**Abstract.** The scattered seismic waves of fractured porous rock are strongly affected by the wave-induced fluid pressure diffusion effects between the compliant fractures and the stiffer embedding background. To include these poroelastic effects in seismic modeling, we develop a numerical scheme for discrete distributed large-scale fractures embedded in fluid-saturated porous rock. Using Coates and Schoenberg's local effective medium theory and Barbosa's dynamic linear slip model characterized by complex-valued and frequency-dependent fracture compliances, we derive the effective viscoelastic compliances in each spatial discretized cell by superimposing the compliances of the background and the fractures. The effective governing equations for fractured porous rocks are viscoelastic anisotropic and numerically solved by mixed-grid stencil frequency-domain finite-difference method. The main advantage of our proposed modeling scheme over poroelastic modeling schemes is that the fractured domain can be modeled using a viscoelastic solid, while the rest of the domain can be modeled using an elastic solid. We have tested the modeling scheme in a single fracture model, a fractured model, and a modified Marmousi model. The good consistency between the scattered waves off a single horizontal fracture calculated using our proposed scheme and the poroelastic modeling validates that our modeling scheme can properly capture the FPD effects. In the case of a set of aligned fractures, the scattered waves from the top and bottom of the fractured reservoir are strongly influenced by the FPD effects, and the reflected waves from the underlying formation can retain the relevant attenuation and dispersion information. The proposed numerical modeling scheme can also be used to improve migration quality and the estimation of fracture mechanical characteristics in inversion.

## 1 Introduction

Fluid saturated porous rocks in a reservoir, which are characterized by a heterogeneous internal structure consisting of a solid skeleton and interconnected fluid-filled voids, are often permeated by much more compliant and permeable fractures. Although the fractures typically occupy only a small volume, they tend to dominate the overall mechanical and hydraulic properties of

31 the reservoir (Liu et al., 2000; Gale et al., 2014). Thus, fracture detection, characterization, and imaging are of great importance  
32 for hydrocarbon exploration and production. Seismic waves are widely used for these purposes because their amplitude, phase,  
33 and anisotropy properties can be strongly affected by the fractures (Chapman, 2003; Gurevich, 2003; Brajanovski et al., 2005;  
34 Carcione et al., 2011; Rubino et al., 2014). Therefore, appropriate numerical modeling methods are required for the  
35 interpretation, migration and inversion of seismic data from porous media containing discrete distributed fractures.

36 Biot's poroelastic theory (Biot, 1956a; b) is the fundamental theory to describe elastic wave propagation in fluid porous media,  
37 including the dynamic interactions between rock and pore fluid. However, the original theory, assuming a macroscopically  
38 homogeneous porous media saturated by a single fluid phase, fails to explain the measured velocity dispersion and attenuation  
39 of seismic waves (Nakagawa et al., 2007). In recent decades, many researchers have found that if porous media contains  
40 mesoscale heterogeneity, a local fluid-pressure gradient will be induced at a scale comparable to the fluid pressure diffusion  
41 length at the seismic frequency band, thus causing significant velocity dispersion and attenuation (White et al., 1975; Dutta  
42 and Odé, 1979; Johnson, 2001; and Müller et al. 2008; Norris, 1993; Gurevich et al., 1997; Gelinsky and Shapiro, 1997;  
43 Kudarova et al., 2016). Fractures embedded in homogeneous porous background are special heterogeneities, exhibiting strong  
44 mechanical contrasts with background. When seismic waves travel through fluid saturated fractured porous rocks, local fluid  
45 pressure gradients will be induced between the fractures and the background in response to the strong compressibility contrast.  
46 To return the equilibrium state, fluid pressure diffusion (FPD) occurs between the fractures and the embedding background,  
47 which in turn changes the fluid stiffening effect on the fractures and thus their mechanical compliances depending on frequency  
48 (Barbosa et al., 2016a, b).

49 When the fractures with spacing and length much smaller than the wavelengths are uniformly and regularly distributed, the  
50 properties of the fractured rocks are homogeneous at macroscopic scale and can be described by a representative elementary  
51 volume (REV). Various effective medium theories are available for estimating the fracture-induced anisotropy, attenuation,  
52 and dispersion in a poroelastic context (Hudson, 1981; Thomsen, 1995; Chapman, 2003; Brajanovski et al., 2005; Krzikalla et  
53 al. 2011; Galvin et al., 2015; Guo et al., 2017a; b). However, large-scale fractures with much larger spacing and length typically  
54 have a more complex discrete distribution rather than a regular one, therefore the properties of rocks containing such fractures  
55 cannot be modeled by the effective medium theory. In contrast, the linear slip model (LSM) (Schoenberg, 1980), which  
56 represents individual fractures as nonwelded interfaces with discontinuous displacement tensors, is not limited by the  
57 assumption of regular distribution and can be used to model the discretely distributed fractures. Due to the discrete distribution,  
58 the effects of large-scale fractures are not uniform and vary spatially, which mean that their effects cannot be represented by a  
59 single REV. In the framework of LSM, two numerical schemes are available to assess the seismic response of discrete  
60 distributed large-scale fractures, the local effective-medium schemes (Coates and Schoenberg, 1995; Igel et al., 1997; Vlastos  
61 et al., 2003; Oelke, et al., 2013) and the explicit interface scheme (Zhang, 2005; Cui et al., 2018; Khokhlov, et al., 2021). The  
62 local effective-medium scheme uses a very coarse mesh to discretize background media and incorporates the additional effects

63 of fractures within each discretized cell based on LSM, that is, it regards each discretized cell as a REV. The advantage is that  
64 it requires no special treatment of the displacement discontinuity conditions on the fractures, which means no additional  
65 memory and computation costs. The explicit interface scheme uses a very fine mesh to discretize fractures and directly treats  
66 the displacement discontinuity across each fracture without any equivalent treatment, resulting an expensive memory and  
67 computation costs.

68 The common aspect of the aforementioned numerical modeling schemes is that they are all implemented in a purely elastic  
69 LSM with real-valued compliances boundary and represent both the embedding background and fractures as elastic solids, thus  
70 the impact of FPD effects on seismic scattering can't be accounted for. A dynamic linear slip model incorporating FPD effects  
71 should be considered when implementing numerical modeling of seismic wave propagating in fluid saturated porous rocks  
72 containing discrete distributed large-scale fractures. Nakagawa and Schoenberg (2007) developed an extended poroelastic  
73 LSM (PLSM) for a single fracture. The proposed model representing both the background and the fracture as poroelastic media  
74 can appropriately incorporate the frequency related effects, but it will also result in a higher computational consuming and  
75 more memory requirements. Rubino et al. (2015) proposed a frequency-dependent complex-valued normal compliance for a  
76 set of aligned fractures with a separation much smaller than the prevailing seismic wavelength. Despite the ability of including  
77 the FPD across the fractures, the model is not suitable for modeling discrete distributed fractures. In the context of  
78 viscoelasticity, Barbosa et al. (2016a) developed a viscoelastic linear slip model (VLSM) for an individual fracture with explicit  
79 complex-valued and frequency-dependent fracture compliances, to account for the impact of FPD on the fracture stiffness.  
80 That provides a viscoelasticity-based modeling algorithm for discrete distributed large-scale fractures with smaller  
81 computational costs and memory requirements than the poroelasticity based modeling.

82 In this paper, we develop a viscoelastic numerical modeling scheme to simulate seismic wave propagation in fluid-saturated  
83 porous media containing discrete distributed large-scale fractures. To capture the FPD effects between the fractures and  
84 background, we use the local effective medium theory based on Barbosa's VLSM to derive the effective anisotropic  
85 viscoelastic compliances in each numerical cell by superimposing the compliances of the background and the fractures. The  
86 effective anisotropic viscoelastic governing equations of the fractured porous rock are then numerically solved using mixed-  
87 grid stencil frequency-domain finite-difference method (FDFD) (Hustedt, et al. 2004; Operto, et al. 2009; Liu et al., 2018).  
88 Compare to poroelastic modeling scheme, the main advantage of our modeling scheme is that it uses VLSM-based viscoelastic  
89 modeling to account for FDP effects in the domain permeated by fractures, while in the rest fracture-free domain, it uses elastic  
90 modeling. To validate the proposed viscoelastic modeling scheme can capture the impact of FPD effects on seismic wave  
91 scattering, we compare the scattered waves of a single horizontal fracture obtained using our proposed modeling scheme with  
92 poroelastic modeling scheme and elastic modeling scheme. Numerical examples of a fractured reservoir are presented to  
93 demonstrate that the proposed modeling scheme can properly simulate the wave attenuation and dispersion due to the FPD  
94 effects between the fracture system and background. A set of rock physics models were generated by the Marmousi model to

95 test the proposed modeling scheme and code. The scheme can be used not only to study the impact of mechanical and hydraulic  
96 of fracture properties on seismic scattering but can also to improve migration quality and the estimation of fracture mechanical  
97 characteristics in inversion.

## 98 **2 Review of the LSM**

99 The LSM was originally proposed by Schoenberg (1980) to represent a solid- or fluid-infilled fracture permeated in a pure  
100 solid background, and then extended by other researchers (e.g. Nakagawa, Barbosa) to represent a poroelastic fracture to  
101 include the FPD effects. We briefly review the original LSM and its poroelastic and viscoelastic extensions.

### 102 **2.1 The original LSM**

103 Schoenberg (1980) presented the original LSM in the context of elasticity, representing both the background and the fracture  
104 as elastic solids. The original LSM assumes that across a fracture surface the stresses are continuous while the displacements  
105 are discontinuous. The discontinuous displacement vector of a horizontal fracture is linearly related to the stress tensor through  
106 the fracture compliance, which can be written as:

$$\begin{aligned} [u_x] &= Z_T \sigma_{xz}, \\ [u_y] &= Z_T \sigma_{yz}, \\ [u_z] &= Z_N \sigma_{zz}, \end{aligned} \quad (1)$$

108 where  $[u_i]$  are the discontinuous displacement components,  $\sigma_{ij}$  are the stress components,  $Z_N = h/H$  and  $Z_T = h/\mu$  are the  
109 normal and tangential compliance of the fracture, respectively.  $H$  and  $\mu$  are the  $P$ -wave and shear modulus of the fracture,  
110 and  $h$  is the thickness of the fracture. Due to the simple expression, the original LSM can be easily incorporated into the local  
111 effective medium theory to model seismic wave scattering off large-scale fractures. However, the original LSM was derived  
112 in a purely elastic context, only suitable for fractures filled with pure solids or fluids, thus it is not competent to describe the  
113 FPD effects.

