19 **Abstract**

20 Saharan dust aerosols are often embedded in tropical easterly waves, also known  
21 as African easterly waves, and are transported thousands of kilometers across the tropical

1 Atlantic Oceans, reaching the Caribbean Sea, Amazon Basin, and the eastern U.S.  
2 However, due to the complex climate dynamics of West Africa and the eastern tropical  
3 Atlantic Ocean, there is still a lack of understanding of how dust particles may influence  
4 the development of African easterly waves, which are coupled to deep convective systems  
5 over the tropical Atlantic Ocean and in some cases may seed the growth of tropical  
6 cyclones. Here we used 22 years of daily satellite observations and reanalysis data to  
7 explore the relationships between dust in the Saharan air layer and the development of  
8 African easterly waves. Our findings show that dust aerosols are not merely transported by  
9 the African easterly jet and the African easterly waves system across the tropical Atlantic  
10 Ocean, but also contribute to the changes in the eddy energetics of the African easterly  
11 waves.

12         The efficiency of dust radiative effect in the atmosphere is estimated to be a  
13 warming of approximately  $20 \text{ Wm}^{-2}$  over the ocean and  $35 \text{ Wm}^{-2}$  over land. This diabatic  
14 heating of dust aerosols in the Saharan Air Layer acts as an additional energy source to  
15 increase the growth of the waves. The enhanced diabatic heating of dust leads to the  
16 increase in meridional temperature gradients in the baroclinic zone, where eddies extract  
17 available potential energy from the mean-flow and convert it to eddy kinetic energy. This  
18 suggests that diabatic heating of dust aerosols can increase the eddy kinetic energy of the  
19 African easterly waves and enhance the baroclinicity of the region. Our findings also show  
20 that dust outbreaks over the tropical Atlantic Ocean precede the development of baroclinic  
21 waves downstream of the African easterly jet, which suggests that the dust radiative effect  
22 has the capability to trigger the generation of the zonal and meridional transient eddies in  
23 the system comprising the African Easterly Jet and African easterly waves.

## 1   **1    Introduction**

2           African Easterly Waves (AEWs), also known as tropical Atlantic easterly waves,  
3 are synoptic-scale atmospheric disturbances with a preferred wavelength in the 2000-  
4 4000km range that often develop into tropical Atlantic cyclones (Dunn, 1940). The basic  
5 characteristics and behavior of the AEWs have been described in previous studies (Charney  
6 and Stern, 1962; Chang, 1993; Kiladis et al., 2006; Diaz and Aiyyer, 2013). Local heating  
7 is a dominant factor in determining the growth of AEWs over West Africa (Norquist et al.,  
8 1977), such that the presence of diabatic heating near the entrance of the African Easterly  
9 Jet (AEJ) is a favorable factor in generating AEWs (Thorncroft et al., 2008; Russell et al.,  
10 2020). The localized mid- to lower-tropospheric heating generates vortices in the vicinity  
11 of the AEJ core, which is the genesis of the AEWs (Thorncroft et al., 2008; Berry and  
12 Thorncroft, 2012). AEWs can be initiated by convective triggers over the highlands of  
13 eastern Africa and forcing from the subtropical Atlantic storm track (Cornforth et al. 2009).

14           Several studies have shown that AEWs are intensified in the presence of convective  
15 systems where the mesoscale convection and synoptic-scale AEWs are dynamically  
16 coupled (Kiladis et al., 2006; Hsieh and Cook, 2005&2007; Berry and Thorncroft, 2012).  
17 A large portion of tropical Atlantic cyclones and hurricanes evolve from the AEWs (Avila  
18 and Clark, 1989; Avila and Pasch, 1992; Pasch and Avila, 1994) during the boreal summer  
19 seasons, which is the season when the amplitude of AEWs peaks (e.g., Roundy and Frank,  
20 2004).

21           Numerous studies addressed the dynamics of the AEWs; however, the impacts of  
22 aerosol radiative effects on the energy of the AEWs are poorly understood. The Sahara  
23 Desert in North Africa is the largest source of dust in the world, where over sixty million

1 tons of dust particles (e.g., Prospero and Lamb, 2003; Lau and Kim, 2007) are lifted  
2 annually and transported within the Saharan Air Layer (SAL) across the Atlantic Ocean  
3 (Carlson and Prospero, 1972) and reaches the Caribbean Sea, the Gulf of Mexico, Amazon  
4 Basin and the United States (e.g., Perry et al., 1997; Liu et al., 2008, Francis et al., 2020).  
5 Dust particles in the SAL have a robust influence on regional and global climate through  
6 their impacts on radiation, clouds, hydrological cycle, and atmospheric circulation  
7 (Colarco et al., 2003; Lau et al., 2009; Wilcox et al., 2010; Kim et al., 2010). In particular,  
8 among aerosol species, dust is known for having a strong shortwave radiative effect by  
9 both efficiently scattering, as well as absorbing, incoming radiation and leading to a heating  
10 of the dust layer and strong cooling of the surface (Myhre et al., 2004; Mamun et al., 2021,  
11 Francis et al., 2022). The shortwave radiative effect is slightly counteracted by the  
12 longwave radiative effect of dust which causes warming at the surface and cooling within  
13 the atmosphere (Meloni et al., 2018).

14         A limited number of studies have focused on the impacts of Saharan dust plumes  
15 on the dynamics of the AEWs (Jones et al., 2003; Ma et al., 2012; Hosseinpour and Wilcox,  
16 2014). Jones et al. (2004) suggested that dust optical and radiative properties have  
17 significant impacts on the AEWs. They showed that the low-level temperature anomalies  
18 associated with the AEWs are modulated by the dust radiative effect and suggested that  
19 dust loading in the SAL precedes the maximum geopotential height at 700-hPa by about  
20 1-2 days. Model sensitivity studies have also shown that the intensification of AEWs can  
21 be induced by dust (Ma et al., 2012; Grogan et al., 2019; Bercos-Hickey and Patricola,  
22 2021; Grogan et al., 2022). The analytical and numerical study of Grogan et al. (2016)  
23 found that the presence of dust enhances the development of AEWs by providing a

1 buoyancy source. They also showed that dust can affect the propagation of AEWs by  
2 changing the wind shear and stability of the atmosphere. Using a regional climate model  
3 coupled with a dust model, Bercos-Hickey et al. (2017) found that Saharan dust causes  
4 AEJ to shift northward, upward, and westward, and this results in westward expansion and  
5 the northward shift of both the northern and southern tracks of the AEWs. Satellite  
6 observations support this notion by showing that a similarity exists between the pattern of  
7 temperature and wind anomalies of the AEWs and those associated with the dust outbreaks  
8 (Hosseinpour and Wilcox, 2014).

