8 **Abstract.** This work assesses the effectiveness of sample preservation techniques for measurements of pH_T (total scale), total
9 dissolved inorganic carbon (DIC_T), and total alkalinity (A_T) in organic-rich estuarine waters. Using HgCl₂-treated and untreated
10 water samples, measurements of these carbonate system parameters were examined over a period of three months. Over this
11 duration, continued respiration of dissolved organic matter (DOM) in untreated samples created large discrepancies in DIC_T
12 concentrations, while DIC_T was effectively constant in treated samples. Changes in A_T were observed for both treated and
13 untreated samples, with treated samples showing the greatest variation. In response to changing A_T/DIC_T ratios, pH_T changes
14 were observed in both treated and untreated samples but were relatively small in treated samples. Improved accuracy of results
15 in organic-rich estuarine waters that reflect the in situ carbonate system characteristics of the samples at the time of collection
16 can be achieved when samples obtained for DIC_T and A_T analysis are collected and stored separately. Accurate analyses of
17 DIC_T can be obtained by filtration and preservation with HgCl₂. Accuracy of A_T analyses can be improved by filtration and
18 storage in polypropylene bottles at 4°C without adding HgCl₂. Quality of pH_T measurements can be improved by prompt
19 analysis in the field and, if this cannot be accomplished, then samples can be preserved with HgCl₂ and measured in the
20 laboratory within one week.

21 **1. Introduction and background**

22 Accurate measurements of carbonate system parameters, including pH_T (total scale), total dissolved inorganic carbon (DIC_T),
23 total alkalinity (A_T) and carbon dioxide fugacity $f(\text{CO}_2)$, in coastal and estuarine environments are essential for understanding
24 the mechanisms controlling ecosystem health and its resources (Doney, 2006; Cai et al., 2021). Characterization of the
25 carbonate system is fundamental for a quantitative understanding of buffer intensity, indicating the extent to which pH is
26 maintained within the limited range required for optimal functioning of biological processes (Butler, 1991; Pilson, 2012;
27 Stumm and Morgan, 2012). Measurements of in situ pH_T along with either DIC_T or A_T are essential, as well, for calculating in
28 situ saturation states (Byrne, 2014) relevant to calcareous organisms. Due to the substantial complexity of low salinity ($S <$
29 20) environments with high organic matter content, and their susceptibility to rapid changes from freshwater sources, these
30 ecosystems are poorly understood relative to pelagic environments (Hunt et al., 2011; Song et al., 2020).

31 Carbonate system parameters are typically preserved in the field for subsequent analysis in a suitable laboratory. Following a
32 geochemical investigation of four rivers that discharge into Tampa Bay, Florida USA, where large seasonal variations were
33 observed (Moore, 2022), a quantitative assessment of sample preservation techniques was conducted over a three-month
34 period. Time series measurements of key carbonate system parameters were assessed using both HgCl₂-treated and untreated
35 water samples. Although sample preservation techniques have been extensively evaluated in some environments (Wong, 1970;
36 Dickson, 2007), studies in organic rich waters are rare (Mos et al., 2021). In the investigation of Mos et al. (2021) the
37 effectiveness of diverse preservation and storage methods on the total alkalinity (A_T) of aqueous environmental samples
38 (seawater, estuarine water, freshwater, and groundwater) were examined over a period of six months. Our investigation extends
39 the work of Mos et al. (2021) by documenting daily-to-weekly changes in three carbonate system parameters pH_T (i.e., -
40 log[H⁺]_T), DIC_T, and A_T for organic-rich estuarine samples preserved with and without HgCl₂.

41 In addition to addressing sample stability issues, these measurements allow assessment of how sample-storage/preservation
42 influence the final concentrations of directly measured parameters (e.g., A_T) and parameters that are calculated from DIC_T and
43 pH_T. Investigations of the internal consistency of carbonate system measurements in high salinity marine waters (direct
44 measurements vs. calculations) have been conducted over several decades. The internal consistency between measured and
45 calculated carbonate system parameters has improved over time due to improvements in both measurement procedures and
46 refinements of the models that are used in carbonate system calculations. For high salinity marine data sets, a variety of
47 investigations have shown that differences between measured A_T and A_T calculated from pH_T and DIC_T are currently on the
48 order of 3 to 4 μmol kg⁻¹. This difference between measured and calculated A_T is similar to uncertainties typically observed
49 for A_T measurements (Millero et al., 1993; Patsavas et al., 2015; Fong and Dickson, 2019). Prior assessments of carbonate
50 system parameters showed that internal consistency (i.e., measurements and calculations of A_T) have been limited to the range
51 of salinity (S) within which sulfonephthalein pH indicators, such as meta-Cresol Purple (mCP), have been carefully calibrated
52 (20 ≤ S ≤ 40). Until the recent publications of Douglas and Byrne (2017) and Müller and Rehder (2018), carbonate system
53 internal consistency evaluations using modern pH measurement techniques in estuarine and fresh waters have not been
54 possible. In addition to providing a general assessment of the use of HgCl₂ as a preservative for measurements of carbonate
55 system parameters, our investigation provides perspectives on the influence of Hg^{II} on CO₂ internal consistency calculations
56 under estuarine conditions.