### 114 **2.2 Nakagawa's PLSM**

115 Nakagawa and Schoenberg (2007) presented a PLSM in the framework of poroelasticity, representing the fracture as a highly  
116 compliant and porous thin isotropic, homogeneous layer embedded in a much stiffer and much less porous background  
117 (Nakagawa et al., 2007, Barbosa et al., 2016a). Similar to the classic LSM, the PLSM assumes that across a fracture surface  
118 the stresses are continuous while the displacements are discontinuous. The discontinuous displacement components for a  
119 horizontal fracture are (Nakagawa and Schoenberg, 2007):

$$\begin{aligned}
120 \quad [u_x] &= Z_T \sigma_{xz}, \\
[u_y] &= Z_T \sigma_{yz}, \\
[u_z] &= Z_{N_D} (\sigma_{zz} + \alpha P_f), \\
[w_z] &= -\alpha Z_{N_D} \left( \sigma_{zz} + \frac{1}{B} P_f \right),
\end{aligned} \quad (2)$$

121 where  $Z_{N_D} = h/H_D$  and  $Z_T = h/\mu$  are the fracture's drained normal compliance and tangential compliance, respectively,  $H_D$   
122 and  $H_U$  are the fracture's drained and undrained  $P$ -wave modulus, respectively,  $\alpha$  is the Biot's effective stress coefficient of  
123 the fracture,  $B = \alpha M/H_U$  is the fracture's uniaxial Skempton coefficient. Since the PLSM represents both the background  
124 and the fracture as poroelasticity, it is capable to describe the discontinuous displacement of the relative fluid in addition to  
125 the solid, implying that it can properly handle the FPD effects between the background and the fracture. Although it is difficult  
126 to incorporate the PLSM into the effective medium theory to obtain the effective moduli of the fractured porous rock, these  
127 boundary conditions can be easily incorporated into poroelastic finite-difference algorithm for modeling seismic wave  
128 scattering off large-scale fractures parallel to the coordinate axis. An alternative wavenumber domain method for modeling  
129 the scattered waves by poroelastic fractures is presented by Nakagawa and Schoenberg (2007) based on the PLSM.

### 130 2.3 Barbosa's VLSM

131 Barbosa et al. (2016a) derived a VLSM that account for the FPD effects between a fracture and background and the resulting  
132 stiffening effect impact on the fracture. The background is assumed to be not impacted by the FPD and can be represented by  
133 an elastic solid, whose properties are computed according to Gassmann's equation. By representing fractures as extremely thin  
134 viscoelastic layers, the poroelastic effects were incorporated into the classical LSM through complex-valued and frequency-  
135 dependent compliances. These compliances characterize the mechanical properties of the fluid-saturated fracture.

136 The discontinuous displacement components of the VLSM (Barbosa et al., 2016a) for a horizontal fracture are

$$\begin{aligned}
137 \quad [u_x] &= Z_T \sigma_{xz}, \\
[u_y] &= Z_T \sigma_{yz}, \\
[u_z] &= Z_N \sigma_{zz} + Z_X \varepsilon_{xx},
\end{aligned} \quad (3)$$

138 where  $Z_N$  and  $Z_T$  are generalized normal and tangential compliances of the fracture respectively, and  $Z_X$  is a dimensionless  
139 parameter that related to the coupling between horizontal and vertical deformation of the fracture. The normal compliance  $Z_N$   
140 and additional parameter  $Z_X$  are complex-valued and frequency-dependent, while the tangential compliance  $Z_T = h/\mu$  is the  
141 same as for elastic and poroelastic models. The two frequency-dependent and complex-valued compliances are:

$$\begin{aligned}
142 \quad Z_N &= Z_{N_U} + Z_{N_D} \frac{G_1(1+i)}{\sqrt{\omega + G_2(1+i)}}, \\
Z_X &= -\frac{G_3(1+i)}{\sqrt{\omega + G_4(1+i)}},
\end{aligned} \quad (4)$$

143 where  $Z_{N_U} = h/H_U$  and  $Z_{N_D} = h/H_D$  are the fracture's undrained and drained normal compliance respectively,  $\omega$  is the  
 144 angular frequency. The four real-valued parameters  $G_1, G_2, G_3$  and  $G_4$  are defined as

$$145 \quad G_1 = \frac{\kappa^b (B^b - B^f)^2}{\eta Z_{N_D} \sqrt{D^b}}, \quad G_2 = \frac{\kappa^b B^f}{\eta Z_{N_D} \alpha^f \sqrt{D^b}}, \quad G_3 = \frac{2\sqrt{2}\alpha^b \mu^b (B^f - B^b) \sqrt{D^b}}{H_D^b}, \quad G_4 = \frac{\sqrt{2}\kappa^b D^f}{Z_T \mu^f \kappa^f \sqrt{D^b}}, \quad (5)$$

146 where  $\kappa$  is the permeability,  $\eta$  is the viscosity of the fluid,  $D = \frac{\kappa H_D M}{\eta H_U}$  is the diffusivity, the other parameters are defined in  
 147 the same way as in poroelasticity. The parameters in Eq. (5) with superscripts  $b$  correspond to background properties and the  
 148 parameters with superscripts  $c$  correspond to fracture parameters.

149 In the low-frequency limit, the two frequency-dependent and complex-valued parameters become:

$$150 \quad Z_N = Z_{N_U} + Z_{N_D} \frac{G_1}{G_2}, \quad (6)$$

$$Z_X = -\frac{G_3}{G_4}.$$

151 The frequency-independent and real-valued parameters in Eq. (6) indicate the elastic behavior of the fracture, which is expected,  
 152 since the fluid pressure between the fracture and background at low frequencies has enough time to equilibrate within a half-  
 153 wave period (i.e. the fracture is softest), resulting in no dispersion and attenuation of the seismic waves.

154 In the high-frequency limit, the two frequency-dependent and complex-valued parameters become:

$$155 \quad Z_N = Z_{N_U}, \quad (7)$$

$$Z_X = 0.$$

156 Equation (7) indicates that the fracture model collapses to an elastic thin layer model in the high-frequency limit, which is  
 157 consistent with the original LSM that computes the properties of both fracture and background using Gassmann's equations.  
 158 This because at high frequencies, the fluid pressure between the fracture and background has no time to equilibrate within a  
 159 half-wave period, i.e. the fracture is hardest and behaves as being sealed. The VLSM considering FPD effects can be  
 160 incorporated into the local effective medium theory to simulate the poroelastic seismic response of large-scale fractures, while  
 161 its low- and high-frequency limits can be used to model the elastic seismic response.

162 In the VLSM, according to Barbosa et al. (2016a), there are two distinct frequency regimes frequency-dependent fracture  
 163 compliance due to FPD, and the characteristic frequency for the transition between the two regimes is:

$$164 \quad \omega_m = 2\pi f_m = \left(\frac{2}{h}\right)^2 \left(\frac{e_b^2}{e_f^2 + e_f e_b}\right) D_f, \quad (8)$$

165 where  $h$  is the thickness of the fracture,  $D$  is the diffusivity,  $e = \kappa/\eta\sqrt{D}$ , the superscripts  $b$  and  $f$  correspond to background  
 166 fracture parameters, respectively.

### 167 3 Seismic modeling of fractured porous rock

168 In this section, we focus on the implementation of seismic modeling of fluid-saturated porous media containing discrete  
 169 distributed large-scale fractures in 2D case. We develop a viscoelastic modeling scheme based on the VLSM and local effective  
 170 medium theory (Coates and Schoenberg, 1995) to incorporate the FPD effects between fractures and background. To validate  
 171 that the proposed viscoelastic modeling scheme can capture the impact of FPD effects on seismic wave scattering of fractures,  
 172 we outline the implementation of poroelastic modeling scheme using an explicit application of the PLSM.

### 173 3.1 viscoelastic modeling based on VLSM

174 To incorporate the VLSM into viscoelastic finite-difference modeling algorithms, we adopt Coates and Schoenberg's local  
 175 effective media theory (1995) to account for the property of each fracture. We first provide the specific derivation of the  
 176 effective viscoelastic-anisotropic stiffness matrix of the numerical cell by superimposing the compliances of the background  
 177 and the fractures. The porous background is assumed to be unaffected by the FPD in the presence of fractures because of the  
 178 small amount of diffusing fluid and large compliance contrast between background and fluid. Thus, the rock background can  
 179 be represented by an elastic homogeneous solid and its strain tensor  $\boldsymbol{\varepsilon}^b$  can be expressed as

$$180 \quad \varepsilon_{ij}^b = s_{ijkl}^b \sigma_{kl}, \quad (i, j = x, y, z) \quad (9)$$

181 where the compliance tensor  $\mathbf{s}^b$  is computed according to Gassmann's equation (Rubino et al., 2015), and  $\boldsymbol{\sigma}$  is the average stress  
 182 tensor. The exceed strain tensor  $\boldsymbol{\varepsilon}^c$  induced by a single fracture with surface  $S$  in a representative volume  $V$  (e.g. the volume of  
 183 numerical cell) is given by (Hudson and Knopoff, 1989; Sayers and Kachanov, 1995; Liu, et al., 2000)

$$184 \quad \varepsilon_{ij}^c = s_{ijkl}^c \sigma_{kl} = \frac{1}{2V} \int ([u_i] n_j + [u_j] n_i) dS, \quad (10)$$

185 where  $\mathbf{s}^c$  is the extra compliance tensor resulting from the fractures,  $[u_i]$  is the  $i$ th component of the displacement  
 186 discontinuity on  $S$ ,  $n_i$  is the  $i$ th component of the fracture normal. Note that Eq. (10) is applicable to finite, nonplanar fractures  
 187 in the long wavelength limit, i.e., the applied stress is assumed to be constant over the representative volume.

188 If we assume that the interface of the fracture is normal to the  $z$ -axis (fracture normal vector  $\mathbf{n}$  is  $(0,0,1)$ ), substituting Eq. (3)  
 189 into Eq. (10), we can obtain the nonzero element of the exceed fracture strain tensor:

$$190 \quad \begin{aligned} \varepsilon_{xz}^c &= \frac{S}{V} Z_T \sigma_{xz}, \\ \varepsilon_{yz}^c &= \frac{S}{V} Z_T \sigma_{yz}, \\ \varepsilon_{zz}^c &= \frac{S}{V} (Z_N \sigma_{zz} + Z_X \varepsilon_{xx}^b). \end{aligned} \quad (11)$$

191 For simplicity, we use an abbreviated Voigt notation for the stresses, strains, and stiffness and compliance tensors, and rewrite  
 192 the Eq. (9) and Eq. (11) as:

$$193 \quad \hat{\boldsymbol{\varepsilon}}^b = \hat{\mathbf{S}}^b \hat{\boldsymbol{\sigma}}, \quad (12)$$

194  $\hat{\boldsymbol{\varepsilon}}^c = \frac{S}{V}(\hat{\mathbf{Z}}^I \hat{\boldsymbol{\sigma}} + \hat{\mathbf{Z}}^{II} \hat{\boldsymbol{\varepsilon}}) = \frac{S}{V}(\hat{\mathbf{Z}}^I + \hat{\mathbf{Z}}^{II} \hat{\mathbf{S}}^b) \hat{\boldsymbol{\sigma}}, \quad (13)$

195 where  $\hat{\boldsymbol{\varepsilon}} = [\varepsilon_{xx}, \varepsilon_{yy}, \varepsilon_{zz}, 2\varepsilon_{yz}, 2\varepsilon_{xz}, 2\varepsilon_{xy}]^T$  is the strain matrix,  $\hat{\boldsymbol{\sigma}} = [\sigma_{xx}, \sigma_{yy}, \sigma_{zz}, \sigma_{yz}, \sigma_{xz}, \sigma_{xy}]^T$  is the stress matrix, and  $\hat{\mathbf{S}}^b$  is the  
 196 compliance matrix of background. Note that in this paper the " $\wedge$ " symbol is used to indicate matrices to distinguish them  
 197 from tensors, which is used to distinguish a tensor. The  $6 \times 6$  fracture compliance matrix  $\hat{\mathbf{Z}}^I$  and additional dimensionless  
 198 matrix  $\hat{\mathbf{Z}}^{II}$  according to the Voigt notation are defined as

199 
$$\hat{\mathbf{Z}}^I = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & Z_N & 0 & 0 & 0 \\ 0 & 0 & 0 & Z_T & 0 & 0 \\ 0 & 0 & 0 & 0 & Z_T & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad \hat{\mathbf{Z}}^{II} = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ Z_X & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}, \quad (14)$$