9         Saharan dust is not the only contributor to aerosol radiative effect over Africa and  
10 the Atlantic Ocean. Previous studies showed that smoke transport from biomass burning  
11 can reach up to ~ 3-5 km altitude, which is above the stratocumulus clouds over the Sahel  
12 region, and may affect the radiation through aerosol direct and indirect effects (Redemann  
13 et al., 2021). Biomass burning in Africa is closely related to seasonal rainfall variability  
14 and the location of the Intertropical Convergence Zone (ITCZ); thus, the emissions from  
15 biomass burning in North Africa occur in boreal spring and winter, when ITCZ is south  
16 of the equator (e.g., Cahoon et al., 1992; Barbosa et al., 1999; Ramo et al., 2020). During  
17 the boreal winter, smoke aerosols are maximized over the Sahel region (Figure 1,  
18 Haywood et al., 2008), where the northward transport of smoke merges with dry  
19 southward and westward transport of dust aerosols. This leads to the co-existence of dust  
20 and smoke, as smoke is dominated on the top of the dust layer (Haywood et al., 2008).  
21 However, during the boreal summer, biomass burning mainly occurs in South Africa,  
22 where the air circulations transport smoke plumes toward the South-East Atlantic off-  
23 coasts of Namibia and Angola (Zuidema et al., 2016; Cochrane et al., 2022). To study the

1 effects of Saharan dust aerosols on AEWs with avoiding the major impact of smoke  
2 transport from biomass burning in South Africa, we focus our study on the region above  
3  $5^{\circ}$  N latitude in West Africa and the eastern Atlantic Ocean in boreal Summer, where the  
4 contribution of aerosols from biomass burning is less than 15% by mass over this region  
5 (Matsuki et al., 2010). This study focuses on boreal summer season, because during this  
6 season, the amplitude of AEWs peaks (e.g., Roundy and Frank, 2004), and Saharan dust  
7 storms are active with less simultaneous transport of smoke from South Africa biomass  
8 burning.

9         While previous studies showed the impacts of dust aerosols on climate (Ming and  
10 Ramaswamy, 2011; Hosseinpour and Wilcox, 2014; Chen et al., 2021; Liang et al., 2021;  
11 Grogan et al., 2022), hydrological cycle (Konare et al., 2005; Kim et al., 2010; Bercos-  
12 Hickey et al., 2020) and cloud properties (Weinzierl et al., 2017; Haarig et al., 2019),  
13 these elements of the climate system in this region exhibit strong variability due to AEWs.  
14 To understand the details of interactions between dust aerosols and climate over the  
15 Atlantic Ocean, it is essential to understand how the evolution of AEWs is determined by  
16 both diabatic heating, as well as exchanges of eddy kinetic energy (EKE) within the jet-  
17 wave system and how dust may contribute to the energy driving AEWs. Toward this goal,  
18 we apply eddy energetic concepts to further analyze the relationships between dust and  
19 the AEJ-AEWs system to gain insight into the impacts of the dust aerosol radiative effects  
20 on the development of AEWs and the distribution of kinetic energy from the source of  
21 instability (i.e., AEJ). Section 2 summarizes the data and methodology. Section 3  
22 discusses the summary of results: the climatology and variability of the AEJ-AEWs  
23 system from an energy point of view (3.1), climatology and variability of Saharan dust

1 aerosols across West Africa and the eastern tropical Atlantic Ocean (3.2), and the impacts  
2 of dust on the AEJ-AEWs system (3.3). Conclusions are presented in Section 4.

3

## 4 **2 Data and methodology**

5 This study focuses on the relationships of Saharan dust aerosols and AEWs in  
6 boreal summer, because during this season, the amplitude of the AEW peaks (e.g., Roundy  
7 and Frank, 2004). We used a 22-year time series of NASA's satellite observations and  
8 reanalysis for the boreal summer seasons from June to August (JJA) 2000-2021 to calculate  
9 the variability of energy components of the system comprising the AEJ, the AEWs, and  
10 the aerosol radiative effect.

11

### 12 **2.1 MODIS and MERRA-2 data**

13 To study the climatology of West Africa and the eastern tropical Atlantic Ocean,  
14 the successor to the Modern Era Retrospective-analysis reanalysis (MERRA; Rienecker et  
15 al., 2008; 2011), the 3-hourly MERRA-2 (Randles et al., 1980, 2017; Buchard et al., 1980;  
16 Gelaro et al., 2017) were used to provide more reliable assessments of climatic and  
17 meteorological variables from 1980 to the present. The MERRA-2 reanalysis has a 3-  
18 hourly temporal resolution and a spatial resolution of  $0.5^\circ$  latitude by  $0.625^\circ$  longitude with  
19 72 vertical levels, extending from the surface up to 0.01-hPa.

20 We used the MERRA-2 atmospheric radiative effect that is broad band shortwave  
21 flux across the visible spectrum to study aerosol radiative effect as described in Section  
22 2.2, as well as the meteorological variables, including wind components, temperature,  
23 pressure and humidity from the 3-hourly MERRA-2 reanalysis for the boreal summer (JJA)

1 from 2000 to 2021, to calculate the eddy energetic terms of the AEW-AEJ system as  
2 described in Section 2.3.

3 The reason for choosing the MERRA-2 analysis for this study is as follows: An  
4 essential aspect of MERRA-2 is the assimilation of bias-corrected aerosol optical depth  
5 (AOD) from the various ground- and space-based remote sensing platforms (e.g., Randles  
6 et al., 2017). In particular, AOD is simulated in MERRA-2 with a radiatively coupled  
7 version of the Goddard Chemistry, Aerosol, Radiation, and Transport (GOCART; Colarco  
8 et al., 2010) aerosol model. In this manner, the MERRA-2 system provides an estimate of  
9 the atmosphere state historically from the present day back to 1980. It is important to note  
10 that the dust and the circulation are fully coupled in MERRA-2. Using such an empirical  
11 tool, it is not possible to directly compare a complete representation of the circulation  
12 without dust to the circulation with dust. However, the benefit of using MERRA-2 is that  
13 it offers a more realistic representation of the circulation than an unconstrained model  
14 because of the data assimilation. It is our intention with this study to evaluate the empirical  
15 relationships between the dust radiative effect and the energetics of AEWs in a reanalysis  
16 constrained by observations, which can be compared with the results of a follow-on  
17 examination of a controlled experiment in an unconstrained atmospheric general  
18 circulation model comparing simulations with dust radiative effects to simulations without  
19 dust radiative effects.

20 To evaluate the MERRA-2 reanalysis with satellite observations, we used the  
21 entire record of the daily AOD (level 3) from two independent algorithms and well-  
22 calibrated sensors: (I) the 550-nm Moderate Resolution Imaging Spectro-radiometer dark-  
23 target retrieval (MODIS, MOD08\_D3; Remer et al., 2021 with a 1° spatial resolution on

1 Terra since 2000 for the dust domains over the Atlantic Ocean, and (II) the 470-nm Deep  
 2 Blue (Sayer et al., 2019; Hsu et al., 2019) retrievals of MODIS AOD available with a 1°  
 3 spatial resolutions for the dust source regions over the land in boreal summer (JJA, 2000-  
 4 2021). The summary of the information about MODIS and MERRA-2 data product name,  
 5 variables, spatial and temporal resolutions are provided in Table 1.

