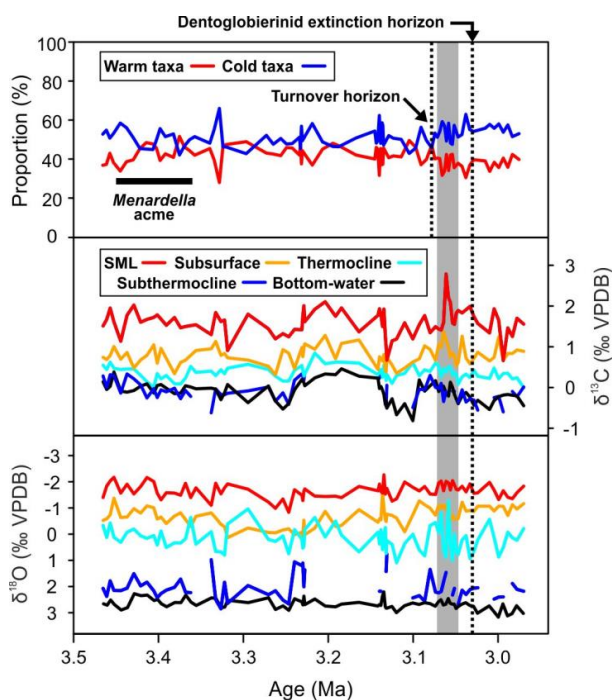

Figure 2. Grouped assemblage data of warm-water taxa (ecogroups “symbiotic” and “asymbiotic”) and cold-water taxa (ecogroups “thermocline”, “subthermocline”, and *Globigerinita glutinata* (Lutz, 2010; Aze et al. 2011). Foraminiferal $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$, black = *C. wuellerstorfi*, dark blue = *G. scitula*, cyan = *G. tumida*, orange = *N. incompta*, red = *G. ruber*. Dashed line represents permanent switch to higher proportion of cold-water taxa. Grey box indicates where isotope records exhibit high volatility.

184 the assemblage exhibits consistently greater abundances of cold- and deep-dwellers for the rest
185 of the record (Fig. 2).

186 3.2. *Dentoglobigerina* Stable Isotope-Size Trends

187 Test preservation was excellent throughout the sampled interval, where specimen walls
188 appear optically translucent, and SEM images (Fig. 1) indicate no observable diagenetic
189 alteration, clean pore spaces, and spines preserved within tests (Fig. 1a). Following artificial test
190 breaking, inspection of the wall ultrastructure (Fig. 1b) showed that no wall recrystallisation had