200 The average strain in a homogeneous porous rock containing single fracture can be expressed as the sum of the strains of  
 201 background and the fractures

202  $\hat{\boldsymbol{\varepsilon}} = \hat{\boldsymbol{\varepsilon}}^b + \hat{\boldsymbol{\varepsilon}}^c. \quad (15)$

203 Substituting Eq. (12) and Eq. (13) into Eq. (15), we can obtain the average strain matrix

204  $\hat{\boldsymbol{\varepsilon}} = \left[ \hat{\mathbf{S}}^b + \frac{S}{V}(\hat{\mathbf{Z}}^I + \hat{\mathbf{Z}}^{II} \hat{\mathbf{S}}^b) \right] \hat{\boldsymbol{\sigma}}. \quad (16)$

205 Thus, the effective stiffness matrix  $\mathbf{C}$  can be expressed as

206  $\mathbf{C} = \left[ \hat{\mathbf{S}}^b + \frac{S}{V}(\hat{\mathbf{Z}}^I + \hat{\mathbf{Z}}^{II} \hat{\mathbf{S}}^b) \right]^{-1}. \quad (17)$

207 The effective stiffness matrix of case of an inclined fracture can be obtained by rotating the coordinate axis to keep  $z$ -axis  
 208 perpendicular to fracture interface. We define the inclined fracture have an angle  $\varphi$  and an azimuth angle  $\theta$ , and then the  
 209 rotation matrix can be obtained:

210 
$$\hat{\mathbf{R}} = \begin{bmatrix} \cos \theta \cos \varphi & -\sin \theta & \cos \theta \sin \varphi \\ \sin \theta \cos \varphi & \cos \theta & \sin \theta \sin \varphi \\ -\sin \varphi & 0 & \cos \varphi \end{bmatrix}, \quad (18)$$

211 as well as the corresponding stress Bond matrix  $\hat{\mathbf{A}}_\sigma(\hat{\mathbf{R}})$  and strain Bond matrix  $\hat{\mathbf{A}}_\varepsilon(\hat{\mathbf{R}})$ . The new stress matrix  $\hat{\boldsymbol{\varepsilon}}'$  and strain  
 212 matrix  $\hat{\boldsymbol{\sigma}}'$  can be expressed as:

213  $\hat{\boldsymbol{\varepsilon}}' = \hat{\mathbf{A}}_\varepsilon \hat{\boldsymbol{\varepsilon}}, \quad \hat{\boldsymbol{\sigma}}' = \hat{\mathbf{A}}_\sigma \hat{\boldsymbol{\sigma}}. \quad (19)$

214 By substituting Eq. (19) into Eq. (13), the new exceed fracture strain matrix can be obtained

215  $\hat{\boldsymbol{\varepsilon}}^c = \frac{S}{V} \hat{\mathbf{A}}_\varepsilon (\hat{\mathbf{Z}}^I + \hat{\mathbf{Z}}^{II} \hat{\mathbf{S}}^b) \hat{\mathbf{A}}_\sigma^T \hat{\boldsymbol{\sigma}}, \quad (20)$

216 Finally, substituting Eq. (12) and Eq. (20) into Eq. (15), the average strain matrix of each numerical cell containing discrete  
 217 distributed fractures with the same arbitrary direction can be expressed as

218  $\hat{\mathbf{e}} = \left[ \hat{\mathbf{S}}^b + \frac{S}{V} \hat{\mathbf{A}}_\varepsilon \left( \hat{\mathbf{Z}}^I + \hat{\mathbf{Z}}^{II} \hat{\mathbf{S}}^b \right) \hat{\mathbf{A}}_\varepsilon^T \right] \hat{\mathbf{g}}. \quad (21)$

219 and the corresponding effective stiffness matrix  $\mathbf{C}$  is

220  $\mathbf{C} = \left[ \hat{\mathbf{S}}^b + \frac{S}{V} \hat{\mathbf{A}}_\varepsilon \left( \hat{\mathbf{Z}}^I + \hat{\mathbf{Z}}^{II} \hat{\mathbf{S}}^b \right) \hat{\mathbf{A}}_\varepsilon^T \right]^{-1}. \quad (22)$

221 If the background media is isotropic, the  $\mathbf{C}$  can be simplified as

222  $\mathbf{C} = \mathbf{C}^{iso} \left[ \mathbf{I} + \frac{S}{V} \hat{\mathbf{A}}_\varepsilon \left( \hat{\mathbf{Z}}^I \mathbf{C}^{iso} + \hat{\mathbf{Z}}^{II} \right) \hat{\mathbf{A}}_\varepsilon^T \right]^{-1}. \quad (23)$

223 If we ignore the interaction between different fractures and the FPD along the fracture interfaces, the result can be easily  
224 extended to the case of multiple sets of discrete distributed large-scale fractures with arbitrary orientation:

225  $\mathbf{C} = \mathbf{C}^{iso} \left[ \mathbf{I} + \sum_{r=1}^{N_c} \frac{S_r}{V} \hat{\mathbf{A}}_{\varepsilon r} \left( \hat{\mathbf{Z}}_r^I \mathbf{C}^{iso} + \hat{\mathbf{Z}}_r^{II} \right) \hat{\mathbf{A}}_{\varepsilon r}^T \right]^{-1}. \quad (24)$

226 where  $N_c$  is total number of the fracture directions and the subscript  $r$  denotes the  $r$ th direction. The derived effective stiffness  
227 matrix is to be employed in the viscoelastic finite-difference modeling of discrete distributed large-scale fractures in porous  
228 rock.

229 Since the local effective medium theory assumes that the real structure of the fractured porous rock is substituted by ideal  
230 continua, the balance equations of classical continuum mechanics can be applied without considering the discontinuity at the  
231 fracture interfaces, and the constitutive equations can be characterized by the effective viscoelastic stiffness. Combined with  
232 the effective complex-valued and frequency-dependent TTI viscoelastic stiffness, the 2-D frequency-domain second-order  
233 heterogeneous governing equations with PML of fractured porous rock can be expressed as:

234 
$$\begin{aligned} \omega^2 \rho u_x + \frac{1}{\xi_x} \partial_x \left( \frac{c_{11}}{\xi_x} \partial_x u_x + \frac{c_{13}}{\xi_z} \partial_z u_z + \frac{c_{15}}{\xi_z} \partial_z u_x + \frac{c_{15}}{\xi_x} \partial_x u_z \right) + \frac{1}{\xi_z} \partial_z \left( \frac{c_{15}}{\xi_x} \partial_x u_x + \frac{c_{35}}{\xi_z} \partial_z u_z + \frac{c_{55}}{\xi_z} \partial_z u_x + \frac{c_{55}}{\xi_x} \partial_x u_z \right) &= 0, \\ \omega^2 \rho u_z + \frac{1}{\xi_x} \partial_x \left( \frac{c_{15}}{\xi_x} \partial_x u_x + \frac{c_{35}}{\xi_z} \partial_z u_z + \frac{c_{55}}{\xi_z} \partial_z u_x + \frac{c_{55}}{\xi_x} \partial_x u_z \right) + \frac{1}{\xi_z} \partial_z \left( \frac{c_{13}}{\xi_x} \partial_x u_x + \frac{c_{33}}{\xi_z} \partial_z u_z + \frac{c_{35}}{\xi_z} \partial_z u_x + \frac{c_{35}}{\xi_x} \partial_x u_z \right) &= 0, \end{aligned} \quad (25)$$

235 where  $u_x$  and  $u_z$  are the horizontal and vertical components of particle displacement vector,  $\rho$  is the effective density, and  $c_{ij}$   
236 are the components of complex-valued and frequency-dependent effective stiffness matrix,  $\xi_x$  and  $\xi_z$  are the frequency domain  
237 PML damping functions.

238 In time domain, the governing equations are integral differential equations, which require special processing for the  
239 convolution operations, resulting in high computational costs. Although the problem can be relieved by memory functions, it  
240 still requires high memory requirements. Instead, the governing equations can be straightforwardly solved using FDFD. To  
241 efficiently and accurately modelling of seismic wave propagation in fluid saturated fractured porous rock, we solve the second-  
242 order heterogeneous governing equations with mixed-grid stencil FDFD method (Jo et al., 1996; Hustedt et al. 2004). The  
243 mixed system of governing equations is formulated by combining the classical Cartesian coordinate system (CS) and the 45°-  
244 rotated coordinate system (RS):

$$\begin{aligned} \omega^2 \rho u_x + w_1 (A_c u_x + B_c u_z) + (1-w_1)(A_r u_x + B_r u_z) &= 0, \\ \omega^2 \rho u_z + w_1 (C_c u_x + D_c u_z) + (1-w_1)(C_r u_x + D_r u_z) &= 0, \end{aligned} \quad (26)$$

where the optimal averaging coefficient  $w_1 = 0.5461$  (Jo et al., 1996). The coefficients  $A_c, B_c, C_c, D_c$  and  $A_r, B_r, C_r, D_r$  are functions of the damping functions, effective stiffness coefficients and spatial derivative operators and the detailed expressions are given in Appendix A. We follow Hustedt et al., (2004) and Liu et al., (2018) to discretize the derivative operation on the mixed systems using mixed grid stencil. After discretization and arrangement, the mixed system of governing equations can be written in matrix form as

$$\begin{bmatrix} \mathbf{M} + w_1 \mathbf{A}_c + (1-w_1) \mathbf{A}_r & w_1 \mathbf{B}_c + (1-w_1) \mathbf{B}_r \\ w_1 \mathbf{C}_c + (1-w_1) \mathbf{C}_r & \mathbf{M} + w_1 \mathbf{D}_c + (1-w_1) \mathbf{D}_r \end{bmatrix} \begin{bmatrix} \mathbf{u}_x \\ \mathbf{u}_z \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}, \quad (27)$$

where  $\mathbf{M}$  denotes the diagonal mass matrix of coefficients  $\omega^2 \rho$ , and blocks  $\mathbf{A}_c, \mathbf{B}_c, \mathbf{C}_c, \mathbf{D}_c$  and  $\mathbf{A}_r, \mathbf{B}_r, \mathbf{C}_r, \mathbf{D}_r$  form the stiffness matrices for the CS and RS stencils, respectively, and the corresponding coefficients of submatrices are given in Appendix B.

To improve the modelling accuracy of mixed-grid stencil, the acceleration term  $\omega^2 \rho$  are approximated using a weighted average over the mixed operator stencil nodes:

$$[\omega^2 \rho]_{ij} \approx \omega^2 [w_{m1} \rho_{ij} + w_{m2} (\rho_{i+1,j} + \rho_{i-1,j} + \rho_{i,j+1} + \rho_{i,j-1}) + w_{m3} (\rho_{i+1,j+1} + \rho_{i-1,j-1} + \rho_{i-1,j+1} + \rho_{i+1,j-1})], \quad (28)$$

where the optimal coefficients  $w_{m1} = 0.6248$ ,  $w_{m2} = 0.09381$  and  $w_{m3} = (1 - w_{m1} - 4w_{m2})/4$  are computed by Jo et al. (1996).

In order to assess the FPD effects on seismic response, a similar procedure can be adopted in the implementation of elastic modeling by replacing the frequency-dependent fracture compliances with its low- or high-frequency limit compliances. The main advantage of our VLSM-based modeling scheme over poroelastic modeling schemes is that the fractured domain can be modeled using a viscoelastic solid, while the rest of the domain can be modeled using an elastic solid.