6

## 7 **2.2 Aerosol radiative effect in the atmosphere**

8 We used the components of aerosol radiative effect at the surface and top of the  
 9 atmosphere (TOA) from the 3-hourly MERRA-2 reanalysis datasets to calculate the  
 10 radiative effect of dust in the atmosphere (i.e., TOA minus surface) as follows:

$$11 \quad F_{aerosol} = (SWF_{TOA_{tot}} - SWF_{TOA_{clean}}) - (SWF_{sfc_{tot}} - SWF_{sfc_{clean}}) \quad \text{Eq. (1)}$$

12 where  $SWF_{TOA_{tot}}$  refers to the net downward shortwave radiation flux at the TOA,  
 13  $SWF_{TOA_{clean}}$  is the net downward shortwave flux at TOA under clean-sky condition,  
 14  $SWF_{sfc_{tot}}$  is the net downward shortwave flux at the surface, and  $SWF_{sfc_{clean}}$  is net  
 15 downward shortwave flux at the surface under clean-sky condition.

16 To show the variability of dust, the time-longitude Hovmöller diagrams of daily  
 17 anomalies of aerosol radiative effect are provided to represent the dust transport within  
 18 SAL across the tropical Atlantic Ocean. The daily values of radiative effect are calculated  
 19 by time averaging the 3-hourly data. The daily anomalies of radiative effect were calculated  
 20 with respect to the seasonal time-average of radiative effect for each year. These anomalies  
 21 were latitudinally averaged over the latitudes of dust domains, 12-22° N.

1 To investigate the relationship between dust and the AEJ-AEWs system over the  
 2 Atlantic Ocean, we focused on the dust variability over the ocean; therefore, we consider  
 3 the location of the SAL over the tropical Atlantic Ocean, the so-called OSAL domain,  
 4 where dust is significant from  $-28^{\circ}$  to  $-16^{\circ}$  E Longitude and from  $12^{\circ}$  to  $22^{\circ}$  N latitude in  
 5 the climatology of boreal summer seasons.

### 6 **2.3 Energetics of the AEJ-AEWs system**

7 We used MERRA-2 meteorological variables as described in Section 2.1, to  
 8 calculate the eddy energetic terms associated with the distribution of kinetic energy across  
 9 the AEJ-AEWs system for the boreal summer from 2000 to 2021. While the MERRA-2  
 10 data is 3 hourly, we averaged them for each day to be consistent with the daily temporal  
 11 resolution of MODIS AOD data. We provided daily MERRA-2 data to apply them for the  
 12 calculation of the eddy energetics terms.

13 From an energy point of view, the kinematics of the atmosphere is a combination  
 14 of mean kinetic energy (MKE) of the background mean flow and eddy kinetic energy  
 15 (EKE) representing transient eddies (Lorenz, 1954). The MKE associated with the AEJ is  
 16 calculated as below, where  $u$  and  $v$  are horizontal components of wind and bar represents  
 17 the time-averaged over the long-term daily time series of the wind components:

$$18 \quad MKE = \frac{1}{2}(\overline{u^2} + \overline{v^2}) \quad \text{Eq. (2)}$$

19 To detect the 2-6 day and 6-11 day variations associated with the AEWs, we used  
 20 the methodology following Wu et al. (2013). While many studies have focused exclusively  
 21 on 2-6 day period AEWs, several studies have found evidence that AEWs exist on two  
 22 distinct time scales of 2-6 and 6-11 day periods, as the structure of the AEWs differs

1 substantially between these two different time windows (Mekonnen et al. 2006; Wu et al.,  
 2 2013). The time-filtering method described below was applied to decompose EKE of the  
 3 AEWs at different time-scale: 2-6 day and 6-11 day filtered variations.

4 We provide the daily times series of wind components by time averaging over the  
 5 3-hourly MERRA-2 datasets. We further used the Lanczos bandpass filtering techniques  
 6 described in Duchon's (1979) study to filter the 2-6 and 6-11 day disturbances from the  
 7 daily time series of the zonal and meridional components of wind ( $u, v$ ). The daily  
 8 anomalies ( $u', v'$ ) of wind components ( $u, v$ ) were calculated for each boreal summer season  
 9 with respect to the average of that season ( $u' = u - \bar{u}$  and  $v' = v - \bar{v}$ ; primes indicate  
 10 daily anomalies, and bars show seasonal averages). Finally, EKE was calculated as the  
 11 average of the variances of  $u$  and  $v$  shown as follows:

$$12 \quad EKE = 1/2 \left( \overline{u'^2} + \overline{v'^2} \right) \quad \text{Eq. (3)}$$

13 The bars indicate the average over the entire JJA, 2000-2021, and the primed quantities  
 14 denote the deviation of wind components from the time-mean (daily anomalies) described  
 15 above.

16 Baroclinic conversion (BCC) is one of the most important components in the eddy  
 17 energy budget to distribute transient energy from the upstream baroclinic source across the  
 18 storm tracks downstream of the jetstream (e.g., Orlanski and Katzfey, 1991; and Chang et  
 19 al., 2002). The initiation of and the growth of the waves are significantly related to BCC,  
 20 where the transient eddies extract energy from the mean-flow through BCC (e.g., Plumb,  
 21 1986). Following the approach described in Chang et al. (2002) study, we calculated the  
 22 BCC term as below:

$$1 \quad \quad \quad BCC = -\overline{\omega' \alpha'} \quad \quad \quad \text{Eq. (4)}$$

2 where  $\omega$  is the rate of pressure ( $\omega = \frac{dp}{dt}$ ) and  $\alpha$  is a scale to estimate the changes in the  
 3 vertical profile of the gradient of geopotential height ( $\alpha = -\frac{\partial \phi}{\partial p}$ ). We investigate BCC to  
 4 identify the locations favorable for developing EKE in the AEJ-AEWs.

5

## 6 **2.4 Composite analysis**

7 The composite analyses for 2-6-day and 6-11-day variations of the eddy energetics  
 8 of the AEWs were conducted for the boreal summer seasons of 22 years, 2000-2021.  
 9 Composite EKE was calculated by subtracting the EKE values associated with the lower-  
 10 quartile radiative effect of dust from those EKE values associated with upper-quartile  
 11 aerosol radiative effect. We find the upper- and lower-quartile aerosol radiative effect  
 12 offshore, where the dust load is significant over the OSAL domain (rectangle in Figure 2a).  
 13 To determine the upper- and lower-quartile of aerosol effect, the aerosol effect over the  
 14 OSAL box is averaged at each time to create a time series of OSAL aerosol effect. The  
 15 daily time series of aerosol radiative effect of the grid points were spatially averaged over  
 16 the OSAL domain, which provided one single value of aerosol radiative effect for each  
 17 individual day in the long-term time series over the dust domain. For averaging over the  
 18 OSAL domain, area-weighted average is applied since the area of grid cells are not the  
 19 same. These time series of aerosol radiative effect were used to select the days of the upper  
 20 quartile and the lower quartile aerosol radiative effect for the summer season of each year.  
 21 Hence, we selected 23 days of the highest aerosol concentration (upper-quartile) and 23  
 22 days of the lowest aerosol concentration (lower-quartile) over each domain during boreal

1 summer of each year. From a climatology point of view, we used the upper quartile and  
2 lower quartile of dust over 22 years of data, such that there are 506 data points to represent  
3 the days with high values of dust concentration and 506 days with low values of dust over  
4 each domain of study.