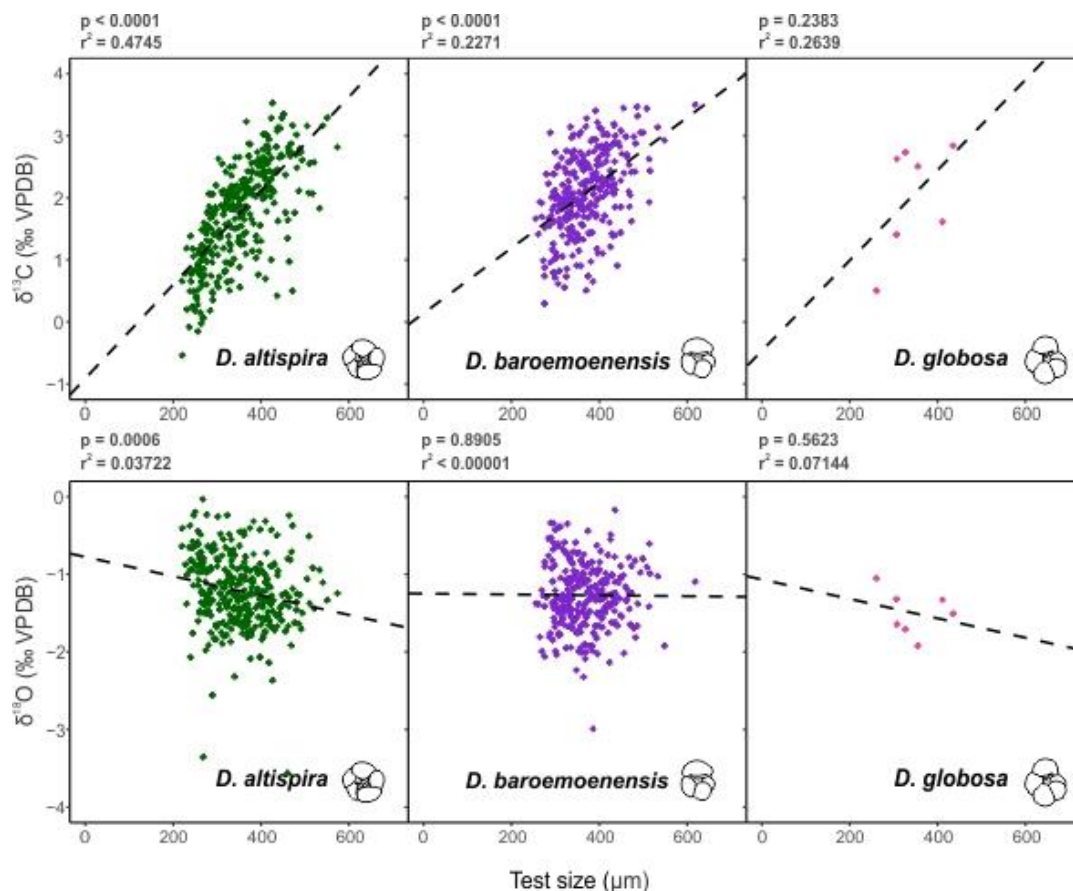

Figure 3. Test size - $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ relationships for the three species of *Dentoglobigerina* which underwent extinction through the study section. Trend lines for each species represent linear regressions based on the entire per species dataset (dashed line). Significance (p) and measure of fit (r^2) were calculated for each linear regression.

191 taken place, suggesting stable isotope signals remain unaltered (Sexton et al., 2006; Edgar et al.,
 192 2013b). Single-specimen $\delta^{13}\text{C}$ values for *D. altispira*, *D. baroemoenensis*, and *D. globosa* vary
 193 from -0.54 to +3.53‰, +0.30 to +3.50‰, and +0.51 to +2.84‰ (Fig. 3, SI), respectively, whilst
 194 $\delta^{18}\text{O}$ values vary from -3.56 to -0.03‰, -2.99 to -0.17‰, and -1.92 to -1.05‰, respectively. In all
 195 three species, a positive correlation is calculated between test size and $\delta^{13}\text{C}$, however, this
 196 relationship is only significant ($p < 0.0001$) in *D. altispira* and *D. baroemoenensis*, potentially due
 197 to the greater number of specimens analyzed for these species (Fig. 3). Regression slopes are
 198 similarly steep, however the slopes for *D. altispira* and *D. globosa* are more alike. *D.*
 199 *baroemoenensis* and *D. globosa* show no significant correlation between $\delta^{18}\text{O}$ and test size,
 200 however, a significant ($p = 0.0006$) negative relationship is recorded in *D. altispira*. Once again,
 201 regression slopes for *D. altispira* and *D. globosa* are similar, whereas for *D. baroemoenensis*, this
 202 slope is almost flat (Fig. 3).

203 3. 3. Extant Species 204 Geochemical Records

205 Amongst the extant
 206 species picked from strict size
 207 fractions throughout the study
 208 section, *G. ruber* $\delta^{13}\text{C}$ values show
 209 the highest $\delta^{13}\text{C}$ variability (+0.7 to
 210 +2.8‰), and $\delta^{18}\text{O}$ values varying
 211 from -2.3 to -0.8‰ (SI, Fig. 4).
 212 Corrected *G. tumida* values show
 213 the lowest $\delta^{13}\text{C}$ variability (0 to
 214 +0.8‰), and the highest variability
 215 for $\delta^{18}\text{O}$ (-1.3 to +1.1‰). *G. scitula*

Figure 4. $\delta^{13}\text{C}$ and $\delta^{18}\text{O}$ cross-plot 2 showing mean values of all analyzed specimens from this study. Black = *C. wuellerstorfi*, dark blue = *G. scitula*, cyan = *G. tumida*, orange = *N. incompta*, red = *G. ruber*, green = *D. altispira*, purple = *D. baroemoenensis*, pink = *D. globosa*. Species marked with an asterisk are benthic.

216 $\delta^{13}\text{C}$ values vary from -0.6 to +0.4‰, whilst $\delta^{18}\text{O}$ varies from +0.8 to +2.9‰, whereas bottom-
217 water *C. wuellerstorfi* $\delta^{13}\text{C}$ values vary from -0.8 to +0.5‰, and $\delta^{18}\text{O}$ varies +2.2 to +3.1‰,
218 showing the lowest variability in $\delta^{18}\text{O}$ (Fig. 4). The stable isotope records of extant species
219 generally tend to show low inter-sample variability, however there is notable geochemical
220 stochasticity within the *G. tumida* record ~36.17-35.86 mbsf (Fig. 2).