### 3.2 Poroelastic modeling based on PLSM

The poroelastic modeling means that we numerically solve the Biot's equations and adopt an explicit implementation of the PLSM across each fracture instead of using the effective media theory. Hence, the poroelastic modeling can naturally deal with the FPD between fracture and background and account for its impact on wave scattering. To verify the effectiveness of the viscoelastic modeling based on VLSM, we compared the results obtained from viscoelastic scheme with those obtained from the poroelastic scheme. Although it is difficult to implement an explicit application of PLSM for arbitrary orientated fracture, it is relatively straightforward for horizontal or vertical fracture. In the following text, we outline the poroelastic modeling for a single horizontal fracture embedded in an isotropic homogeneous background with an explicit implementation of the PLSM. In frequency domain, the governing equations for an isotropic poroelastic media in the absent of fractures can be written as (Biot, 1962):

$$\begin{aligned}
& -\omega^2 \rho u_i - \omega^2 \rho_f w_i = \partial_i \sigma_{ij}, \\
273 \quad & -\omega^2 \rho_f u_i - \omega^2 \rho_w w_i + i\omega \frac{\eta}{\kappa} w_i = -\partial_i P_f, \\
& \sigma_{ij} = (H_U - 2\mu) \partial_i u_j + \alpha M \partial_i w_j + \mu (\partial_j u_i + \partial_i u_j), \\
& -P_f = \alpha M \partial_i u_i + M \partial_i w_i.
\end{aligned} \tag{29}$$

274 In the presence of fractures, the spatial derivative of stress remains unchanged. However, due to the discontinuity of particle  
275 displacements across the fracture interface, its spatial derivative consists of two parts, i.e. the background and the fracture:

$$\begin{aligned}
& \frac{\partial u_x}{\partial z} = \left( \frac{\partial u_x}{\partial z} \right)_{BG} + \left( \frac{\partial u_x}{\partial z} \right)_{FR}, \\
276 \quad & \frac{\partial u_z}{\partial z} = \left( \frac{\partial u_z}{\partial z} \right)_{BG} + \left( \frac{\partial u_z}{\partial z} \right)_{FR}, \\
& \frac{\partial w_z}{\partial z} = \left( \frac{\partial w_z}{\partial z} \right)_{BG} + \left( \frac{\partial w_z}{\partial z} \right)_{FR}.
\end{aligned} \tag{30}$$

277 The spatial derivative of the background is described by the Eq. (29):

$$\begin{aligned}
& \left( \frac{\partial u_x}{\partial x} \right)_{BG} = \frac{H_D}{4\mu(H_D - \mu)} \sigma_{xx} - \frac{H_D - 2\mu}{4\mu(H_D - \mu)} \sigma_{zz} + \frac{2\alpha\mu}{4\mu(H_D - \mu)} P_f, \\
278 \quad & \left( \frac{\partial u_z}{\partial z} \right)_{BG} = -\frac{H_D - 2\mu}{4\mu(H_D - \mu)} \sigma_{xx} + \frac{H_D}{4\mu(H_D - \mu)} \sigma_{zz} + \frac{2\alpha\mu}{4\mu(H_D - \mu)} P_f, \\
& \left( \frac{\partial w_x}{\partial x} + \frac{\partial w_z}{\partial z} \right)_{BG} = -\frac{2\alpha\mu}{4\mu(H_D - \mu)} \sigma_{xx} - \frac{2\alpha\mu}{4\mu(H_D - \mu)} \sigma_{zz} - \frac{H_U - \mu}{M(H_D - \mu)} P_f.
\end{aligned} \tag{31}$$

279 The fracture induced spatial derivative can be obtained based on the PLSM:

$$\begin{aligned}
& \left( \frac{\partial u_x}{\partial z} \right)_{FR} = \frac{\Delta u_x}{\Delta z} = \frac{Z_T}{\Delta z} \sigma_{xz}, \\
280 \quad & \left( \frac{\partial u_z}{\partial z} \right)_{FR} = \frac{\Delta u_z}{\Delta z} = \frac{Z_{N_D}}{\Delta z} (\sigma_{zz} + \alpha P_f), \\
& \left( \frac{\partial w_z}{\partial z} \right)_{FR} = \frac{\Delta w_z}{\Delta z} = -\frac{Z_{N_D}}{\Delta z} \left( \alpha \sigma_{zz} + \frac{H_U}{M} P_f \right).
\end{aligned} \tag{32}$$

281 By substituting equations (31)-(32) into Eq. (30) and rewritten Eq. (29), we obtain the governing equations for numerical  
282 simulation of elastic wave in fractured poroelastic media in matrix form:

$$283 \quad -\omega^2 \hat{\mathbf{R}} \hat{\mathbf{u}} = \nabla \hat{\mathbf{S}}^{-1} \nabla^T \hat{\mathbf{u}}, \tag{33}$$

284 where  $\hat{\mathbf{u}} = (u_x, u_z, w_x, w_z)^T$  is the displacement vector,  $\hat{\mathbf{R}}$ ,  $\hat{\mathbf{S}}$  and  $\nabla$  are the density, compliance and spatial derivative matrix,  
285 respectively. The three matrices in Eq. (33) are defined as:

$$286 \quad \hat{\mathbf{R}} = \begin{bmatrix} \rho & 0 & \rho_f & 0 \\ 0 & \rho & 0 & \rho_f \\ \rho_f & 0 & \rho_m & 0 \\ 0 & \rho_f & 0 & \rho_m \end{bmatrix}, \quad \left( \rho_m = \rho_w - \frac{i\eta}{\omega\kappa} \right). \tag{34}$$

$$\nabla = \begin{bmatrix} \partial_x & 0 & \partial_z & 0 \\ 0 & \partial_z & \partial_x & 0 \\ 0 & 0 & 0 & \partial_x \\ 0 & 0 & 0 & \partial_z \end{bmatrix}, \quad (35)$$

$$\hat{\mathbf{S}} = \begin{bmatrix} \frac{H_D}{4\mu(H_D - \mu)} & -\frac{H_D - 2\mu}{4\mu(H_D - \mu)} & 0 & -\frac{2\alpha\mu}{4\mu(H_D - \mu)} \\ \frac{H_D - 2\mu}{4\mu(H_D - \mu)} & \frac{H_D}{4\mu(H_D - \mu)} + \frac{Z_{N_D}}{\Delta z} & 0 & -\frac{2\alpha\mu}{4\mu(H_D - \mu)} - \frac{\alpha Z_{N_D}}{\Delta z} \\ 0 & 0 & \frac{1}{\mu} + \frac{Z_T}{\Delta z} & 0 \\ -\frac{2\alpha\mu}{4\mu(H_D - \mu)} & -\frac{2\alpha\mu}{4\mu(H_D - \mu)} - \frac{\alpha Z_{N_D}}{\Delta z} & 0 & -\frac{H_U - \mu}{M(H_D - \mu)} - \frac{H_U Z_{N_D}}{M \Delta z} \end{bmatrix}. \quad (36)$$

A compact discretized wave equation system that contains only displacement field can be obtained by using second-order difference operators to discretize the new governing equations:

$$\begin{bmatrix} \mathbf{G}_{11} & \mathbf{G}_{12} & \mathbf{G}_{13} & \mathbf{G}_{14} \\ \mathbf{G}_{21} & \mathbf{G}_{22} & \mathbf{G}_{23} & \mathbf{G}_{24} \\ \mathbf{G}_{31} & \mathbf{G}_{32} & \mathbf{G}_{33} & \mathbf{G}_{34} \\ \mathbf{G}_{41} & \mathbf{G}_{42} & \mathbf{G}_{43} & \mathbf{G}_{44} \end{bmatrix} \begin{bmatrix} \mathbf{u}_x \\ \mathbf{u}_z \\ \mathbf{w}_x \\ \mathbf{w}_z \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \\ \mathbf{0} \\ \mathbf{0} \end{bmatrix}, \quad (37)$$

where blocks  $\mathbf{G}_{i,j}$  ( $i, j = 1 \dots 4$ ) forms the stiffness matrices of the discretized system of the poroelastic wave equations. The poroelastic modeling based on PLSM will be used to validate the other modeling schemes.

In this section, we apply different numerical modeling schemes on three fractured models to examine the FPD effects on seismic wave scattering. We mainly focus on the amplitudes and phases of the scattered and reflected waves.

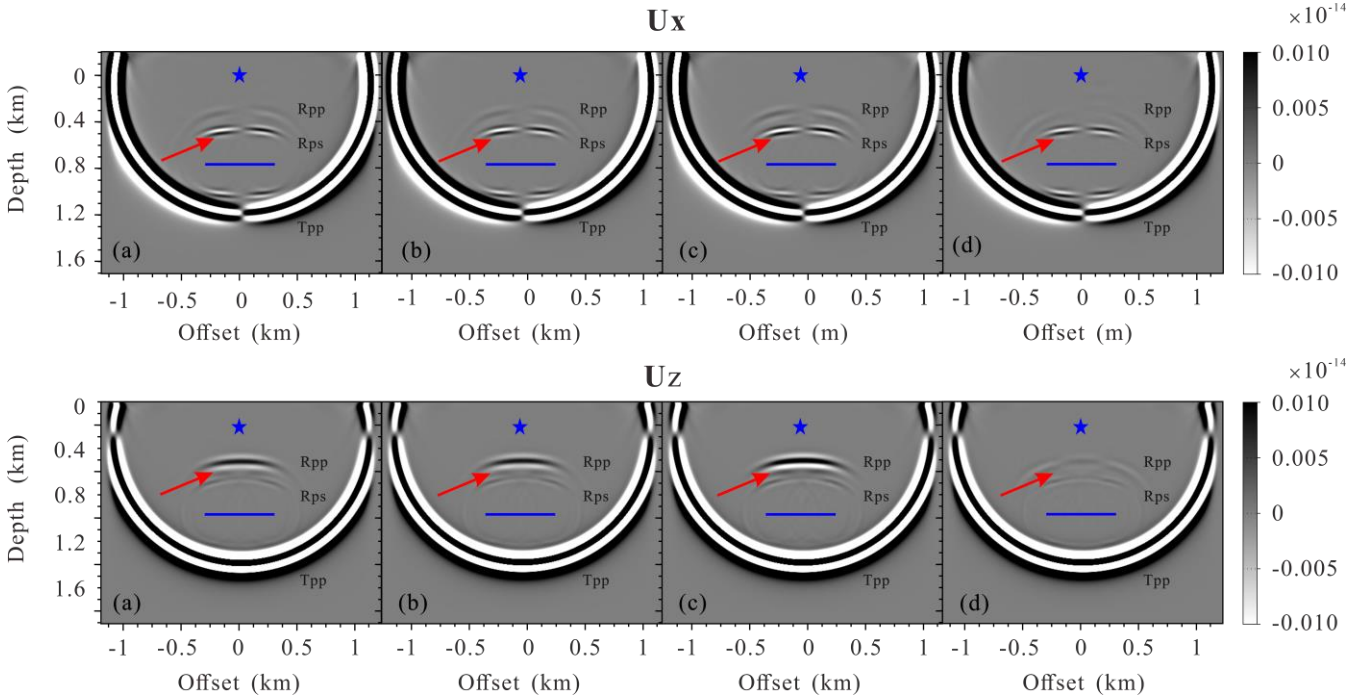

##### 4.1 Single fracture model

Here, we numerically simulate the scattering of seismic waves from a single fracture embedded in a homogeneous background. The model measures  $2000m \times 1500m$  with a grid interval 5m (namely, the numerical grids size is  $401 \times 301$ ) surrounded by a

300 200m thick PML boundary. The fracture is parallel to the  $x$ -axis (a horizontal fracture) and located 750m directly below the  
 301 source (1000m, 30m), with a 500m horizontal extending. A Ricker wavelet with a central frequency of 35Hz is used as the  
 302 temporal source excitation. The material properties of the fracture and background are given in Table 1 modified from  
 303 Nakagawa and Schoenberg (2007) and Barbosa et al. (2016a). For comparison, we present the seismic wavefields obtained  
 304 using the poroelastic modeling based on PLSM, the viscoelastic modeling based on VLSM, as well as the elastic modeling  
 305 based on low-frequency limit of VLSM (LVLSM) and high-frequency limit of VLSM (HVLSM). For the convenience of  
 306 observation of the impact of the FPD on the scattered  $P$ - and  $S$ -wave of the fracture, we apply the pressure source in all four  
 307 schemes.