5 Composite EKE is provided for each grid point by subtracting the EKE values  
6 corresponding to the upper-quartile dust days from those of the lower-quartile dust days.  
7 Using the method explained above, the composite of the variance of zonal wind ( $\overline{u'^2}$ ), the  
8 variance of meridional wind ( $\overline{v'^2}$ ), and the transient momentum fluxes ( $\overline{u'v'}$ ) were also  
9 calculated for boreal summer seasons, JJA, 2000-2001 (Figure 1).

## 10 **2.5 Time-lag analysis**

11 The time-lag analyses were conducted over each domain of study based on the  
12 following processes. Using the same methodology explained above (Section 2.4.), we used  
13 the time series of aerosol radiative effect spatially averaged over the dust domain to select  
14 the days in the upper quartile and the lower quartile aerosol radiative effect, such that there  
15 are 506 data points to represent the days with high values of dust concentration and 506  
16 days with low values of dust concentration over each domain. For every 506 days of high  
17 dust concentration, we studied the time series for five days before and five days after the  
18 event to investigate the evolution of each individual dust storm. For each time series, we  
19 assigned each day of 506 days as follows:  $T = 0$  for the dust-peak,  $T = 1$  for one day after  
20 the dust-peak,  $T = -1$  for one day before the peak of dust, and continue this for five days  
21 before and after every 506 days. We used each of these time series for 22 years and average  
22 dust radiative effect individually for  $T = 0$ ,  $T = +/- 1$ ,  $T = +/- 2$ ,  $T = +/- 3$ ,  $T = +/- 4$ , and

1 T= +/- 5 to gain insight into the climatology of dust evolution five days before and five  
2 days after dust peaks over each domain. We repeated the steps explained above for the 506  
3 data points of dust in the lower quartile to provide the long-term time series of low aerosol  
4 radiative effect over the dust domain. Finally, by subtracting the time series of the lower  
5 quartile from the upper quartile radiative effect, we provide the composite of dust over  
6 each domain to investigate the highest variability of dust (as T = 0, Figure 5) and its  
7 evolution five days before and after over dust domain. Using the same methodology, we  
8 analyzed the wave activity that coincides with the upper quartile (and lower quartile)  
9 aerosol radiative effect to investigate a possible time-lag between the dust and the  
10 development of kinetic energy over the northern and southern track of the AEWs. The  
11 domains selected to investigate wave activity are shown in Table 2.

12

### 13 **3 Summary of the results**

#### 14 **3.1 AEJ-AEWs system from an energy perspective**

15 Traditional studies have used the mid-tropospheric trough and ridge from unfiltered  
16 wind fields to diagnose the AEWs. In this manner, the AEWs trough was identified where  
17 the meridional wind at the vertical level of the AEJ is equal to zero, indicating that the wind  
18 shifts from northerlies to southerlies (Diedhiou et al., 1999). The existence of two distinct  
19 tracks of the AEWs: the northern and southern tracks (e.g., Diedhiou et al., 1999; Nitta and  
20 Takayabu, 1985; Reed et al., 1988; Wu et al., 2013) have been identified by examining the  
21 vorticity structure of the AEWs (e.g., Carlson 1969 a&b; Thorncroft and Hodges, 2001;  
22 Hopsch et al., 2007) and applying the reversal of the meridional gradient of potential  
23 vorticity (e.g., Norquist et al., 1977; Pytharoulis and Thorncroft, 1999; Kiladis et al., 2006).

1 However, these methods are limited because of the overlapping scale of AEWs with other  
2 phenomena and the significant amount of manual intervention required to differentiate  
3 between synoptic-scale AEW trough axes and localized circulation centers. As a solution  
4 to this problem, here we applied the eddy energy budget to diagnose the growth and  
5 evolution of the AEWs.

6 Hosseinpour and Wilcox (2014) showed that the axis of the AEJ core resides at  
7 about 600-hPa during the boreal summer; thus, here we present the results for 600-hPa,  
8 where the activity of the AEJ-AEWs system is maximized. Figure 1a shows the mid-level  
9 AEJ in the climatology of boreal summer. The core of the jet is zonally located from 20°  
10 E to 30° W between the Sahel and the Sahara and spans from Africa toward the Atlantic  
11 Ocean, where the jet axis is located at ~15° N latitude. The closed contours in Figure 1b-c  
12 represent the MKE of the AEJ. The MKE peaks at ~12-18° N, collocated with the core of  
13 the AEJ (Figure 1a). The long-term mean of the mid-level EKE for the 2-6-day (warm  
14 shades in Figure 1b) and 6-11-day (warm shades in Figure 1c) bandpass filtered EKE  
15 represents the kinetic energy of two distinct categories of the AEWs: The 2-6-day bandpass  
16 EKE peaks offshore, downstream and along the northern side of the jet core, while the 6-  
17 11-day bandpass EKE has a weaker signal over the northern side of the jet compared to 2-  
18 6-day EKE. The significant signal of the 2-6-day AEWs over the tropical Atlantic implies  
19 the significant contribution of 2-6-day transient eddies in transient disturbances over the  
20 Ocean.

21 In addition, both 2-6-day and 6-11-day bandpass EKE can develop at the higher  
22 latitudes above ~32° N toward the subtropics, which can be related to the impacts of the  
23 westerly Rossby waves of the subtropical storm track over North Africa. These are

1 consistent with the previous studies, showing that after leaving the West coast of Africa,  
2 the majority of AEWs either (1) penetrate the subtropical Atlantic Ocean via an interaction  
3 with an extratropical trough, or (2) develop further downstream and are involved in tropical  
4 cyclogenesis (Berry et al., 2007; Chen et al., 2008).

### 5 **3.1.1 Behaviors of transient eddies of the AEWs**

6 In this Section, we further investigate the characteristics of the AEWs. Figures 1d  
7 and 1e show the climatology of transient eddies. The variance of zonal wind ( $\overline{u'^2}$ )  
8 represents the zonal transient eddies (Figure 1d), which peak at  $\sim 6-12^\circ$  N and are elongated  
9 downstream along the southern edge of the AEJ from approximately  $15^\circ$  W to  $45^\circ$  W.  
10 Comparing this with Figure 1b shows that the increase of 2-6-day bandpass EKE  
11 downstream of the jet core corresponds to the 2-6-day zonal transient eddies, whereas the  
12 core of the 2-6-day EKE over the northern track AEWs at  $\sim 18-24^\circ$  N is related to the  
13 meridional wind variance ( $\overline{v'^2}$ ), which represents the 2-6-day meridional transient eddies  
14 (Figure 1e). These patterns suggest that transient eddies of the 2-6-day time-scale AEWs  
15 are elongated both zonally and meridionally.