221 All three species of *Dentoglobigerina* analyzed in this study record mean stable isotopic
222 ratios similar to the extant species *G. ruber*, where all species indicated $\delta^{18}\text{O}$ ratios less negative
223 than *G. ruber*, and *D. baroemoenensis* and *D. globosa* show $\delta^{13}\text{C}$ ratios more positive than this
224 species (Figs. 3 and 4).

225 3.4. Global Pliocene-Recent Ecogroup trends

226 The global proportions of planktonic foraminiferal ecogroups within the Triton dataset
227 (Fenton & Woodhouse et
228 al., 2021) show that
229 throughout the time
230 interval studied (5.3-0
231 Ma), surface mixed layer
232 dwellers without
233 photosymbionts (orange)
234 proportions remain
235 relatively consistent,
236 making up ~10% of the
237 total global fauna (Fig. 5).

238 From 5.3-3 Ma, global
239 ecogroup proportions are
240 relatively consistent,

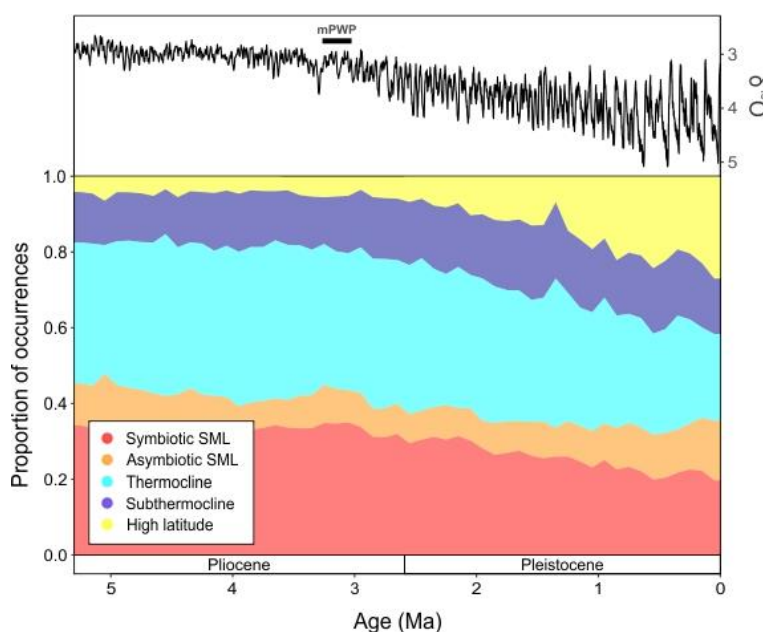

Figure 5. The LR04 stack showing benthic foraminiferal $\delta^{18}\text{O}$ (from Lisiecki and Raymo, 2005), and proportions of macroperforate planktonic foraminifera occurrences assigned to the ecogroups of Aze et al. (2011), binned to 100 kyrs from 5.3 Ma to the Recent. mPWP = mid-Pliocene Warm Period, SML = surface mixed-layer.

241 where the dominant forms are thermocline dwellers (cyan) and surface mixed layer dwellers with
242 photosymbionts (red) (Fig. 5), making up ~40% and ~35% of the global fauna, respectively.
243 During this interval, the proportion of subthermocline dwellers (blue) and high-latitude forms
244 (yellow) also remain relatively consistent with ~10% and <5% of total proportions, respectively.
245 After ~3 Ma, both thermocline dwellers and surface mixed layer dwellers with photosymbionts
246 show a steady decline in global representation approaching the Recent, making up ~20% each
247 in the modern ocean. At ~3 Ma, both the subthermocline dwellers and high-latitude ecogroup start
248 to show increases in their proportions, though this increase approaching the modern is much
249 greater in the latter group. During the last 100 kyrs, subthermocline and high latitude species
250 constitute ~15 and ~25%, respectively (Fig. 5).

251 4. DISCUSSION

252 Few major changes in the assemblage composition are observed through the study
253 interval other than the isochronous extinction of *D. altispira*, *D. baroemoenensis*, and *D. globosa*
254 at ~3.037 Ma (35.50 mbsf), and the influx of *M. cf. exilis* and *M. cf. pertenuis* through 3.45-3.36
255 Ma (Fig. 2; 42.58-40.56 mbsf). The extinction of *D. altispira* is a useful marker in the mid-Pliocene,
256 previously recorded within the East Equatorial Pacific Ocean (3.46 Ma; Shackleton et al., 1995;
257 Wade et al., 2011), however this study and that of Woodhouse et al., (2021) provide recalibration
258 for this event, which includes the co-extinction of *D. baroemoenensis* and *D. globosa*.

Species	Pore density (per 2500 μm^2)
<i>M. menardii</i>	32
<i>M. limbata</i>	27
<i>M. cf. exilis</i>	51
<i>M. cf. pertenuis</i>	49

Table 1. The number of pores per 2500 μm^2 in the penultimate chamber of select species of *Menardella*.