308

 314 **elastic modeling. The blue asterisk and line represent the source and the fracture, respectively.**

315

316

**Figure 3: Comparison of 1-D seismograms components  $U_x$  and  $U_z$  at (1200m, 0m) for a single horizontal fracture model.**

317

Figure 1 shows the complex-valued and frequency-dependent fracture normal compliance  $Z_N$  and dimensionless parameter  $Z_x$  computed from Eq. (6). The mechanical compliance of the fracture is strongly controlled by FPD effects. It can be observed that the real part of the fracture normal compliance decreases with the increment of frequency, while the imaginary part has a peak at the characteristic frequency, corresponding to the maximal dispersion. The central frequency (35Hz) of the Ricker wavelet used for numerical simulation is close to the characteristic frequency (46Hz), which ensures that the impact of the FDP effects on seismic scattering is significant in the seismic frequency band.

323

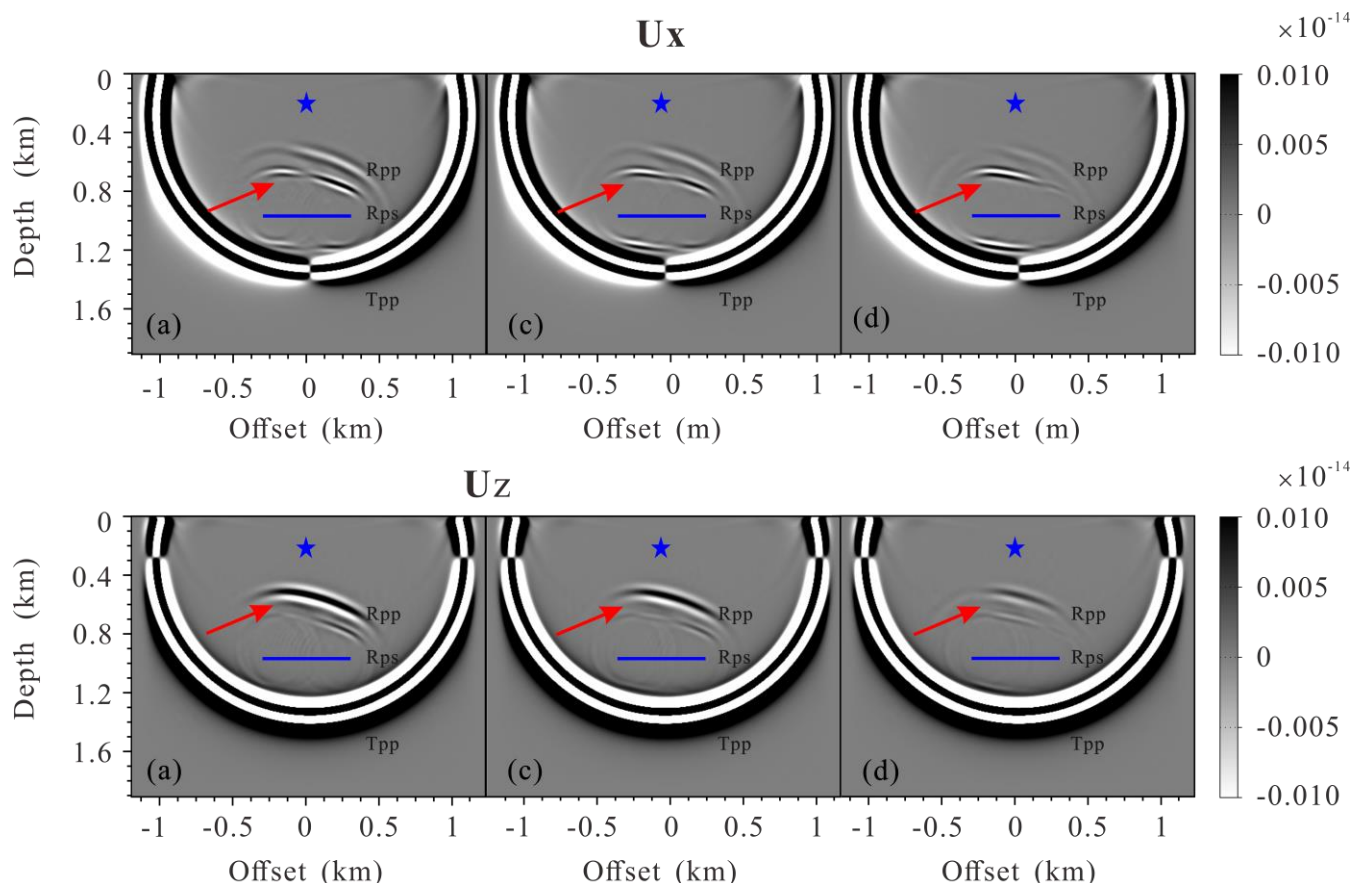

Figure 2 shows the 280ms snapshots of the displacement fields for the single horizontal fracture model models. The displacement fields are calculated by the PLSM-based poroelastic modeling, the VLMSM-based viscoelastic modeling, the LVLSM-based elastic modeling and the HVLSM-based elastic modeling, respectively. The asterisk represents the source and the blue line represents the fracture. To make the small scattered wave visible, large amplitude is clipped, thus the transmitted compressional waves ( $T_{PP}$ ), scattered compressional waves ( $S_{PP}$ ) and scattered converted waves ( $S_{PS}$ ) can be seen clearly. It should note that the slow  $P$ -waves are invisible in the poroelastic modeling, due to the high diffusion and attenuation of slow  $P$ -waves in the background media. Figure 3 present the comparison of 1-D seismograms at (1200m, 0m).

330

We consider the poroelastic modeling as a reference scenario because it can naturally incorporate the FPD effects. Figures 2 and 3 suggest very good agreement between the  $S_{PP}$  amplitude calculated using the PLSM-based and VLMSM-based modeling, while the HVLSM-based modeling obviously underestimate the  $S_{PP}$  amplitude, and the LVLSM-based modeling overestimate the  $S_{PP}$  amplitude. This is to be expected, since the scattering behavior of a fracture is mainly controlled by the stiffness contrast with respect to the background. The HVLSM assumes there is insufficient time for fluid exchange at the fracture interface, the fracture behaves as being sealed and the stiffness of the saturated fracture is maximal, resulting in an underestimated stiffness contrast between fracture and background. The LVLSM assumes there is enough time for fluid flow between the fracture and background, the deformation of the fracture is maximal, resulting in an overestimated stiffness contrast with background. The VLMSM derived from poroelastic theory, however, can properly incorporate the FPD effects, leading to a frequency-dependent

338

339 stiffness contrast equivalent to the PLSM. It can be note that the  $S_{pp}$  amplitudes obtained using the LVLSM-based modeling  
 340 is comparable to that of the PLSM based modeling, because the FPD effects mainly occur at seismic frequencies closer to the  
 341 low frequency limit. The  $S_{pp}$  travel time obtained using the four modeling schemes shows good consistency. Figures 2 and 3  
 342 also show that the discrepancy of the  $S_{ps}$  amplitudes is almost negligible. Because the  $S$ -wave scattering behavior is mainly  
 343 controlled by the drained stiffness contrast between the fracture and the background. The comparison of different modeling  
 344 schemes demonstrates that the DLISM-based viscoelastic modeling can appropriately capture the FPD effects on wave  
 345 scattering of a fluid saturated fracture, while the two elastic modeling cannot correctly estimate the scattered waves.

346  
 347 **Figure 4: Snapshots of the wavefields components  $U_x$  and  $U_z$  for a single inclined fracture model at 280ms: (a) the PLSM based**  
 348 **poroelastic modeling, (b) the VLISM based viscoelastic modeling, (c) the LVLSM based elastic modeling and (d) the HVLSM based**  
 349 **elastic modeling. The blue asterisk and line represent the source and the fracture, respectively.**

350

351

**Figure 5: Comparison of 1-D seismograms components Ux and Uz at (1000m, 0m) for a single inclined fracture model.**

352

The proposed modeling scheme is also applicable to the inclined fracture. Figure 4 shows the 280ms snapshots of the

353

displacement fields for the single inclined fracture model models. Figure 5 is the comparison of 1-D seismograms at

354

(1200m,0m). Figures 4 and 5 show that both the scattered *P*- and *S*-waves of a single inclined fracture are strongly affected by

355

the FPD effects.

356

#### 4.2 Fractured reservoir model

357

In addition to a single fracture, we are more interested in the scattering behavior of discrete distributed fractures system. To

358

this end, we designed two fractured reservoir models containing a set of regularly distributed aligned horizontal fractures and

359

a set of randomly distributed aligned horizontal fractures, respectively, as illustrated in Fig. 6. There are 200 horizontal fractures

360

spread over a space of 200m, each extending 500m. The material properties of the fracture, background (yellow region) and

361

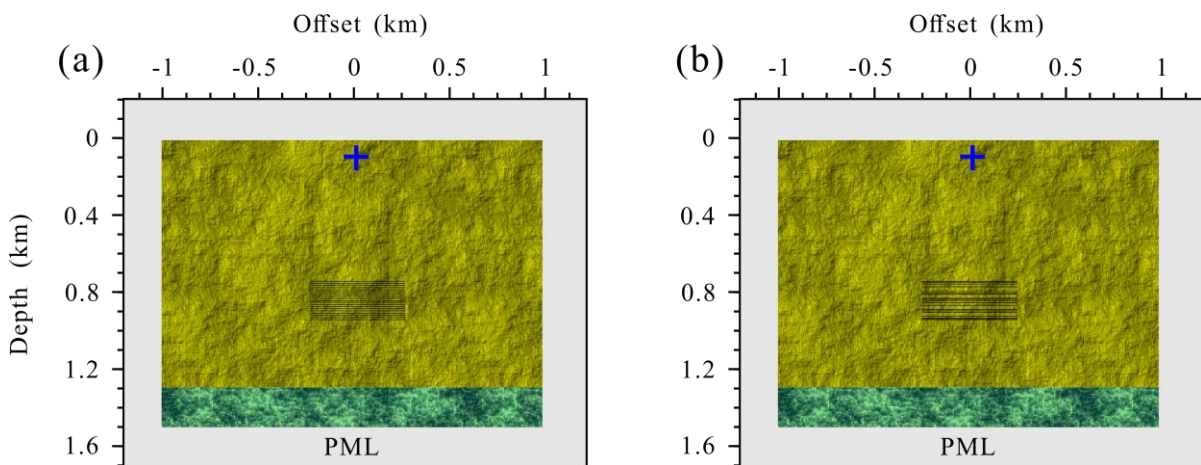

underlying (green region) formation are given in Table 1. The model size, grid interval and source location are the same as

362

those in the previous numerical examples. Through a set of aligned horizontal fracture structures is not practical in the actual

363

subsurface, it helps to illustrate the impact of FPD effects on the amplitude and phase of scattered waves of fractures.