16 Figure 1f gives further information about the structure and propagation of the 2-6-  
17 day eddies. The enhanced transient momentum flux ( $\overline{u'v'}$ ) of 2-6-day bandpass eddies over  
18 the northern and southern tracks of the AEWs indicates the orientation and the group  
19 velocity of the transient eddies relative to easterly mean-flow. The positive values of the  
20 transient momentum flux are dominant over the southern sides of the jet core, suggesting  
21 that the southern track transient eddies propagate with a NE-SW orientation, whereas the  
22 negative values of the transient momentum flux over the northern track suggest the NW-

1 SE orientation of transient eddies relative to the mean-flow. The relatively tilted  
2 orientations of the eddies over the northern and southern track, fanning out or diverging  
3 downstream of the jet core, are signatures of the so-called downstream development, where  
4 transient eddy activity associated with 2-6-day AEWs is enhanced. The magnitude of the  
5 transient momentum flux shows the 2-6-day eddies over the northern and southern tracks  
6 of the AEWs propagate faster relative to the easterly mean-flow, whereas the values of  
7 transient momentum flux are negligible along the AEJ axis where the mean-flow is strong.  
8 To further investigate the behavior of the 2-6-day eddies, we discuss the baroclinic and  
9 barotropic instability of the waves in the following Section.

### 10 **3.1.2 Baroclinic instability of the AEJ-AEWs system**

11 Baroclinic instability is the dynamic cause for synoptic-scale storms as a result of  
12 vertical shear of the zonal wind, corresponding to meridional temperature gradients based  
13 on the thermal wind balance (e.g., Charney, 1947; Eady, 1949). Meridional temperature  
14 gradient is also proportional to the available potential energy in baroclinic instability  
15 mechanism (Hoskins et al., 1983; Grotjahn, 2003). Baroclinic zones are defined as the  
16 favored areas for strengthening and weakening of systems, where eddies extract available  
17 potential energy from the mean-flow and convert the eddy available potential energy to  
18 EKE through baroclinic conversion (BCC) of energy (Chang et al., 2002; Orlandi and  
19 Katzfey, 1991). The changes in meridional temperature gradient also contribute to the  
20 changes in EKE of the waves (e.g., Coumou et al., J., 2015; Gertler and O’Gorman, 2019).

21 Previous studies showed that  $\overline{u'v'}$  is an indicator of baroclinic instability at the exit  
22 region of the jet (e.g., Hoskins et al., 1983). Figure 1f represents the presence of baroclinic

1 instability ( $\overline{u'v'}$ ) at the northern and southern tracks of the waves downstream of the jet  
2 core, showing the development of the 2-6-day transient eddy activity downstream of the  
3 AEJ corresponds to the presence of baroclinic instability in the region where eddies can  
4 extract energy from the easterly mean-flow through baroclinic conversion (as described in  
5 the following Section). These suggest that the northern and southern tracks of the AEWs  
6 are favorable areas for the potential growth of baroclinic transient eddies as the variations  
7 in baroclinic instability tend to extract energy from the jet and convert it to eddy energy  
8 downstream of the AEJ, where the jet weakens.

9         We further investigated the conversion of energy through BCC by studying the  
10 fraction of the total variance of BCC (Figure 1g) attributable to variations on less than 11-  
11 day time scales, which includes both the 2-6-day AEWs and 6-11-day AEWs. Figure 1g  
12 shows that these variations account for a significant fraction of BCC variations over land,  
13 where the AEJ core resides (Figure 1a), and this high fraction of BCC variance extends  
14 offshore over the northern and southern sides of the AEJ. This is consistent with the  
15 discussion above, suggesting the eddy activity occurs at the north and south sides of the  
16 AEJ (Figure 1f), where the transient zonal and meridional eddies (Figures 1d-e) extract  
17 energy from the MKE (contours in Figure 1b-c) and convert it to EKE (Figure 1b-c)  
18 through BCC.

19         In the next Section, we investigated the relationships between the African aerosols  
20 and the AEWs. Studying the time series of EKE and dust anomalies shows a similarity  
21 between the variability of dust radiative effect and the changes of the 2-6-day EKE over  
22 the northern and southern tracks of the AEWs (Figures S1 and S2), suggesting a possible  
23 impact of dust diabatic heating on the enhancement of the kinetic energy of the AEWs.

1 Such a relationship between dust and AEWs is also seen over each individual JJA (Figures  
2 S1, S2, and S3). We explore Saharan dust variability (Section 3.2) and then investigate the  
3 possible impacts of aerosol radiative effect of dust concentration on the energy of AEWs  
4 (Section 3.3).

5

### 6 **3.2 Saharan dust plumes- climatology and variability**

7 The significant dust transport from the Saharan desert across the Atlantic Ocean is  
8 seen in the long-term mean of Saharan dust optical thickness and radiative effect vertically  
9 integrated over the troposphere during boreal summer (Figures 2a-c). The inherent  
10 limitation of MODIS satellite observations is the lack of AOD data over the highly-  
11 reflective desert regions (Figure 2a) and the Deep Blue AOD over the Ocean (Figure 2b).  
12 Because of that, based on Eq. (1) we calculated aerosol shortwave radiative effect from the  
13 MERRA-2 reanalysis as a complementary component (Figure 2c) to the satellite  
14 observations. This was further examined by the scatter plots of MODIS AOD over the  
15 Ocean (Figure 2d) and Deep Blue over the land (Figure 2e) with respect to MERRA-2  
16 radiative effect, where daily data points were averaged over the oceanic and land dust  
17 domains (rectangle in Figures 2a and 2b, respectively). This shows that MERRA-2  
18 reanalysis is highly correlated with MODIS observations with R-values of 0.83 and 0.62,  
19 respectively, and statistically significant with P-values less than 0.05. From a climatology  
20 point of view, the maximum value of dust heating the atmosphere is approximately  $35 \text{ Wm}^{-2}$ ,  
21 localized over the western and central Saharan Desert in JJA, 2000-2021 (Figure 2c). In  
22 addition, the radiative effect efficiency for atmospheric heating by Saharan dust inferred

1 from these scatter plots (Figures 2d-e) is roughly  $20 \text{ Wm}^{-2}$  per unit AOD over the ocean  
2 and  $35 \text{ Wm}^{-2}$  per unit AOD over land.

3 We investigated dust variability by studying the changes in daily radiative effect  
4 during dust transport across the tropical Atlantic Ocean. The longitude-time Hovmöller  
5 diagrams of daily aerosol radiative effect anomalies are provided for each summer from  
6 2000 to 2021 (Figure 3). The aerosol radiative effect is meridionally averaged over the  
7 SAL,  $12\text{-}22^\circ\text{N}$ , where the dust concentration is high. The positive and negative anomalies  
8 show the increase and decrease of aerosol radiative effect within the SAL as dust  
9 propagates in transient dust plumes across the tropical Atlantic Ocean. Figure 3 shows that,  
10 on average, dust transport may reach the Caribbean Sea in less than 11 days. To investigate  
11 the climatology of this, the fraction of total variance of dust radiative effect was calculated  
12 for less than 11-day and more than 11-day of dust variations during boreal summer seasons,  
13 2000-2021 (Figures 2f-g). The variations of aerosol radiative effect for less than 11-day  
14 timescale variations are significant over West Africa and the eastern tropical Atlantic  
15 Ocean and account for up to 70-80% of the total variance of aerosol radiative effect over  
16 these regions. In contrast, the variations of dust radiative effect longer than 11-day are a  
17 more significant fraction of the variance upstream, mainly over the dust sources in the  
18 Saharan Desert.