259 The co-extinction of the dentoglobigerinids is significant, as Woodhouse et al., (2021)
260 demonstrated that *D. altispira* and *D. baroemoenensis* show unique phenotypic responses
261 leading up to their termination, despite their shared phylogenetic and ecological affinity. We
262 therefore suggest that all three species share an ecological habit that ultimately proved inefficient
263 to mitigate the changing abiotic conditions associated with this critical period of bipolar cryosphere
264 development (Kleiven et al., 2002; Brierly & Fedorov, 2010; Cramer et al., 2009, 2011; Willeit et
265 al., 2015; Hayashi et al., 2020; Westerhold et al., 2020).

266 The documented co-occurrence of *M. cf. exilis* and *M. cf. pertenuis* may also indicate a
267 shared ecological affinity between these species (Fig. 2; Kennett & Srinivasan, 1983;
268 Knappertsbusch, 2016). Furthermore, this association may suggest that these two similar forms
269 exist within the same genetic species complex, though further study on internal shell ontogeny

Figure 6. Scanning electron micrographs of select species of *Menardella* and pore detail of penultimate chambers. 1a, *M. menardii*, 1b, *M. menardii* pore detail, 2a, *M. limbata*, 2b, *M. limbata* pore detail, 3a, *M. cf. exilis*, 3b, *M. cf. exilis* pore detail, 4a, *M. cf. pertenuis*, 4b, *M. cf. pertenuis* pore detail. Scale bar for images 1a, 2a, 3a, 4a = 200 microns, for image 1b, 2b, 3b, 4b = 50 microns. Specimens 1 and 2 from sample U1338A-5H-CC-11/14, and specimens 3 and 4 from sample 1338A-5H-7W-76-79.

270 and external morphology would be required to confirm this hypothesis. Notably however, Kaneps
271 (1970) and Chaisson (2003) have suggested that Indo-Pacific occurrences of these two species
272 are in fact “aberrant” forms of *Menardella limbata* and *Menardella menardii*, with the *M. exilis-*
273 *pertenuis* plexus being solely endemic to the Atlantic basin (Sexton & Norris, 2011).

274 Scanning electron photomicrographs and pore density analysis of *Menardella*
275 morphospecies within this study (Fig. 6; Table 1) suggests that the *M. cf. exilis* and *M. cf. pertenuis*
276 morphotypes ascribed to “aberrant” forms may in fact be phylogenetically distinct from both *M.*
277 *menardii* and *M. limbata*, as well as from the endemic Atlantic *M. exilis-pertenuis* plexus. Where
278 the Atlantic type-specimens exhibit finely perforate tests (Kennett & Srinivasan, 1983), the
279 specimens within this study appear to show test perforation intermediate between “normally
280 perforate” menardellids such as *M. menardii* and *M. limbata* (Fig. 6), and the “finely perforate” *M.*
281 *exilis-pertenuis* plexus (Kennett and Srinivasan, 1983; Chaisson, 2003). Whether all Indo-Pacific
282 occurrences of these morphotypes (e.g., Brönniman and Resig, 1971; Jenkins and Orr, 1972;
283 Thunell, 1981; Keigwin, 1982; Thompson, 1982; Chaisson and Leckie, 1993) exhibit similar test
284 perforation remains to be determined. However, these forms could represent either: 1) convergent
285 evolution of a geographically-isolated endemic population restricted to the Indo-Pacific triggered
286 by vicariance, or 2) specimens within the *M. exilis-pertenuis* plexus exhibiting a differential
287 phenotypic expression of pore density, potentially due to regional differences in
288 paleoceanography between the Atlantic and Indo-Pacific basins at this time (Haug et al., 2001).
289 Irrespective of the biological implications, this acme event may represent a regionally valuable
290 biostratigraphic marker horizon.

291 Comparing the assemblage composition of warm- and surface- dwellers against cold- and
292 deep- dwellers, we document a gradual turnover from an assemblage exhibiting relatively even
293 abundances of these two groups, to one of increasing occupation of cold- and deep-dwellers from
294 ~3.08 Ma onwards (36.26 mbsf; Fig. 2). This may reflect regional thermocline shoaling similar to

295 patterns observed at DSDP Site 84 in the proximal Panama Basin (Lutz, 2010). Other geological
296 intervals associated with significant global cooling such as the Eocene-Oligocene transition and
297 late Miocene cooling exhibit similar patterns of gradual, successive turnover of warm-water
298 dwellers by cold-water taxa potentially associated with expansions/contractions in their respective
299 ecospace (Keller, 1983; Boersma and Premoli Silva, 1991; Keller et al., 1992; Molina et al., 1993;
300 Wade and Pearson, 2008; Ezard et al., 2011; Lowery and Fraass, 2019; Lowery et al., 2020;
301 Boscolo-Galazzo et al., 2021, 2022).