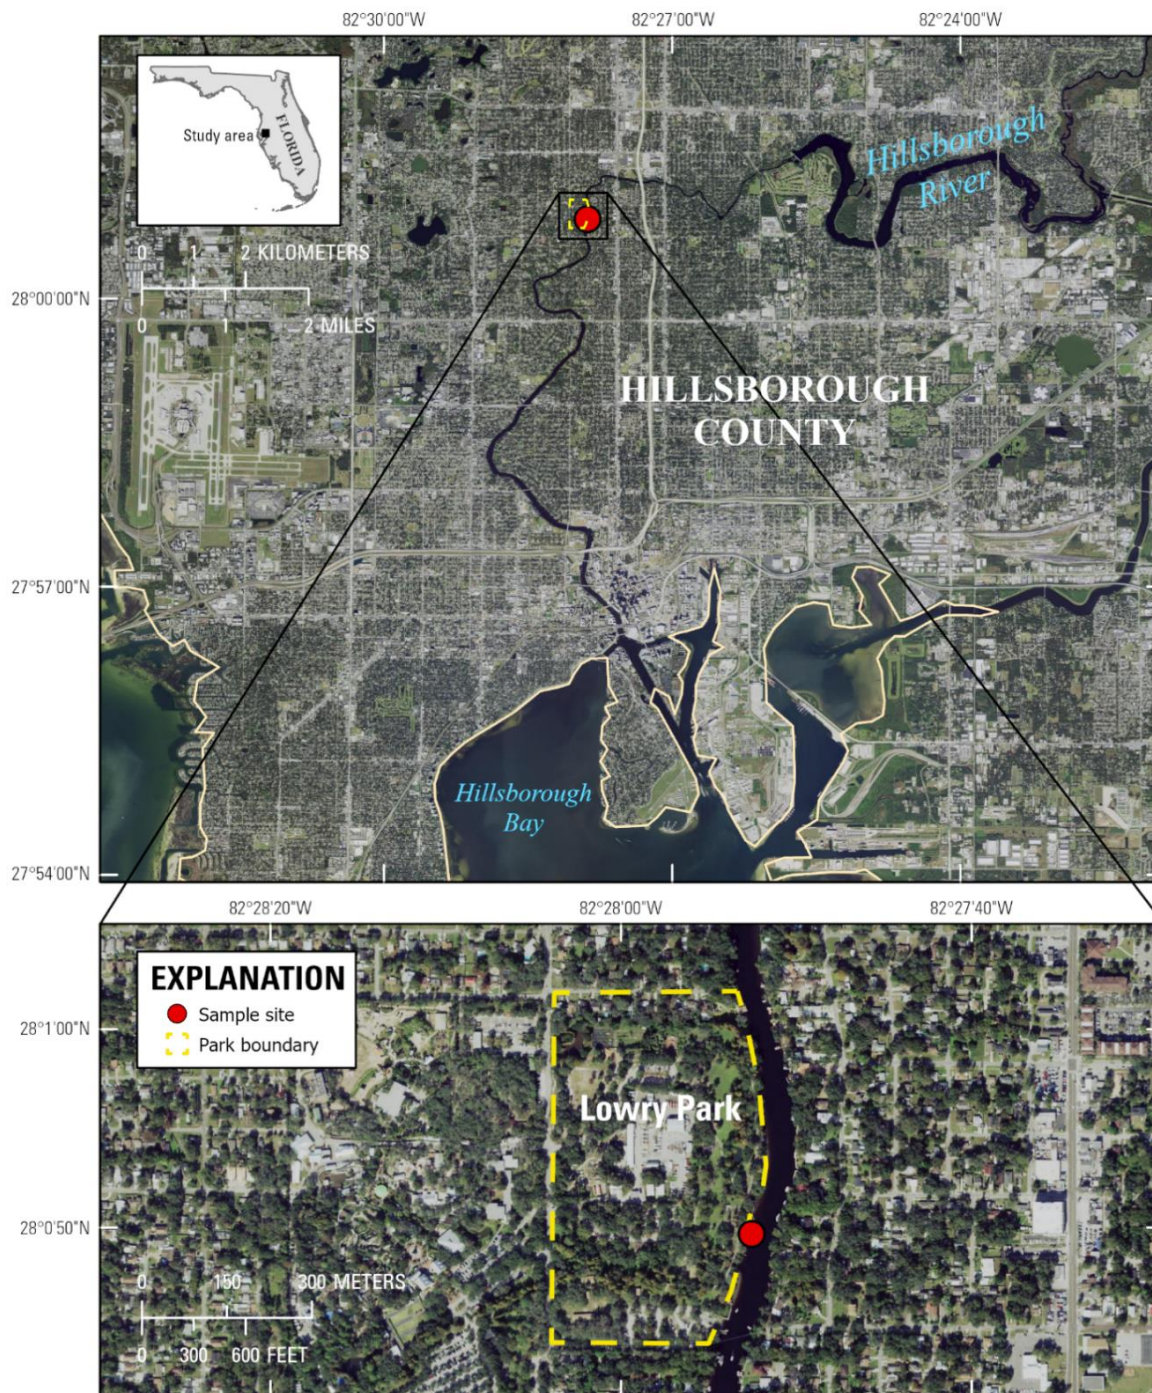

57 **2. Methods and materials**

58 **2.1 Sample collection**

59 Hillsborough River water samples were collected on January 26th, 2021, from the boardwalk of the Lowry Park Riverside Trail
60 (28.0138 N, 82.4646 W) (Fig. 1). Water temperature and salinity were measured using a Sea-Bird Scientific Micro
61 Thermosalinograph, and then two 30-L Niskin bottles were used to simultaneously collect surface river water. Water from
62 each Niskin was filtered, promptly analyzed spectrophotometrically to establish initial pH_T and then preserved for analysis of

63 major inorganic nutrients. The filtration was performed under positive pressure using a 12V peristaltic pump (GeoTech) and
64 peristaltic tubing (Masterflex). The tubing was connected to a 142 mm diameter acrylic filter housing (GeoTech) that contained
65 a 0.45 μm cellulose nitrate filter (GeoTech). Water collected for analysis of major inorganic nutrients was additionally filtered
66 using a sterile 0.22 μm pressure filter (Sterivex) attached by Luer lock to a 60 mL syringe and then stored in a 30 mL acid
67 washed high density polyethylene bottle (Nalgene). Once each nutrient sample bottle was sealed, the bottle was stored on ice,
68 transported to the laboratory, and then frozen until analysis (Dore et al. 1996). Next, water samples from each Niskin were
69 simultaneously filtered into a total of 70 borosilicate glass bottles (300 mL total volume) using the methods described by
70 Dickson et al. (2007). Water samples from the first Niskin (i.e., 35 samples) were treated with 100 μL of 6.5% HgCl_2
71 (LabChem). Water samples from the second Niskin (i.e., 35 samples) were not treated. Both sets of bottles were promptly
72 sealed with Apiezon M grease for transport. After these samples were collected and processed, additional water from each
73 Niskin was filtered and analyzed spectrophotometrically to determine a final pH_T , and then sampled for analysis of major
74 inorganic nutrients. All water samples were then transported to the U.S. Geological Survey Carbon Laboratory in St Petersburg,
75 Florida where the borosilicate bottles were stored in the dark at room temperature (25°C) and sequentially analyzed, beginning
76 hours after collection, over a period of three months for pH_T (total scale), total dissolved inorganic carbon (DIC_T), and total
77 alkalinity (A_T).