19 We conducted similar Hovmöller analyses as above, but for MODIS observations  
20 as a check on the variability of dust radiative effect in the MERRA-2 reanalysis and found  
21 that the results from MERRA-2 reanalysis were consistent with the MODIS AOD (Figure  
22 S3). Analyzing the dust storm events from 2000 to 2021 suggests a possible relationship  
23 between the dust transport and the variations of the AEJ-AEWs system. Our hypothesis is

1 that the variations of dust across the ocean during Saharan dust storms contribute to the  
2 growth of the waves over the ocean through diabatic heating from dust radiative effect. To  
3 investigate this, we focus on the dust over the oceanic domain (i.e., OSAL; rectangle in  
4 Figure 2a). The steps to study this are described in the following sections.

### 5 **3.3 Impacts of dust radiative effect on the energy of the AEWs**

6 Previous studies have discussed the dynamics of the AEWs as summarized in the  
7 introductory Section; however, the relationships between dust radiative effect and the  
8 kinetic energy of the AEWs are still unexplored. In this Section, we investigate the  
9 relationships between dust radiative effect of the atmosphere (TOA minus surface) and the  
10 kinetic energy of the AEWs during the boreal summer from 2000 to 2021.

#### 11 **3.3.1 Composite analysis of eddy energetics with respect to dust variability**

12 The composite analyses were conducted for the boreal summer seasons of 22 years.  
13 The composite of the 2-6-day and 6-11-day filtered EKE (Figures 4a and 4b, respectively)  
14 are based on the EKE values for the times that correspond to the upper-quartile dust  
15 radiative effect in the OSAL region (rectangle in Figure 2a) minus the EKE values of the  
16 times correspond to the lower-quartile dust radiative effect. The steps to calculate  
17 composite diagrams are explained in Section 2.

18 The positive anomalies in Figure 4a show the increase of the 2-6-day EKE at the  
19 southern track ( $\sim 6-12^\circ\text{N}$ ) of the AEWs and further downstream over the northern track ( $\sim$   
20  $18-24^\circ\text{N}$ ) coincide with the enhanced radiative effect of dust over the offshore region. The  
21 dipole pattern of the positive and negative anomalies may also imply a possible southward

1 shift of the 2-6-day EKE at the southern edge of the AEJ during high dust concentrations.  
2 A similar dipole pattern can also be seen in Figure 4c.

3 Figure 4c shows the increase of the zonally elongated 2-6-day eddies at the southern  
4 edge of the jet, which suggests that the strengthening of the 2-6-day zonal transient eddies  
5 may lead to the amplification of EKE (Figure 4a) over the southern track of the waves  
6 during dust events when aerosol radiative effect is significant offshore. Meanwhile, the  
7 increase of the meridional elongated transient eddies (Figure 4d) coincides with the high  
8 concentrations of dust. Comparing this with Figure 4a suggests that during high dust  
9 concentration in OSAL, the amplification of the 2-6-day EKE further downstream in the  
10 northern track of the AEWs corresponds to the enhanced meridional elongated transient  
11 eddies. While the positive anomalies of 2-6-day  $\overline{u'v'}$  (Figure 4e) is a weaker signal at the  
12 northern and southern tracks of the waves, it is still statistically significant, which shows  
13 that the enhancement of the baroclinic instability over the northern and southern tracks of  
14 the AEWs occurs during high aerosol radiative effect in OSAL.

15 The negative composite along the AEJ axis at about 12-18°N (Figure 4) can be  
16 related to the fact that the 2-6-day and 6-11-day EKE are not significant along the AEJ  
17 axis, where the MKE and the horizontal shear of mean-flow are strong (Figure 1a-b-c). As  
18 described in Section 3.1., the growth of transient eddies is more likely over the south and  
19 north side of the jet, where the jet weakens and thus offers a greater chance for the  
20 development of baroclinic AEWs (Figure 1f-g). While the negative anomaly may seem  
21 like a reduction of eddy activity along the AEJ axis simultaneously at the time of dust  
22 enhancement, in the next Section (3.3.2), we have evidence that the amplification of 2-6-

1 day EKE along the AEJ axis starts on average two days after the peak of dust offshore  
2 (Figures 5 d-e).

3 We conducted the same composite analysis using MODIS AOD, which shows that  
4 the results are consistent whether the MERRA-2 radiative effect metric or the MODIS  
5 AOD data are applied (Figure S4). Overall, these composite analyses suggest a mechanistic  
6 relationship between the kinetic energy of the AEJ-AEWs system over the ocean and  
7 aerosol radiative effect during dust outbreaks in summer. The enhanced dust offshore  
8 coincides with the strengthening of the baroclinic instability and amplification of the 2-6-  
9 day AEWs downstream, where the jet weakens and gives a chance to strengthen the  
10 propagation of the zonally and meridionally elongated transient eddies over the southern  
11 and northern tracks of the waves, respectively. In the following Section, we study a possible  
12 time lag between the occurrence of dust storms and the changes in the activity of the waves  
13 over various domains.

14

### 15 **3.3.2 Time-lag between dust outbreaks and development of the AEWs**

16 In this Section, we investigate a possible lag between the changes of the EKE with  
17 respect to the variability of dust radiative effect over the OSAL. We divide the northern  
18 track waves ( $18^{\circ}$  to  $24^{\circ}$  N) and southern track ( $6^{\circ}$  to  $12^{\circ}$  N) of the AEWs into two separate  
19 regions: Eastern Atlantic ( $-15^{\circ}$  to  $-30^{\circ}$ E) and Central Atlantic ( $-30^{\circ}$  to  $-45^{\circ}$ E). We also  
20 study the possible lag between dust in OSAL and the eddy activity downstream of the jet  
21 core ( $12^{\circ}$  to  $18^{\circ}$ N) over the eastern and central Atlantic domains (Table 2). The time lag is  
22 investigated between composite EKE over each wave domain with respect to composite

1 dust radiative effect in OSAL. The methodology for calculating time lag is described in  
2 Section 2.

3 The variability of dust radiative effect (i.e., composite for daily upper quartile  
4 aerosol radiative effect minus daily lower quartile aerosol radiative effect) in Figure 5a  
5 represents the daily variations of radiative effect five days before and after the peak of dust  
6 in the OSAL region for the 22 years of boreal summer seasons. This shows the variability  
7 of dust radiative effect associated with the dust outbreaks over the OSAL region is  
8 significant for about six days, as it starts three days before ( $T = -3$ ) and ends three days  
9 after ( $T = +3$ ) the peak of dust ( $T = 0$ ), which is consistent with the timescale of the 2-6-  
10 day AEWs. Similar analyses are conducted using the upper quartile radiative effect only to  
11 investigate such relationships for the days with high dust concentration (Figure S5). The  
12 results are consistent with the patterns shown in Figure 5.