302 **4.1. Dentoglobigerinid Paleoecology**

303 Studies of extant species suggest a strong positive correlation between planktonic
304 foraminifera $\delta^{13}\text{C}$ and test size, paired with a lack of a strong negative significant relationship in
305 $\delta^{18}\text{O}$ and test size, is indicative of species bearing photosymbiotic algae (e.g. Berger et al., 1978;
306 Bouvier-Soumagnac and Duplessey, 1985; Spero and Williams, 1988, 1989; Spero et al., 1991;
307 Spero, 1992; Spero and Lea, 1993; Ravelo and Fairbanks, 1995; Norris, 1996; Birch et al., 2013).
308 Our data suggests that all three species of *Dentoglobigerina* studied here are symbiont-bearing,
309 displaying mean stable isotope data similar to the symbiont-bearing surface mixed layer dwelling
310 *G. ruber* (Figs. 2-4). Moreover, the regression lines for the ancestor-descendent pair *D. globosa*
311 - *D. altispira* are remarkably similar, suggesting the species share similar stable isotope-test size
312 relationships, despite the speciation of *D. altispira* occurring ~20 Myrs prior (Aze et al., 2011;
313 Wade et al., 2011, 2018). However, the substantially fewer data for *D. globosa* currently limits the
314 significance of this observation for this particular species (Fig. 3).

315 The results presented here contribute to the variety of interpretations from previous
316 studies on the paleoecology of *D. altispira*. Spanning different ocean basins throughout the
317 species' stratigraphic range they suggest: a shallow-dwelling (e.g., Keller and Savin, 1985;
318 Vincent et al., 1985; Prentice and Matthews, 1988; Corfield and Cartlidge, 1991; Norris et al.,
319 1993; Hodell and Vayavananda, 1994; Sosdian and Lear, 2020), deep-dwelling (Opdyke and

320 Pearson, 1995; Pearson and Shackleton, 1995), or lower mixed layer/upper thermocline (Zou et
321 al., 2022) ecological niche habit.

322 Woodhouse et al., (2021) suggested that prior to extinction, the *D. altispira* geochemical
323 signal may signify that this species underwent adaptive ecological niche migration across multiple
324 depth habitats. Upon further investigation, by isolating all *D. altispira* specimens present after the
325 migration horizon at ~ 3.061 Ma (Woodhouse et al., 2021), we show that these specimens do in
326 fact display a steeper negative relationship between $\delta^{18}\text{O}$ and test size (Fig. S1), consistent with
327 asymbiosis, however this relationship lacks statistical significance. Nevertheless, this observation
328 lends support to the conclusions of Woodhouse et al., (2021) that this species underwent niche
329 adaptation prior to extinction.

330 Another plausible scenario may be the existence of indeterminate cryptic diversity within
331 the *D. altispira* morphospecies complex where multiple ecological strategies or phylogenetic
332 expressions may be present (e.g., Huber et al., 1997; Bijma et al., 1998; de Vargas et al., 1999,
333 2002; Weiner et al., 2012; Schiebel and Hemleben, 2017; Nirmal et al., 2021; Pearson and Penny,
334 2021), and the stepwise changes observed in Woodhouse et al., (2021), may indicate the
335 systematic loss of “cryptic genotypes” within this morphospecies complex. Indeed, Pearson and
336 Penny (2021), hypothesized that dramatic abundance switches in the Indo-Pacific Warm Pool of
337 ecologically-distinct alternately-coiled populations of *Pulleniatina* morphospecies may signify
338 replacement by distinct cryptic genotypes, and such coiling switches are noted throughout the
339 planktonic foraminiferal fossil record (Ericson et al., 1955; Saito et al., 1975; Bossio et al., 1976;
340 Hallock & Larsen. 1979; Hornibrook, 1982; Scott et al., 1990; Norris and Nishi, 2001; Winter and
341 Pearson, 2001; Crundwell & Nelson, 2007; Wade et al., 2011; Pearson & Ezard, 2014; Crundwell,
342 2015a, b; Levin et al., 2016; Wallace et al., 2019; Crundwell & Woodhouse, 2022a, b). Therefore,
343 the range of interpreted paleoecologies in *D. altispira* may in fact be due to the occurrence of
344 distinct cryptic populations from across the geological record. Irrespective, the abiotic conditions

345 at this time appear to have become fatally detrimental to the entire ecological habit of all three
346 morphospecies of *Dentoglobigerina* analyzed in the EEP, and subsequently across the entire
347 globe (Shackleton et al., 1995; Chaisson and Pearson, 1997; Wade et al., 2011; Raffi et al., 2020;
348 Groeneveld et al., 2021; Woodhouse et al., 2021).