80 Bay in Tampa Bay (upper) and to Lowry Park (lower).

81

82 2.2 Sample analysis

83 2.2.1 Field analysis (pH_T)

84 Recent advances in the characterization of spectrophotometric indicator dyes and pK_{2e2} models for spectrophotometric pH_T
85 and A_T analysis have enabled analysis in waters over a full river-to-sea range of salinity ($0 \leq S \leq 40$) and temperature ($0 \leq T \leq$
86 40) (pH: Douglas and Byrne, 2017, Rehder and Müller, 2018; A_T: Hudson-Heck et al., 2021). Spectrophotometric pH_T field
87 analyses were performed using the methods of Clayton and Byrne (1993). Each filtered pH_T sample was collected in a 10 cm
88 pathlength cylindrical glass cell and placed within an Ocean Optics CUV-UV-10 cuvette holder connected to an Ocean Optics
89 LS-1 Tungsten light source and an Ocean Optics USB2000 spectrometer. Two 10 µL additions of purified M-cresol purple
90 (mCP) indicator dye (Liu et al., 2011) were added with a Gilmont GS-1100 Micrometer Syringe, and pH_T was corrected for
91 any indicator dye perturbation by back correction from the second dye addition (Clayton and Byrne, 1993). Absorbance
92 measurements were made using the Ocean Optics software package OOIBase 32. The measurement temperature for these
93 analyses (approximately 26.5 °C) was determined using a Fluke 51 II Handheld Digital Probe Thermometer. The temperatures
94 provided by this probe were in good agreement with those obtained with a Hewlett Packard 2804A quartz thermometer ($\Delta T \approx$
95 0.125 ± 0.024 °C). Sample pH_T was calculated on the total scale using the algorithm of Müller and Rehder (2018). Each pH_T
96 was temperature corrected to 20° C in CO₂sys.m (van Heuven et al., 2011) using the K1K2 constants of Waters, Millero, &
97 Woesley (2014), the KSO₄ constants of Dickson (1990), and the total boron to salinity ratio (B_T/S) of Lee et al. (2010).

98 2.2.2 Laboratory analysis of pH_T, DIC_T, and A_T and nutrients

99 Treated and untreated water samples were analyzed over a period of three months. Samples were first analyzed within a few
100 hours of collection and subsequently analyzed every other day for 7 days. After the first week, samples were then analyzed
101 weekly for the duration of the experiment. The measurement methods used over this three-month period were identical for
102 each type of analysis, and samples were analyzed in the order they were initially collected. On each day of analysis four sample
103 bottles, two treated samples and two untreated samples, were analyzed in the following order: pH_T, DIC_T and A_T.

104 Spectrophotometric pH_T analysis in the laboratory was performed using the methods of Clayton and Byrne (1993). Sample
105 water was poured from the borosilicate bottle into two 10 cm pathlength cylindrical glass cells. Each cylindrical cell was placed
106 in a temperature controlled Ocean Optics CUV-UV-10 cuvette holder connected to an Ocean Optics LS-1 Tungsten light
107 source and Ocean Optics USB2000 spectrometer. pH_T analyses in the laboratory were identical to those used for pH_T
108 measurements in the field.

109 Immediately after the pH_T measurements, water samples for duplicate total dissolved inorganic carbon (DIC_T) analyses were
110 withdrawn from the same sample bottle. Using a 60 mL syringe connected to a 3 way Luer lock valve and stopper to minimize
111 gas exchange, two 20 mL samples were drawn from each bottle. Analyses were performed with a CM5017 CO₂ carbon
112 coulometer coupled to a CM5330 acidification module (UIC, Inc.) following the methods described by Dickson and Goyet

113 (1994). Sample weights were determined using a Denver Instruments PI-214 analytical balance (± 0.1 mg). Injected sample
114 mass was determined as the difference in syringe weights before and after each sample was injected through a septum into the
115 stripping chamber of the acidification module. Samples were acidified with ~ 10 mL of 8.5% H_3PO_4 . Analytical grade N_2 was
116 used as the carrier gas for CO_2 from acidified samples to the coulometer. The titration endpoint was determined by the
117 coulometer, and DIC_T was calculated using software from UIC, Inc. Accuracy and precision was determined from analysis of
118 certified reference materials (CRM) obtained from Andrew Dickson at the Scripps Institution of Oceanography (Dickson,
119 2010). Repeat measurements ($N = 51$) of CRM Batch 189 and CRM Batch 183 yielded precisions of ± 1.09 and $\pm 0.71 \mu\text{mol}$
120 kg^{-1} respectively (standard deviation of each average daily CRM analysis) and an accuracy of $1.43 \pm 1.04 \mu\text{mol kg}^{-1}$ (average
121 of the absolute value of the difference between each measured CRM and the reported batch concentration).