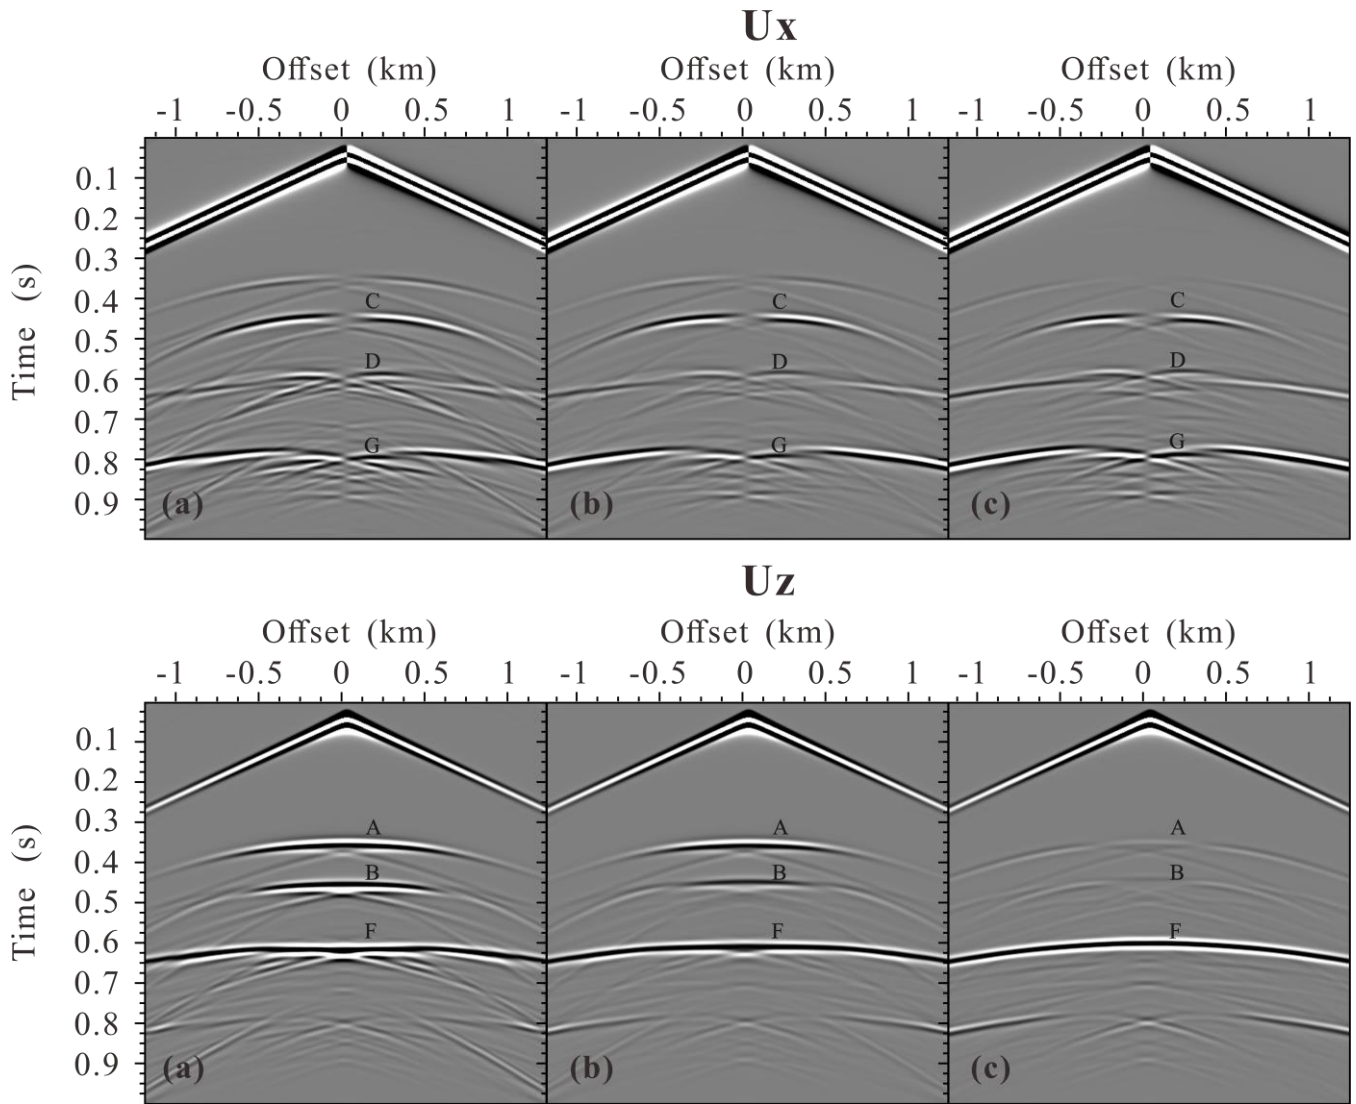

364

365

**Figure 6: Schematic diagram of the fractured reservoir model with a set of aligned horizontal fractures: (a)regular distribution (b)random distribution. The black segments present the fracture system. The extending of each fracture is 500m.**

**Figure 7: Seismogram components  $U_x$  and  $U_z$  of the fractured reservoir model with a set of regularly distributed aligned horizontal fractures calculated using (a) the LVLSM, (b) the VLSM, (c) the HVLSM. A, B are scattered  $P$ -wave from top and bottom, respectively, C and D are scattered converted shear  $S$ -wave from top and bottom, respectively, F and G are reflected  $P$ -wave and shear converted  $S$ -wave, respectively.**

372

373

**Figure 8: Time-frequency distributions of the middle trace for (b) the LVPLM, (c) the PLSM, and (d) the HVLSM cases in Fig. 7.**

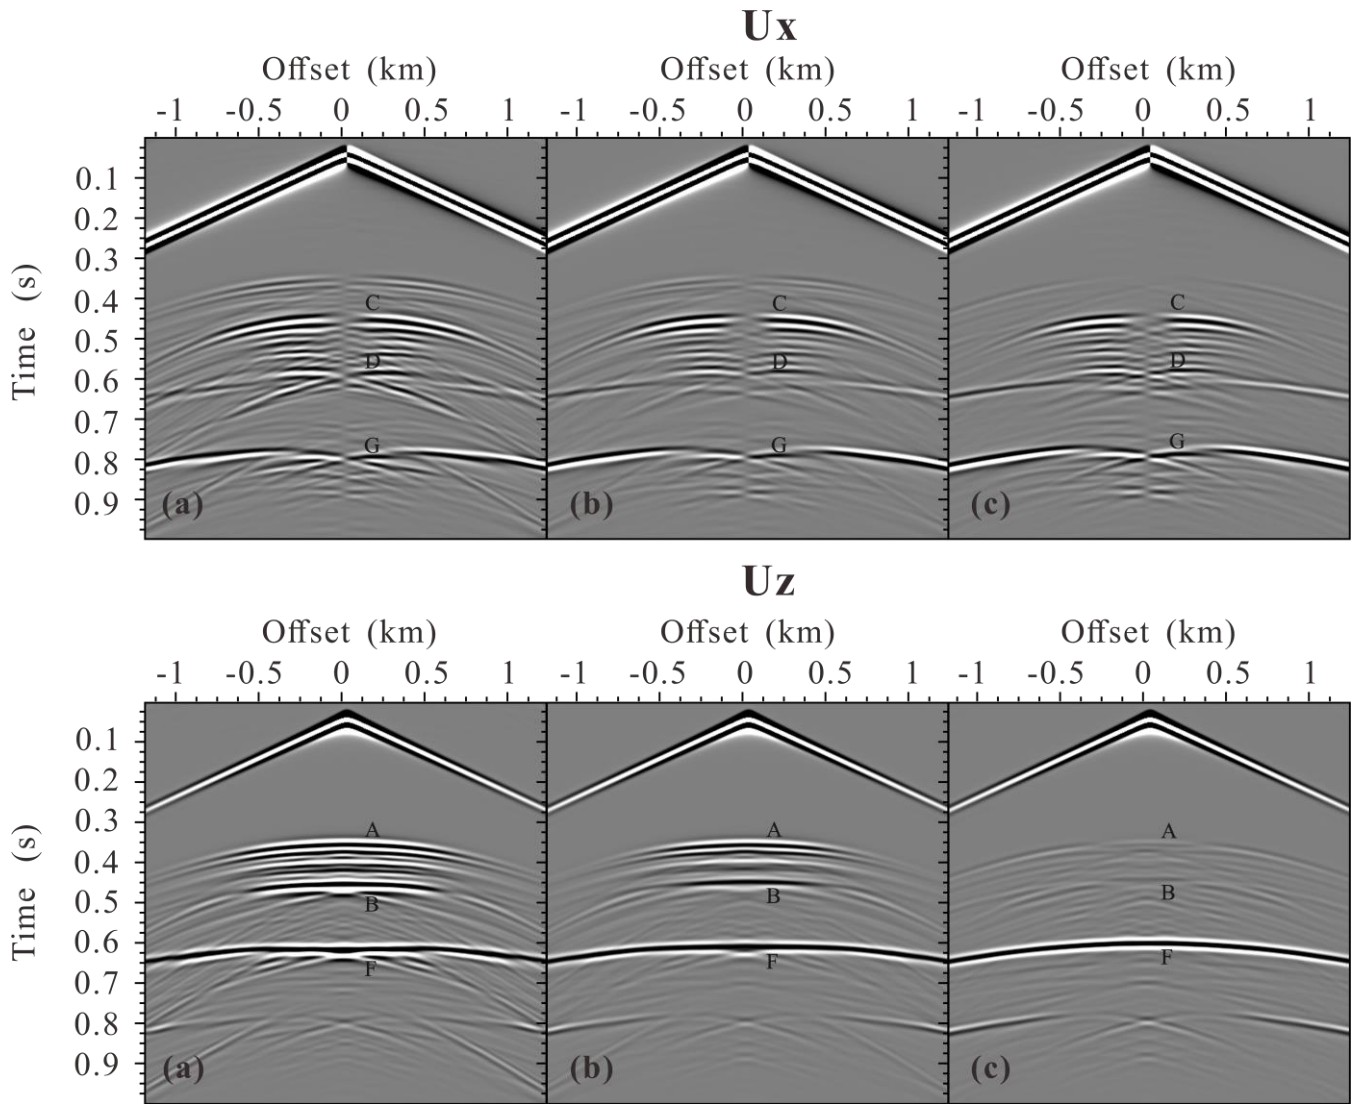

374

Figure 7 presents the seismograms of fractured reservoir model with a set of regular distributed aligned horizontal fractures.