349 **4.2. Pliocene EEP Paleoceanography**

350 The establishment of the Isthmus of Panama played a key role in Atlantic Meridional
351 Overturning Circulation intensification by barring Caribbean inflow from the Atlantic (O’Dea et al.,
352 2016; Hayashi et al., 2020), leading to a new palaeoceanographic state defined by an equatorial
353 Pacific thermocline exhibiting a high-angle east-west tilt (Fiedler and Talley, 2006; Yang and
354 Wang, 2009; Zhang et al., 2012; Ford et al., 2015). Changes in the EEP water column structure
355 are compounded within biotic and abiotic records, where global changes in ice volume, as shown
356 by benthic $\delta^{18}\text{O}$ (Fig. 5), and the formation of the isthmus contributed to the gradual cooling and
357 shoaling of the thermocline (Ford et al., 2015). Isochronous records of ice-rafted debris in the
358 North Atlantic and Pacific infer a substantial change to high-latitude global climate ~3 Ma
359 (Shackleton et al., 1984; Maslin et al., 1996; Kleiven et al., 2002; Lawrence et al., 2006).
360 Consequently, the already restricted CAS was likely subjected to substantial eustatic sea level
361 fluctuations (Chaisson, 2003; Bartoli et al., 2005; O’Dea et al., 2016), causing cool water within
362 or below the thermocline to become shallow enough to be mixed by surface winds (Philander &
363 Federov, 2003; Federov et al., 2004; 2006; Ford et al., 2012; 2015). In turn, this contributed to a
364 dramatic increase in regional upwelling associated with further development of the EEP cold
365 tongue (Herbert et al., 2010). We suggest that the increasing dominance of cold- and deep-
366 dwellers in the EEP (Figs. 2 and 5) are a direct manifestation of the water column structure
367 changes associated with closure of the CAS and cryosphere intensification, marking the initiation
368 of transition from the early Pliocene “El Padre” mean state to one more similar to the modern
369 ocean (Seki et al., 2012; Ford et al., 2012, 2015).

370 The geochemical fluctuations noted within *G. tumida* from 3.071-3.061 Ma (36.17-35.86
371 mbsf; Fig. 2) are coeval with the interval assigned to the “Phase Transition” by Woodhouse et al.,
372 (2021), in which *D. altispira* and *D. baroemoenensis* exhibit dramatic fluctuations in size and
373 shape preceding rapid ecological changes. Here, the $\delta^{18}\text{O}$ signal of *G. tumida* exhibits substantial
374 and rapid changes up to $\sim 2.1\text{‰}$, switching from typical thermocline values to those indicative of
375 the subsurface, and back again, whereas all other water column $\delta^{18}\text{O}$ value changes are nominal
376 (Fig. 2).

377 If the fluctuations within the $\delta^{18}\text{O}$ signal of *G. tumida* were related to fluctuations in its
378 depth habitat, we would expect the inverse pattern to occur in its $\delta^{13}\text{C}$ signature, as $\delta^{13}\text{C}$ values
379 decrease with depth (Cannariato and Ravelo, 1997; Ford et al., 2012; Birch et al., 2013), however
380 this is not the case (SI, Fig. 2). The maximum $\delta^{18}\text{O}$ excursion value ($\sim 2.1\text{‰}$) is equivalent to a
381 temperature change of $\sim 10\text{ °C}$, based on a mid-Pliocene SMOW value of -0.3‰ (Williams et al.,
382 2005; Medina-Elizalde, Lea and Fantle, 2008; Tindall & Haywood, 2015) and the
383 paleotemperature equations of Kim & O’Neil (1997). Previous studies from EEP sites show
384 Mg/Ca-derived thermocline temperature fluctuations of $\sim 3\text{ °C}$ (Site 1241; Steph et al., 2006) to ~ 5
385 °C (Sites 848, 849, and 853; Ford et al., 2012) across the same interval, and modern ocean
386 seasonal deviations within EEP surface waters are minor at $\pm 1\text{ °C}$ (Fiedler, 1992). However, these
387 can be intensified by El Niño conditions by up to $+3.8\text{ °C}$ (Pérez-Angel & Molnar, 2017).