13 Figures 5b represents the time evolution and changes in 2-6-day EKE of the  
14 northern track AEWs further downstream over the eastern Atlantic Ocean. The changes in  
15 EKE seem negligible at  $T < 0$  before starting the high variations in dust in OSAL; however,  
16 the growth of EKE occurs on average at  $T = 0$ , coinciding with the peak of dust, and then  
17 continues growing and reaches its maximum about three days ( $T = +3$ ) after the peak of  
18 dust variations. In contrast, although a slight decrease and increase of EKE are seen  
19 respectively before and after dust peaks, the variations of the northern track EKE over the  
20 eastern Atlantic (Figure 5c) seem weaker compared to those further downstream.  
21 Comparing Figure 5b with the composite analysis in Figure 4a suggests that the  
22 enhancement of the northern track 2-6-day EKE, further downstream over the central

1 Atlantic, coincides with the peak of dust and is even more significant on average three days  
2 after dust peaks in OSAL.

3 The negative variations of the EKE in Figures 5d and 5e at  $T = 0$  are consistent with  
4 the negative composite of the EKE along the AEJ axis in Figure 4. This means that the  
5 decay of EKE along the jet axis over the Central Atlantic (Figure 5d) is initiated before  
6 dust activity; however, the rapid growth of EKE starts on average two days ( $T = +2$ ) after  
7 the peak of dust and is maximized about three to four days ( $T \sim +3$  to  $+4$ ) after the peak of  
8 dust in OSAL. A similar, but weaker pattern, is seen across the jet axis over the eastern  
9 Atlantic (Figure 5e).

10 Figures 5f and 5g show that the changes in EKE are maintained positive before and  
11 after dust activity. Comparing Figure 5f with Figure 5a suggests that the activity of both  
12 dust plumes in OSAL and the southern EKE anomalies over the central Atlantic is initiated  
13 about three days ( $T = -3$ ) before dust peaks, and then amplification of EKE continues and  
14 reaches its maximum on average two days ( $T = +2$ ) after dust peaks.

15 Over the eastern tropical Atlantic (Figure 5g), the EKE variations seem negligible  
16 during dust storms. The weaker signal of the southern track EKE variations over the eastern  
17 Atlantic can be explained by the dynamic and energy of the AEJ-AEWs system (Figure 1),  
18 as this is the region where the southern edge of the jet is dominant, and the MKE and  
19 conversion of energy to EKE through BCC are significant. This suggests that while the  
20 positive anomalies of EKE over this region coincide with the enhancement of dust in  
21 OSAL, the influence of dust radiative effect on changes in EKE could be weak  
22 quantitatively compared to the amount of energy exchange between the components of the  
23 AEJ-AEWs system at the southern edge of the jet core.

1           Comparing Figures 5b, 5d, and 5f reveals evidence of the mechanistic relationship  
2 between variability of dust radiative effect offshore and the changes in the 2-6-day EKE  
3 further downstream over the Central tropical Atlantic, where the easterly flow weakens at  
4 the exit region of the jet over the central Atlantic. On average, the peak of dust load in  
5 OSAL occurs a few days before the amplification of the EKE downstream of the AEJ; a  
6 similar pattern is also seen with a weaker signal over the eastern tropical Atlantic. The lag  
7 analyses, summarized in Table 3, suggest that the peak of dust aerosols loading offshore  
8 over the OSAL region precedes the amplification of EKE further downstream of the AEJ  
9 over the central Atlantic Ocean. This evidence is consistent with our hypothesis on the  
10 influence of dust radiative effect, fueling the EKE of the 2-6-day AEWs downstream of the  
11 AEJ over the tropical Atlantic Ocean, where tropical cyclogenesis and hurricane activity  
12 occur. We further investigated our analyses by selecting various dust domains (e.g., 12° to  
13 22°N and -38° to -28°E, shown in Figure S6) and showed that our findings are consistent  
14 regardless of the location of dust domain in SAL across the tropical Atlantic Ocean.

15

## 16 **4     Conclusions**

17           While previous studies showed the relationship between dust transport and AEJ and  
18 AEWs across the Atlantic Ocean (Perry et al., 1997; Liu et al., 2008; Francis et al., 2020;  
19 Francis et al., 2021) the feedback of dust to AEJ-AEW is not well understood. A few recent  
20 studies showed that dust affects the atmospheric dynamics of the Atlantic Ocean by  
21 enhancing AEJ and AEW strength (e.g., Bercos-Hickey et al., 2017; Grogan et al., 2016).  
22 However, the mechanisms of such effects are still open questions.

1           This study shows mechanistic relationships between the radiative effect of dust  
2 aerosols in SAL and the kinetic energy of the AEWs across the tropical Atlantic Ocean  
3 using 22 years of daily satellite observations, as well as reanalysis data based on satellite  
4 assimilation. Dust plumes across the Atlantic are not merely transported by AEJ-AEWs  
5 system but also contribute to increasing the kinetic energy of the baroclinic AEWs through  
6 diabatic heating. The enhanced dust contributes to an increase in meridional temperature  
7 gradients (Hosseinpour and Wilcox, 2014), which leads to an increase in baroclinicity and  
8 amplification of the EKE of the AEWs.

9           The efficiency of dust radiative effect in the atmosphere is a heating of roughly 20  
10  $\text{Wm}^{-2}$  per unit AOD over the ocean and  $35 \text{ Wm}^{-2}$  per unit AOD over land. This agrees with  
11 in-situ measurements (Soupiona et al., 2020) and regional climate modeling (Saidou  
12 Chaibou et al., 2020) of Saharan dust radiative effect. This radiative effect of dust aerosols  
13 in the SAL contributes to the diabatic heating of the atmosphere in the regions  
14 (Hosseinpour and Wilcox, 2014) where the increase in temperature gradients leads to the  
15 growth of baroclinic waves through the conversion of energy to EKE in the AEJ-AEWs  
16 system. Outbreaks of high dust concentrations in the SAL coincide with the growth of the  
17 meridionally elongated 2-6-day transient eddies over the northern track of AEWs (~18-  
18  $24^{\circ}\text{N}$ ) and zonally elongated eddies over the southern track of AEWs (~6- $12^{\circ}\text{N}$ ). This leads  
19 to amplifying the EKE of the AEWs, particularly at the exit region of the AEJ, where the  
20 MKE and the horizontal shear of mean-flow are weakened. This offers the chance for  
21 downstream development of the AEWs, associated with enhanced dust. The dust-induced  
22 enhancement of AEW through a buoyancy source was shown by Grogan et al. (2016),  
23 albeit with a different methodology (i.e., analytical and regional modeling analyses). In

1 addition, our results agree with a case study of the Saharan dust event by a regional climate  
2 model (Bercos-Hickey et al., 2017) that showed that Saharan dust causes AEW to shift  
3 northward and expand westward.

4 The growth of the baroclinic transient eddies, and the corresponding EKE of the 2-  
5 6-day AEWs, is amplified at the exit region of the AEJ, on average, two to four days after  
6 the enhancement of dust upstream in the OSAL region. Our findings show that dust activity  
7 precedes the amplification of EKE, suggesting that the diabatic heating from dust radiative  
8 effect can fuel the development of the AEWs. This mechanistic impact of dust radiative  
9 effect onto AEW development is consistent across the tropical Atlantic Ocean.