122 After completion of the DIC_T analyses, measurements of total alkalinity (A_T) were performed using the spectrophotometric
123 methods of Yao and Byrne (1998) and Liu et al. (2015). Water sample mass (~ 100 g) and masses of added acid were determined
124 gravimetrically using a Denver Instruments PI-214 analytical balance (± 0.1 mg). Water samples were analyzed in an open top
125 square glass cell (Hellma Cells, Inc.) placed within a custom plastic frame connected to an Ocean Optics LS-1 Tungsten light
126 source and Ocean Optics USB2000 spectrometer. Bromocresol purple (BCP) indicator dye (4 mM stock solution) was
127 administered by pipette (100 μL), and the sample was titrated using 0.100 ± 0.0001 N standardized HCl (Lab Chem Inc.) added
128 with a plastic 10 mL syringe fitted with a Teflon syringe needle. Absorbance measurements were made using the Ocean Optics
129 software package OOIBase 32 (Landis, 2005). The pH_T of each solution was measured throughout the titration to an endpoint
130 near pH_T 4.3. The total weight of added acid was determined from the difference in the syringe weight before and after acid
131 addition. At the end of each titration, the solution was purged of CO_2 with a stream of N_2 gas that had been pre saturated with
132 H_2O . After purging, final absorbance measurements were made, and solution temperature was determined using a Fluke 51 II
133 Handheld Digital Probe Thermometer. A_T was calculated using the BCP equations of Hudson-Heck et al. (2021). Accuracy
134 and precision were determined from analysis of Andrew Dickson's certified reference materials (CRM) (Dickson, 2010).
135 Repeat measurements ($N = 33$) of CRM Batches 183, 186, and 189 yielded precisions of $\pm 0.93 \mu\text{mol kg}^{-1}$, $\pm 0.76 \mu\text{mol kg}^{-1}$,
136 and $\pm 1.39 \mu\text{mol kg}^{-1}$ respectively, and an accuracy of $0.77 \pm 0.93 \mu\text{mol kg}^{-1}$.

137 Internal consistency calculations of A_T , from measured pH_T and DIC_T were performed in $\text{CO}_2\text{sys.m}$ (van Heuven et al., 2011)
138 using the K_1K_2 constants of Waters, Millero, & Woosley (2014), the KSO_4 constants of Dickson (1990), and the B_T/S constant
139 of Lee et al. (2010). Significance tests with 95% confidence levels were performed in Microsoft Excel using the *Data Analysis*
140 *Regression* tool.

141 Nutrient analyses were performed at the University of Tampa. Samples were analyzed for inorganic nitrogen ($\text{NO}_3^- + \text{NO}_2^-$),
142 inorganic phosphate ($\text{H}_2\text{PO}_4^- + \text{HPO}_4^{2-} + \text{PO}_4^{3-}$), ammonia ($\text{NH}_3 + \text{NH}_4^+$), and silica ($\text{SiO}(\text{OH})_3^- + \text{Si}(\text{OH})_4$) using the methods
143 of Gordon et al. (1993).

144

145 **3. Results and discussion**

146 Clear distinctions were observed over three months between untreated and treated (HgCl_2) water samples for all three measured
 147 carbonate system parameters: pH_T , DIC_T , and A_T . From the first analyses $\text{DIC}_T(\text{untreated})$ was greater than $\text{DIC}_T(\text{treated})$, and
 148 the difference between $\text{DIC}_T(\text{untreated})$ and $\text{DIC}_T(\text{treated})$ increased throughout the 91 days of analysis (Fig. 2). The DIC_T of
 149 HgCl_2 -treated samples was essentially constant throughout the duration of the experiment ($3,095.5 \pm 3.2$) while the DIC_T of
 150 untreated samples increased by approximately $37 \mu\text{mol kg}^{-1}$ over 91 days. The regression of DIC_T vs time for the untreated
 151 samples ($\text{DIC}_T = 3,100.2 + (0.4088 \pm 0.04)x$) ($p < 0.0001$) (Fig. 2) indicated that DIC_T increased by approximately $0.41 \mu\text{mol}$
 152 kg^{-1} per day over the course of the experiment (note that anomalous results obtained on day 2 for both untreated and HgCl_2 -
 153 treated samples are not included in the figure but are shown in the associated data release, Moore et al. (2022),
 154 <https://doi.org/10.5066/P9J9IYFD>).