388 Modern regional evaporation-precipitation balance within the EEP too shows very little
389 variation, wherein $\delta^{18}\text{O}_{\text{sw}}$ values average 0.26‰ (Fairbanks et al., 1992), ranging from $\sim 0.2\text{‰}$ - 0.5‰
390 for the entire tropical Pacific (Ravelo & Hillaire-Marcel, 2007). Factors other than temperature and
391 salinity (e.g., chlorophyll *a*, lunar cycle) which trigger species-specific habit changes (Rebotim et
392 al., 2017) could be at least partially responsible for these dramatic changes in the *G. tumida* $\delta^{18}\text{O}$
393 records, however this species is known to calcify at the base of the photic zone (Ravelo &

394 Shackleton, 1995), irrespective of thermocline depth (Ravelo & Fairbanks, 1992; Rincon-Martinez
395 et al., 2011).

396 Despite the present low range in Pacific equatorial $\delta^{18}\text{O}_{\text{sw}}$ values, modern Atlantic-
397 Caribbean surface waters record a salinity value $\sim 3\text{‰}$ less than the modern EEP (Haug et al.,
398 2001; Garcia et al., 2006; Schmidt et al., 2016; Ögretmen et al., 2020), equating to $\sim 1.5\text{‰}$ lower
399 in mean $\delta^{18}\text{O}_{\text{sw}}$ values (Ravelo and Hillaire-Marcel, 2007). This salinity contrast was fully
400 established by ~ 4.2 Ma (Haug et al., 2001), and consistent breaching of Atlantic-Caribbean waters
401 over the still-submerged isthmus may have occurred as late as 1.9 Ma (Coates and Obando,
402 1996; Keller et al., 1989; Schmidt et al., 2016). Therefore, a breaching event is the most probable
403 cause for the substantial variations in the $\delta^{18}\text{O}$ record of *G. tumida* from 3.071-3.061 Ma, where
404 this apparently thermocline-restricted (Fig. 2) disturbance may have contributed to disruption of
405 the *Dentoglobigerina* ecological niche habit at this time (Woodhouse et al., 2021).

406 **4.3. Plio-Pleistocene Global Ecogroup and Evolutionary Patterns**

407 It appears the faunal turnover documented in the EEP at ~ 3.08 Ma (Fig. 5) may represent
408 a critical point in the development of the bipolar cryosphere which typifies the Pleistocene and
409 Holocene (Kleiven et al., 2002; Brierly & Fedorov, 2010; Cramer et al., 2009, 2011; Willeit et al.,
410 2015; Hayashi et al., 2020; Westerhold et al., 2020). Major Antarctic icesheet expansion
411 (Shevenell et al., 2004; Holbourn et al., 2015; Frigola et al., 2018; Westerhold et al., 2020)
412 following the Miocene Climatic Optimum (~ 17 -15 Ma; Methner et al., 2020) initiated global cooling,
413 intensifying meridional gradients (Gaskell et al., 2022). This triggered unprecedented mean size
414 increases in low-latitude planktonic foraminifera (Schmidt et al., 2004a, b) and higher efficiency
415 of the biological carbon pump, promoting greater endemism and exploitation of new deep-water
416 niches in calcifying plankton (Olsson, 1982; Scott, 1982; Keller, 1985; Malmgren & Berggren,
417 1987; Scott et al., 1990; Norris et al., 1993, 1994; 1996; Norris, 1999, 2000; Rögl, 1999; Chaisson,

418 2003; Kucera & Schönfeld, 2007; Ezard et al., 2011; Crundwell, 2018; Rosenthal et al., 2018;
419 Spezzaferri et al., 2018; Lam and Leckie, 2020; Boscolo-Galazzo et al., 2021, 2022).

420 From ~6.5 Ma, the equatorial Pacific shows meridionally distinct planktonic foraminiferal
421 faunal provinces, that display a turnover in dominance from Miocene species to more Recent taxa
422 ~4 Ma (Chaisson, 1995; Chaisson and Ravelo, 2000) linked with the closure of the CAS (Haug et
423 al., 2001). Global temperatures record a gradual, stable decline towards ~3 Ma (Fig. 5;
424 Westerhold et al., 2020), after which planktonic foraminiferal morphospecies diversity shows a
425 notable decline (Aze et al., 2011; Ezard et al., 2011; Fraass et al., 2015; Lowery et al., 2020),
426 whilst ecogroups (Fig. 5) exhibit the expansion of cold-water forms coincident with the
427 development and intensification of northern hemisphere icesheets (Kleiven et al., 2002; Brierly &
428 Fedorov, 2010; Cramer et al., 2009, 2011; Willeit et al., 2015; Hayashi et al., 2020). The greater
429 proportion of cold- and deep-dwellers in the EEP at ~3.08 Ma (Fig. 2) coincides with global
430 ecogroup patterns (Fig. 5), signifying the initiation of increasing global dominance of planktonic
431 foraminiferal species with cold-water affinity, alongside many other phylogenetic groups (Slater
432 et al., 2017; Steinthorsdottir et al., 2020), as the world descended into a bipolar Icehouse state.