10 This study further supports a hypothesis between dust radiative effect and transient  
11 wave dynamics that may be tested in sensitivity studies with dynamical climate models to  
12 explore further the cause and effect of such relationships. The data assimilation in  
13 MERRA-2 provides a realistic representation of circulation, while one caveat of using  
14 MERRA-2 alone is that it is not possible to compare a dust-free circulation to a dusty  
15 circulation. The empirical relationships apparent from this study will be examined in a  
16 follow-on study of atmospheric general circulation model simulations with and without the  
17 dust radiative effect to further explore the hypothesis linking dust radiative effects to AEW  
18 dynamics.

1 **Table 1** MODIS and MERRA-2 data information applied in this study

Dataset	Product Name	Variables	Spatial Resolution	Temporal Resolution	Data Reference
MODIS	MOD08_D3	550-nm AOD, Deep-blue AOD	1°×1°	daily	Platnick (2015)
MERRA-2	M2I6NPANA	U, V, T, H	0.5°×0.625°	3-hourly (averaged to daily)	GMAO (2015a)
	M2T1NXRAD	SWF <sub>TOA<sub>tot</sub></sub> , SWF <sub>TOA<sub>clean</sub></sub> , SWF <sub>sfc<sub>tot</sub></sub> , SWF <sub>sfc<sub>clean</sub></sub>	0.5°×0.625°	1-hourly (averaged to daily)	GMAO (2015b)
	M2I3NPASM	Omega	0.5°×0.625°	3-hourly (averaged to daily)	GMAO (2015c)

2

3 **Table 2** The coordinates of domains of transient changes across the tropical Atlantic

4 Ocean:

AEW domains		
Description	Central Atlantic	Eastern Atlantic
Northern track waves	18° to 24°N -45° to -30°E	18° to 24°N -30° to -15°E
Downstream of jet-axis	12° to 18°N -45° to -30°E	12° to 18°N -30° to -15°E
Southern track waves	6° to 12°N -45° to -30°E	6° to 12°N -30° to -15°E

5

6

- 1 **Table 3** Summary of lag analyses showing AEWs evolution before and after dust peaks in  
 2 OSAL:

<b>Downstream development of eddy activity – Central Atlantic</b>			
	<b>Before Dust-peak</b>	<b>Simultaneously at Dust-peak</b>	<b>After Dust-peak</b>
Northern track AEWs	T < 0 Negligible changes in EKE	T = 0 EKE starts increasing	T = +3 Max EKE
Along the AEJ axis	T < 0 Negligible changes in EKE	T = 0 Decrease of EKE	T = +2 EKE starts increasing  T ~ +3 to +4 Max EKE
Southern track AEWs	T = -3 EKE starts increasing	T = 0 Increase of EKE	T = +2 Max EKE

3

1

2 **Figure 1** (a) Long-term mean of 600-hPa wind speed ( $\text{m s}^{-1}$ ) from MERRA-2 reanalysis over JJA,  
 3 2000-2021. (b) Same as (a) but for 2-6-day bandpass filtered EKE ( $\text{m}^2 \text{s}^{-2}$ ) at 600-hPa. (c) Same as (b) but for  
 4 6-11-day bandpass filtered EKE. (d) Same as (b) but shows the 2-6-day variance of zonal wind,  $\overline{u'^2}$ , ( $\text{m}^2 \text{s}^{-2}$ ).  
 5 (e) Same as (b) but shows the 2-6-day variance of meridional wind,  $\overline{v'^2}$ , ( $\text{m}^2 \text{s}^{-2}$ ). (f) Same as (b) but for the  
 6 2-6-day filtered transient momentum fluxes,  $\overline{u'v'}$ , ( $\text{m}^2 \text{s}^{-2}$ ). (g) Fraction of less than the 11-day variance of  
 7 600-hPa Baroclinic Conversion (BCC) with respect to the total variance of BCC in JJA, 2000-2021.

8

4  
5

**Figure 3** Time-longitude Hovmöller diagrams of aerosol radiative effect daily anomalies ( $\text{Wm}^{-2}$ ) using the MERRA-2 reanalysis for all individual boreal summer seasons, JJA from 2000 to 2021, meridionally averaged ( $12\text{-}22^\circ \text{N}$ ) over the OSAL domain (rectangle in Figure 2a). Daily anomalies of aerosol radiative effect are calculated with respect to the seasonal time average of radiative effect for each year.

1  
 2 **Figure 4** (a) Composite 600-hPa 2-6-day filtered EKE ( $\text{m}^2\text{s}^{-2}$ ) values for the times corresponding to the upper  
 3 quartile aerosol radiative effect minus the EKE values of the times corresponding to the lower quartile aerosol  
 4 radiative effect over the OSAL domain (rectangle in Figure 2a). The calculations are conducted using the  
 5 MERRA-2 reanalysis for JJA, 2000-2021. (b) Same as (a) but for 6-11-day filtered EKE ( $\text{m}^2\text{s}^{-2}$ ). (c) same as  
 6 (a) but for the 2-6-day variance of zonal wind,  $\overline{u'^2}$ , ( $\text{m}^2\text{s}^{-2}$ ). (d) As in (a) but for 2-6-day the variance of  
 7 meridional wind,  $\overline{v'^2}$ , ( $\text{m}^2\text{s}^{-2}$ ). (e) Same as (a) but for the 2-6-day filtered momentum fluxes,  $\overline{u'v'}$ , ( $\text{m}^2\text{s}^{-2}$ ).

1 **Figure 5** (a) Daily time series of composite aerosol radiative effect for the days in the upper quartile minus  
2 those days in the lower quartile radiative effect, spatially averaged over the OSAL domain (rectangle in  
3 Figure 2a).  $T = 0$  is assigned for the days with the highest variability of aerosol radiative effect in the  
4 OSAL.  $T = +/- 1$ ,  $T = +/- 2$ ,  $T = +/- 3$ ,  $T = +/- 4$ , and  $T = +/- 5$  are assigned for five days before and five  
5 days after each individual dust event, averaged over for 22 years, JJA, 2000-2021. (b) Same as (a) but for  
6 the composite 2-6 day filtered EKE at 600-hPa, spatially averaged over the northern track AEWs in the  
7 central Atlantic ( $18^\circ$  to  $24^\circ\text{N}$ ,  $-45^\circ$  to  $-30^\circ\text{E}$ ). (c) Same as (b) but for the eastern Atlantic ( $18^\circ$  to  $24^\circ\text{N}$ ,  $-$   
8  $30^\circ$  to  $-15^\circ\text{E}$ ). (d) Same as (b) but spatially averaged over the domain, downstream of the AEJ in the central  
9 Atlantic ( $12^\circ$  to  $18^\circ\text{N}$ ,  $-45^\circ$  to  $-30^\circ\text{E}$ ). (e) same as (d) but for the eastern Atlantic ( $12^\circ$  to  $18^\circ\text{N}$ ,  $-30^\circ$  to  $-$   
10  $15^\circ\text{E}$ ). (f) same as (b) but spatially averaged over the southern track of the AEWs in the central Atlantic  
11 ( $6^\circ$  to  $12^\circ\text{N}$ ,  $-45^\circ$  to  $-30^\circ\text{E}$ ). (g) Same as (f) but for the eastern Atlantic ( $6^\circ$  to  $12^\circ\text{N}$ ,  $-30^\circ$  to  $-15^\circ\text{E}$ ). The  
12 domains of the wave activity are listed in Table 3.