155 **Figure 2. Average (AVG) measured DIC_T in treated (HgCl_2) and untreated samples over time where error bars are the standard**
 156 **deviation of the average from each day of analysis. Dotted lines represent a best fit linear trendline for the data.**
 157

158 Respiration of dissolved organic matter (DOM) dramatically increased DIC_T in the untreated samples (Fig. 2). Results for the
 159 treated DIC_T samples show that the addition of HgCl_2 was effective at curtailing respiration as treated samples were invariant
 160 over a period of three months. It is noted that, at the inception of the experiment, there was a small DIC_T difference between
 161 the two sample types (treated and untreated) (Fig. 2); the calculated DIC_T intercepts differ by about $5.2 \pm 2.4 \mu\text{mol kg}^{-1}$. This
 162 $5.2 \mu\text{mol kg}^{-1}$ difference may be a real sampling artifact (i.e., a small difference between samples collected simultaneously at
 163 the same location); the difference is similar to the 1σ uncertainty ($\pm 2.4 \mu\text{mol kg}^{-1}$) in the calculated difference between the
 164 two intercepts.

165 A_T results also show a large difference between $HgCl_2$ -treated and untreated samples (Fig. 3). Unlike DIC_T observations,
 166 however, a large difference between the $HgCl_2$ -treated and untreated samples was observed at the inception of the measurement
 167 period. Furthermore, in contrast to the near constancy of DIC_T for the $HgCl_2$ -treated samples, the A_T of the untreated samples
 168 was approximately constant ($p < 0.01$), while the A_T of treated samples decreased by approximately $26 \mu mol kg^{-1}$ over the
 169 course of the experiment ($p < 0.001$). Overall, at the beginning of the measurement period the A_T of the $HgCl_2$ -treated samples
 170 was lower than the A_T of the untreated samples by more than $26 \mu mol kg^{-1}$, and this difference grew to more than $45 \mu mol$
 171 kg^{-1} at the end of the three-month period of measurements.

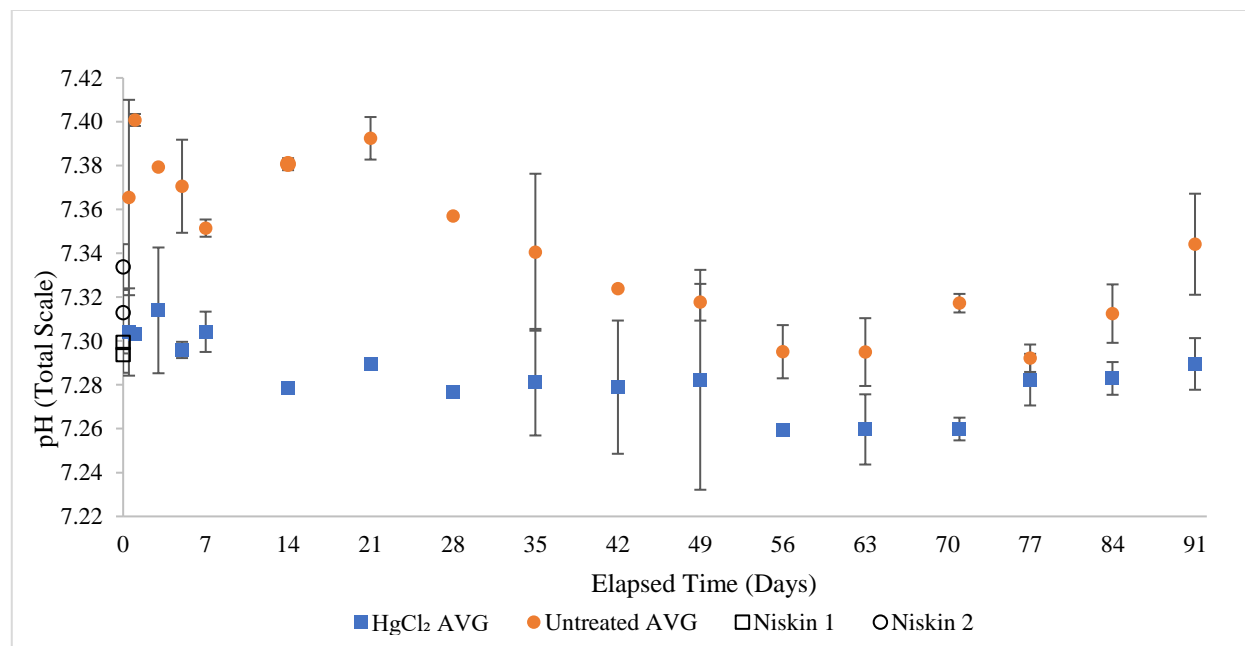

172 **Figure 3. Average (AVG) measured A_T in treated ($HgCl_2$) and untreated samples over time where error bars are the standard**
 173 **deviation of the average from each day of analysis. Dotted lines represent a best fit linear trendline for the data.**
 174