433 Despite the reduction in morphospecies diversity from ~3 Ma, the late Cenozoic closure
434 of the Tethyan and Central American Seaways (Crame & Rosen, 2002; Brierly & Fedorov, 2010;
435 Hamon et al., 2013; Matthews et al., 2016) may have contributed to the notable rise in diversity
436 through the Neogene (Aze et al., 2011; Ezard et al., 2011; Peters et al., 2013; Fraass et al., 2015;
437 Lowery et al., 2020), due to a significantly more heterogenous ocean structure via longitudinal
438 obstruction of tropical/subtropical waters by continental reconfiguration, and latitudinal partitioning
439 caused by the steepening of global meridional temperature gradients (Haug et al., 2001; Schmidt
440 et al., 2004a, b; Knappertsbusch, 2016; Ford et al., 2022; Friesenhagen, 2022; Gaskell et al.,
441 2022). Moreover, this intensified, heterogenous Icehouse climate may have played a significant
442 role in shaping the incredible diversity observed within modern planktonic foraminiferal cryptic

443 genotypes (Darling & Wade, 2008; Aurahs et al., 2009; Morard et al., 2009, 2013, 2019; Ujjié et
444 al., 2010; Norris & Hull, 2012; Weiner et al., 2012; 2014; André et al., 2014; Ujjié & Ishitani, 2016),
445 though further work is required on the quantification of planktonic foraminiferal cryptic diversity
446 within deep time (André et al., 2013).

447 It should be noted however, that there is a prominent increase in sampling of Quaternary
448 high latitudes that is yet to be replicated in deep-time marine records (Lazarus, 1994; Diepenbroek
449 et al., 2002; Sellén et al., 2010; O'Regan, 2011; Siccha & Kučera 2017; Waelbroeck et al., 2019;
450 Renaudie et al., 2020; Fenton & Woodhouse et al., 2021). This is due to the difficulties
451 encountered in deep-sea scientific drilling of higher latitudes through the combined impacts of
452 unpredictable and detrimental oceanographic conditions, and ephemeral sea ice (Barker et al.,
453 1977; Backman et al.; 2006; Lamy et al., 2019; McKay et al., 2019). Consequently, the substantial
454 increase in cold-water forms observed from ~3 Ma to the Recent (Fig. 5) may be at least partly
455 driven by sampling efforts.

456 5. CONCLUSIONS

457 The high-resolution planktonic foraminiferal biotic record at IODP Site U1338
458 chronicles important changes in late Cenozoic development of global climate and the evolutionary
459 history of this microfossil group. The co-extinction of three species of *Dentoglobigerina*, and the
460 acme of *M. cf. exilis* and *M. cf. pertenuis* signify useful regional biostratigraphic markers within
461 the Pacific chronological framework, where the former appears to be associated with abiotic
462 changes in water column structure associated with the close of the Central American Seaway,
463 and intensification of bipolar cryosphere development. These three extinct dentoglobigerinids
464 appear to exhibit a symbiotic, mixed layer ecological niche habit, however the compilation of
465 results from previous studies may suggest a high degree of unknown cryptic diversity within
466 dentoglobigerinid morphospecies complexes. The abiotic extinction mechanism likely signifies the
467 initiation of a critical stage in the formation of northern hemisphere icesheets and the
468 accompanying changes to global paleoceanography and water column structure, where cold- and
469 deep-dwelling species start to become more dominant across the globe. As the Earth continues
470 to shift away from the pre-industrial state, it becomes increasingly difficult to predict the response

471 of marine organisms to any impending climatic perturbations. However, anthropogenic forcing
472 has the capability to melt modern continental-scale ice sheets which hold the potential to
473 dramatically disrupt global ocean circulation patterns, nutrient distributions, and water column
474 structure. Based on past changes in such systems, this may signify impending repercussions for
475 planktonic foraminiferal biodiversity, and other planktonic groups whose survival depends on the
476 vertical structure of the oceanic water column.

477 **Author Contribution:** A.W., F.A.P., S.L.J., R.A.J., and R.J.N. generated the data. All authors
478 contributed to the interpretation of the data. A.W. plotted figures and wrote the R code to perform
479 statistical analysis. F.A.P. collected SEM images. A.W. and T.A. contributed to the writing and
480 editing of the manuscript.

481 **Code availability:** N/A

482 **Data availability:** All data included in supplementary information.

483 **Sample availability:** All samples available upon request.

484 **Competing interests:** The authors declare that they have no conflict of interest.

485 **Acknowledgements**