375 The scattered compressional wave ( $S_{PP}$ ) and scattered converted wave ( $S_{PS}$ ) from the top and bottom of the fractured reservoir,  
376 the reflected compressional wave ( $R_{PP}$ ), converted wave ( $R_{PS}$ ) from the underlying formation can be clearly identified. Due to  
377 the regular distribution of aligned fracture, the fractured reservoir is equivalent to an anisotropic homogeneous media, and  
378 therefore the diffracted wave is generated only at the edges of the fractured reservoir. Similar to the single fracture case, the  
379 amplitude of the  $S_{PP}$  from the top and bottom of the fractured reservoir obtained by the HVLSM-based modeling is weakest  
380 (underestimated), that obtained by LVLSM-based modeling is strongest (overestimated), and that obtained by the VLSM-  
381 based modeling is intermediate. We notice that the  $S_{PP}$  amplitudes from the bottom of the fractured reservoir obtained by the  
382 LVLSM-based and HVLSM-based modeling are slightly smaller than those from the top, while the  $S_{PP}$  amplitude from the  
383 bottom obtained by the VLSM-based modeling is much smaller than that from the top. This is expected, since the VLSM-  
384 based modeling scheme can capture the wave attenuation and dispersion due to the FDP effects between the fracture system  
385 and background, while the LVLSM and HVLSM represent non-attenuated and non-dispersive elastic processes. Another  
386 evidence for attenuation is that the  $R_{PP}$  amplitudes of underlying formation calculated by the HVLSM-based and LVLSM-  
387 based modeling are almost equal, while the  $R_{PP}$  amplitude calculated by the VLSM-based modeling is much smaller. Figure 7  
388 also shows that the arrival times of  $S_{PP}$  from the bottom and  $R_{PP}$  from underlying formation obtained by the three modeling  
389 schemes are different.

390 To show the trend of frequency-dependent attenuation and dispersion, time-frequency distribution of the middle trace was  
391 computed for three modeling schemes. Figure 8 clearly shows that the frequency content and energy of the scattered and  
392 reflected waves calculated by VLSM tend to decrease strongly, while the frequency content and energy calculated by HVLSM  
393 and LVLSM remain steady. The impact of FPD effects on the  $S_{PS}$  and  $R_{PS}$  is similar to that of the  $S_{PP}$  and  $R_{PP}$ , but to a much  
394 weaker extent.

395 In addition to regularly distributed fractures, our proposed modeling scheme can also simulate the wave scattering of random  
396 distributed fractures. Figure 9 presents the seismograms of fractured reservoir model with a set of random distributed aligned  
397 horizontal fractures. Figure 10 presents the time-frequency distributions of the middle trace for three modeling schemes cases  
398 in Fig. 9. Due to the random distribution of aligned fracture, the fractured reservoir exhibits a stronger heterogeneity, resulting  
399 in more prevalent diffracted wave (coda wave) in Fig. 9 than in Fig. 7. Except for the diffracted wave, the scattered and  
400 reflected waves in the random distribution case is similar to those in the regular distribution case due to the FPD effect. The  
401 two fractured reservoir models suggest that the scattered waves from the bottom of the fractured reservoir are attenuated and  
402 dispersed by the FPD effects and the reflected waves can retain the relevant attenuation and dispersion information.

427

To validate the effectiveness of our proposed modeling scheme in a more practical underground fractured reservoir, we replace a set of aligned horizontal fractures in the original model with a set of aligned inclined fractures, as illustrated in Fig. 11. Figure 12 presents the seismograms of fractured reservoir model with a set of regular distributed aligned inclined fractures and Fig. 13 shows the time-frequency distributions of the middle trace for three modeling schemes. Figures 14 and 15 present the seismograms of fractured reservoir model with a set of random distributed aligned inclined fractures and the time-frequency distributions of the middle trace for three modeling schemes, respectively. All results of PLSM-based modeling capture the influence of FPD effects on the amplitude and phase of scattered waves, validating the effectiveness of our proposed modeling scheme. Figures 12 and 14 also show the different scattering characteristics of the randomly and regularly distributed incline fractures: many coda waves are generated by the randomly distributed fractures due to a stronger heterogeneity.

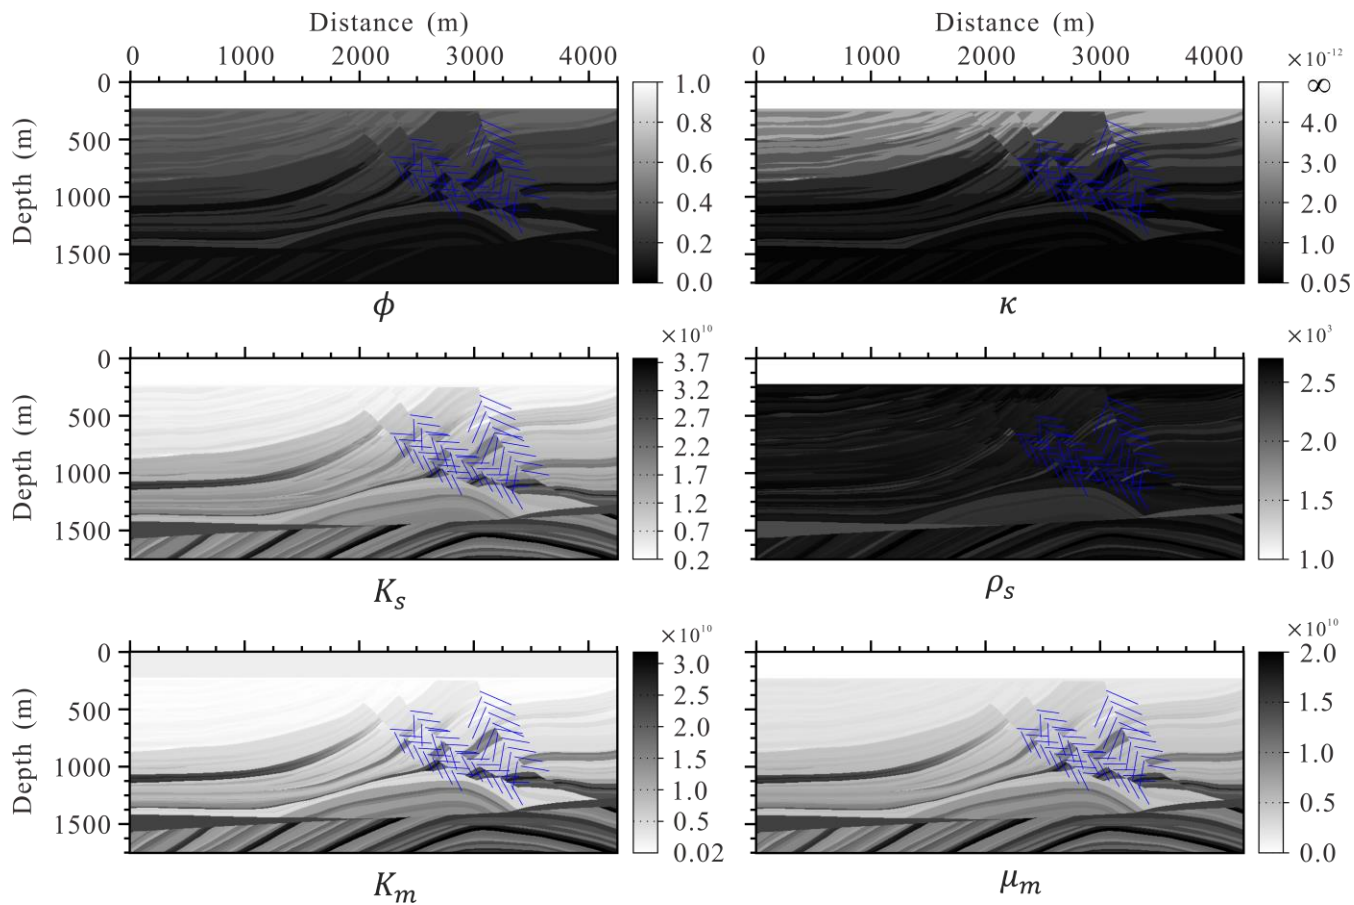

436

### 4.3 Modified Marmousi model

437

We test the proposed VLSM-based modeling scheme on a more complex modified Marmousi model. To modify the Marmousi model, we generate a porosity model, permeability model and discrete large-scale fracture system, and transform the original  $P$ -wave velocity and density into the fluid saturated bulk and shear modulus of the background by a constant Poisson's ratio 0.5, and finally obtain the grain bulk modulus, the frame bulk and shear modulus of the background through Gassmann equation and empirical formula ( $K_m = (1 - \phi)^{\frac{3}{1-\phi}} K_s$ ). The input physical properties and elastic modulus models of the modified Marmousi model are present in Fig. 11. The fluid density, bulk modulus and viscosity are the same as in Table 1. The model size is 4250m×1750m with grid interval 5m and a 100m thick PML boundary. The source is located at the surface (2125m, 0m). A Ricker wavelet with a central frequency of 25Hz is used as the temporal source excitation.

**Figure 17: Snapshots of the wavefields components  $U_x$  and  $U_z$  at 1000ms: (a) the original Marmousi model without fractures, (b) the modified Marmousi model with fractures and (c) the differences.**

450

451 **Figure 18: Seismogram components  $U_x$  and  $U_z$ : (a) the modified Marmousi model with fractures, (b) the original Marmousi model**  
 452 **without fractures and (c) the differences.**

453 Figure 17 shows the snapshots of displacement fields at 1000ms. The figure clearly shows the scattered P- and S-waves by the  
 454 discrete distributed large-scale fractures. The results with such a complex model clearly verify the numerical implementation  
 455 and the code. We also calculate the seismograms of the displacement shown in Fig. 18. The seismograms obtained by our  
 456 proposed modeling scheme present the scattered seismic waves by the discrete fractures.

## 457 **5 Conclusions**

458 In this work, we have developed a numerical modeling scheme including FPD effects for discrete distributed large-scale  
 459 fractures embedded in fluid saturated porous rock. To capture the FPD effects between the fractures and background, the  
 460 fractures are represented as Barbosa's VLSM with complex-valued and frequency-dependent fracture compliances. Using  
 461 Coates and Schoenberg's local effective medium theory and Barbosa's VLSM, we derive the effective anisotropic viscoelastic  
 462 compliances in each spatial discretized cell by superimposing the compliances of the background and the fractures. The  
 463 effective governing equations of each numerical cell are expressed by the derived effective compliances and discretized by

464 mixed-grid stencil FDFD. The proposed modeling scheme can be used to study the impact of mechanical and hydraulic of  
 465 fracture properties on seismic scattering. The main advantage of our proposed modeling scheme over poroelastic modeling  
 466 schemes is that the fractured domain can be modeled using a viscoelastic solid, while the rest of the domain can be modeled  
 467 using an elastic solid.

468 The scattered  $P$ -wave of a fluid saturated horizontal fracture calculated by VLSM-based modeling is strongly affected by the  
 469 FPD effects, while the scattered  $S$ -wave is less sensitive, which is consistent the result of PLSM-based modeling. However,  
 470 the LVLSM-based modeling overestimates the scattered  $P$ -wave and the HVLSM-based modeling underestimates the scattered  
 471  $P$ -wave. The numerical results valid that the proposed VLSM-based modeling can include the FPD effects and thus accurately  
 472 estimate the scattered wave of the horizontal fracture. The results of the fractured reservoir models show that the amplitudes  
 473 of the scattered waves from the top of the fractured reservoir are affected by the fluid stiffening effects due to the FPD effects.  
 474 The scattered waves from the bottom of the fractured reservoir are also attenuated and dispersed by the FPD effects in addition  
 475 to the fluid stiffening effects and the reflected waves can retain the relevant attenuation and dispersion information. Randomly  
 476 distributed fractures can also result in a different scattering characteristic than regularly distributed fractures, i.e. a large number  
 477 of coda waves are generated due to increased inhomogeneity. The results of the modified Marmousi model clearly show the  
 478 scattered waves by the discrete distributed large-scale fractures and verify the proposed numerical modeling scheme. The  
 479 proposed numerical modeling scheme is expected not only to improve the estimations of seismic wave scattering from discrete  
 480 distributed large-scale fractures but can also to improve migration quality and the estimation of fracture mechanical  
 481 characteristics in inversion.

## 482 **Appendix A: The coefficients related to spatial derivative operators**

483 We define coefficient vectors  $\mathbf{T}_k$  ( $k = 1, 2, 3, 4$ ) and the derivative operate vector  $\mathbf{D}(c)$  as

$$484 \quad \mathbf{T}_1 = \frac{1}{\xi_x \xi_x} [1 \ 0 \ 0 \ 0], \quad \mathbf{T}_2 = \frac{1}{\xi_x \xi_z} [0 \ 1 \ 0 \ 0], \quad \mathbf{T}_3 = \frac{1}{\xi_x \xi_z} [0 \ 0 \ 1 \ 0], \quad \mathbf{T}_4 = \frac{1}{\xi_z \xi_z} [0 \ 0 \ 0 \ 1], \quad (\text{A-1})$$

$$485 \quad \mathbf{D}(c) = [\partial_x (c \partial_x) \ \partial_x (c \partial_z) \ \partial_z (c \partial_x) \ \partial_z (c \partial_z)], \quad (\text{A-2})$$

486 where  $\xi_x$  and  $\xi_z$  are the PML damping function,  $c$  represents effective stiffness. Then, the expression of  $A_c, B_c, C_c, D_c$  are  
 487 written in matrix form:

$$488 \quad \begin{bmatrix} A_c \\ B_c \\ C_c \\ D_c \end{bmatrix} = \begin{bmatrix} \mathbf{D}(c_{11}) & \mathbf{D}(c_{15}) & \mathbf{D}(c_{15}) & \mathbf{D}(c_{55}) \\ \mathbf{D}(c_{15}) & \mathbf{D}(c_{55}) & \mathbf{D}(c_{13}) & \mathbf{D}(c_{35}) \\ \mathbf{D}(c_{15}) & \mathbf{D}(c_{13}) & \mathbf{D}(c_{55}) & \mathbf{D}(c_{35}) \\ \mathbf{D}(c_{55}) & \mathbf{D}(c_{35}) & \mathbf{D}(c_{35}) & \mathbf{D}(c_{33}) \end{bmatrix} \begin{bmatrix} \mathbf{T}_1 \\ \mathbf{T}_2 \\ \mathbf{T}_3 \\ \mathbf{T}_4 \end{bmatrix}. \quad (\text{A-3})$$

489 We formulate  $A_r, B_r, C_r, D_r$  in a similar way by defining the coefficient vectors  $\mathbf{T}'_k$  ( $k = 1, 2, 3, 4$ ) and  $\mathbf{D}'(c)$  as

490  $\mathbf{T}'_1 = \frac{1}{2\xi_x\xi_x} [1 \ 1 \ 1 \ 1]$ ,  $\mathbf{T}'_2 = \frac{1}{2\xi_x\xi_z} [-1 \ 1 \ -1 \ 1]$ ,  $\mathbf{T}'_3 = \frac{1}{2\xi_x\xi_z} [-1 \ -1 \ 1 \ 1]$ ,  $\mathbf{T}'_4 = \frac{1}{2\xi_z\xi_z} [1 \ -1 \ -1 \ 1]$ , (A-4)

491  $\mathbf{D}'(c) = [\partial_{x'}(c\partial_{x'}) \ \partial_{x'}(c\partial_{z'}) \ \partial_{z'}(c\partial_{x'}) \ \partial_{z'}(c\partial_{z'})]$ , (A-5)

492 The expression of  $A_r, B_r, C_r, D_r$  are written as

493 
$$\begin{bmatrix} A_r \\ B_r \\ C_r \\ D_r \end{bmatrix} = \begin{bmatrix} \mathbf{D}'(c_{11}) & \mathbf{D}'(c_{15}) & \mathbf{D}'(c_{15}) & \mathbf{D}'(c_{55}) \\ \mathbf{D}'(c_{15}) & \mathbf{D}'(c_{55}) & \mathbf{D}'(c_{13}) & \mathbf{D}'(c_{35}) \\ \mathbf{D}'(c_{15}) & \mathbf{D}'(c_{13}) & \mathbf{D}'(c_{55}) & \mathbf{D}'(c_{35}) \\ \mathbf{D}'(c_{55}) & \mathbf{D}'(c_{35}) & \mathbf{D}'(c_{35}) & \mathbf{D}'(c_{33}) \end{bmatrix} \begin{bmatrix} \mathbf{T}'_1 \\ \mathbf{T}'_2 \\ \mathbf{T}'_3 \\ \mathbf{T}'_4 \end{bmatrix}. \quad (\text{A-6})$$

494 **Appendix B: Parsimonious staggered-grid stencil**

495 The nine coefficients of the CS stencil for the submatrix  $\mathbf{A}_c$  of Eq. (36):

496  $A_{c \ i+1,j} = \frac{c_{11 \ i+0.5,j}}{\Delta^2 \xi_x \xi_x \xi_{x \ i+0.5}}, A_{c \ i-1,j} = \frac{c_{11 \ i-0.5,j}}{\Delta^2 \xi_x \xi_x \xi_{x \ i-0.5}}, A_{c \ i,j+1} = \frac{c_{55 \ i,j+0.5}}{\Delta^2 \xi_z \xi_z \xi_{z \ j+0.5}}, A_{c \ i,j-1} = \frac{c_{55 \ i,j-0.5}}{\Delta^2 \xi_z \xi_z \xi_{z \ j-0.5}},$

497  $A_{c \ i,j} = -\frac{c_{11 \ i+0.5,j}}{\Delta^2 \xi_x \xi_x \xi_{x \ i+0.5}} - \frac{c_{11 \ i-0.5,j}}{\Delta^2 \xi_x \xi_x \xi_{x \ i-0.5}} - \frac{c_{55 \ i,j+0.5}}{\Delta^2 \xi_z \xi_z \xi_{z \ j+0.5}} - \frac{c_{55 \ i,j-0.5}}{\Delta^2 \xi_z \xi_z \xi_{z \ j-0.5}}, A_{c \ i+1,j+1} = \frac{c_{15 \ i+1,j} + c_{15 \ i,j+1}}{4\Delta^2 \xi_x \xi_x \xi_z \xi_z},$

498  $A_{c \ i+1,j-1} = -\frac{c_{15 \ i+1,j} + c_{15 \ i,j-1}}{4\Delta^2 \xi_x \xi_x \xi_z \xi_z}, A_{c \ i-1,j+1} = -\frac{c_{15 \ i-1,j} + c_{15 \ i,j+1}}{4\Delta^2 \xi_x \xi_x \xi_z \xi_z}, A_{c \ i-1,j-1} = \frac{c_{15 \ i-1,j} + c_{15 \ i,j-1}}{4\Delta^2 \xi_x \xi_x \xi_z \xi_z}. \quad (\text{B-1})$

499 The nine coefficients of the RS stencil for the submatrix  $\mathbf{A}_r$  of Eq. (36):

500  $A_{r \ i+1,j} = \frac{c_{11 \ i+0.5,j-0.5} - c_{55 \ i+0.5,j-0.5}}{4\Delta^2 \xi_x \xi_x \xi_{z \ j-0.5}} + \frac{c_{11 \ i+0.5,j+0.5} - c_{55 \ i+0.5,j+0.5}}{4\Delta^2 \xi_z \xi_z \xi_{x \ i+0.5}}, A_{r \ i-1,j} = \frac{c_{11 \ i-0.5,j+0.5} - c_{55 \ i-0.5,j+0.5}}{4\Delta^2 \xi_x \xi_x \xi_{z \ j+0.5}} + \frac{c_{11 \ i-0.5,j-0.5} - c_{55 \ i-0.5,j-0.5}}{4\Delta^2 \xi_z \xi_z \xi_{x \ i-0.5}},$

501  $A_{r \ i,j+1} = \frac{c_{55 \ i-0.5,j+0.5} - c_{11 \ i-0.5,j+0.5}}{4\Delta^2 \xi_x \xi_x \xi_{z \ j+0.5}} + \frac{c_{55 \ i+0.5,j+0.5} - c_{11 \ i+0.5,j+0.5}}{4\Delta^2 \xi_z \xi_z \xi_{x \ i+0.5}}, A_{r \ i,j-1} = \frac{c_{55 \ i+0.5,j-0.5} - c_{11 \ i+0.5,j-0.5}}{4\Delta^2 \xi_x \xi_x \xi_{z \ j-0.5}} + \frac{c_{55 \ i-0.5,j-0.5} - c_{11 \ i-0.5,j-0.5}}{4\Delta^2 \xi_z \xi_z \xi_{x \ i-0.5}},$

502  $A_{r \ i,j} = -\frac{c_{11 \ i+0.5,j-0.5} - 2c_{15 \ i+0.5,j-0.5} + c_{55 \ i+0.5,j-0.5}}{4\Delta^2 \xi_x \xi_x \xi_{x \ i+0.5}} - \frac{c_{11 \ i-0.5,j+0.5} - 2c_{15 \ i-0.5,j+0.5} + c_{55 \ i-0.5,j+0.5}}{4\Delta^2 \xi_x \xi_x \xi_{x \ i-0.5}} - \frac{c_{11 \ i+0.5,j+0.5} + 2c_{15 \ i+0.5,j+0.5} + c_{55 \ i+0.5,j+0.5}}{4\Delta^2 \xi_z \xi_z \xi_{z \ j+0.5}} - \frac{c_{11 \ i-0.5,j-0.5} + 2c_{15 \ i-0.5,j-0.5} + c_{55 \ i-0.5,j-0.5}}{4\Delta^2 \xi_z \xi_z \xi_{z \ j-0.5}}$

503  $A_{r \ i+1,j+1} = \frac{c_{11 \ i+0.5,j+0.5} + 2c_{15 \ i+0.5,j+0.5} + c_{55 \ i+0.5,j+0.5}}{4\Delta^2 \xi_z \xi_z \xi_{z \ j+0.5}}, A_{r \ i+1,j-1} = \frac{c_{11 \ i+0.5,j-0.5} - 2c_{15 \ i+0.5,j-0.5} + c_{55 \ i+0.5,j-0.5}}{4\Delta^2 \xi_x \xi_x \xi_{x \ i+0.5}},$

504  $A_{r \ i-1,j+1} = \frac{c_{11 \ i-0.5,j+0.5} - 2c_{15 \ i-0.5,j+0.5} + c_{55 \ i-0.5,j+0.5}}{4\Delta^2 \xi_x \xi_x \xi_{x \ i-0.5}}, A_{r \ i-1,j-1} = \frac{c_{11 \ i-0.5,j-0.5} + 2c_{15 \ i-0.5,j-0.5} + c_{55 \ i-0.5,j-0.5}}{4\Delta^2 \xi_z \xi_z \xi_{z \ j-0.5}}. \quad (\text{B-2})$

505 The coefficients of the submatrices  $\mathbf{B}_c, \mathbf{C}_c, \mathbf{D}_c$  and  $\mathbf{B}_r, \mathbf{C}_r, \mathbf{D}_r$  can be inferred easily from those of submatrix  $\mathbf{A}_c$  and  $\mathbf{A}_r$ ,  
506 respectively.

507 **Author contributions**

508 YQ, XC, and XL planned the campaign; YQ and QZ wrote the numerical simulation programs; YQ, XC, and CF analyzed the  
509 numerical cases; YQ and XC wrote the manuscript draft; YQ, XC, QZ, XL and CF reviewed and edited the manuscript.

510 **Competing interests**

511 The authors declare that they have no conflict of interest.