175 Respiration of DOM caused A_T to decrease through time in the untreated samples (Fig. 3). Consistent with the modern revised
 176 Redfield equation ($P_T:N_T:C_T = 1:16:124$) (Takahashi et al., 1985; Broecker et al., 1985; Anderson and Sarmiento, 1994;
 177 Körtzinger et al., 2001), respiration of DOM produces an increase in DIC_T that is about 7.3 times larger than the accompanying
 178 decrease in A_T . Based on the $37 \mu mol kg^{-1}$ increase in DIC_T over 91 days, and the expected factor of 7.3 difference between
 179 changes in DIC_T and changes in A_T (i.e., $\Delta DIC_T / \Delta A_T = 7.3$), the expected decrease in A_T is somewhat smaller than the observed
 180 decrease. However, considering the uncertainties in slope in Fig. 2 and Fig. 3 for the untreated samples, the expected change
 181 in A_T calculated as $\Delta DIC_T / 7.3$ (i.e., $5.1 \pm 0.5 \mu mol kg^{-1}$) is reasonably consistent with the observed change in A_T (7.1 ± 2.4
 182 $\mu mol kg^{-1}$).

183 Results for $pH(20^\circ C)_T$ of prompt untreated pH_T measurements made in the field (shown as open markers at time zero) and
 184 laboratory measurements (solid markers) made after collection of field measurements are shown in Fig. 4. As was observed

185 for DIC_T and A_T , a clear difference was observed between treated and untreated samples. Consistent with the decreasing A_T
 186 and the substantially increasing DIC_T for the untreated samples, pH_T (untreated) decreased from an average of 7.377 ± 0.022
 187 for days 1 through 21 to 7.317 ± 0.024 for days 28 through 91. The pH_T changes of the treated samples were smaller than those
 188 of the untreated samples, averaging 7.302 ± 0.018 for days 1 through 21 and 7.275 ± 0.020 for days 28 through 91.

189 **Figure 4. Average (AVG) measured pH_T from the field, notated as Niskin 1 (treated) and Niskin 2 (untreated), and from the**
 190 **laboratory, notated as HgCl₂ and Untreated, over time where error bars are the standard deviation of the average from each day of**
 191 **analysis. Note the first field measurements occurred several minutes before sample bottle preservation (i.e., the beginning of elapsed**
 192 **time axis), while the second and final field measurements occurred after sample bottle preservation. The time between the first and**
 193 **second field measurements was approximately 45 minutes. The first laboratory measurements occurred approximately 2.25 hours**
 194 **after the final field measurement.**
 195

196 For untreated samples, Fig. 4 shows the expected temporal decrease in pH_T that results from increasing DIC_T and decreasing
 197 A_T . For the treated samples, the observed decrease in pH is solely attributable to decreasing A_T through time. The initial offset
 198 in pH_T , whereby pH_T (untreated) was greater than pH_T (treated), was expected based on the substantial initial alkalinity
 199 difference between the treated and untreated samples.

200 Nutrient results collected from each Niskin before and after borosilicate glass bottle sampling are consistent with the conclusion
 201 that the waters sampled by the two Niskin bottles were somewhat different (Table 1). For inorganic nitrogen, phosphate, and
 202 ammonia, the nutrient concentrations in Niskin 1 were 1.4 to 2.5 times greater in than in Niskin 2, while silica in Niskin 2 was
 203 1.3 times greater than in Niskin 1. Although this is substantial evidence for real distinctions between the initial conditions of
 204 the treated and untreated samples (rather than differences created during laboratory analyses), it is the large changes in DIC_T ,

205 A_T , and pH_T through time, and the increasingly large differences between treated and untreated samples that is the critically
 206 important focus of this investigation (i.e., Fig. 2, 3 and 4).

207 **Table 1. Mean and standard deviation of measured inorganic nutrients sampled from each Niskin bottle at the time of sample**
 208 **collection.**

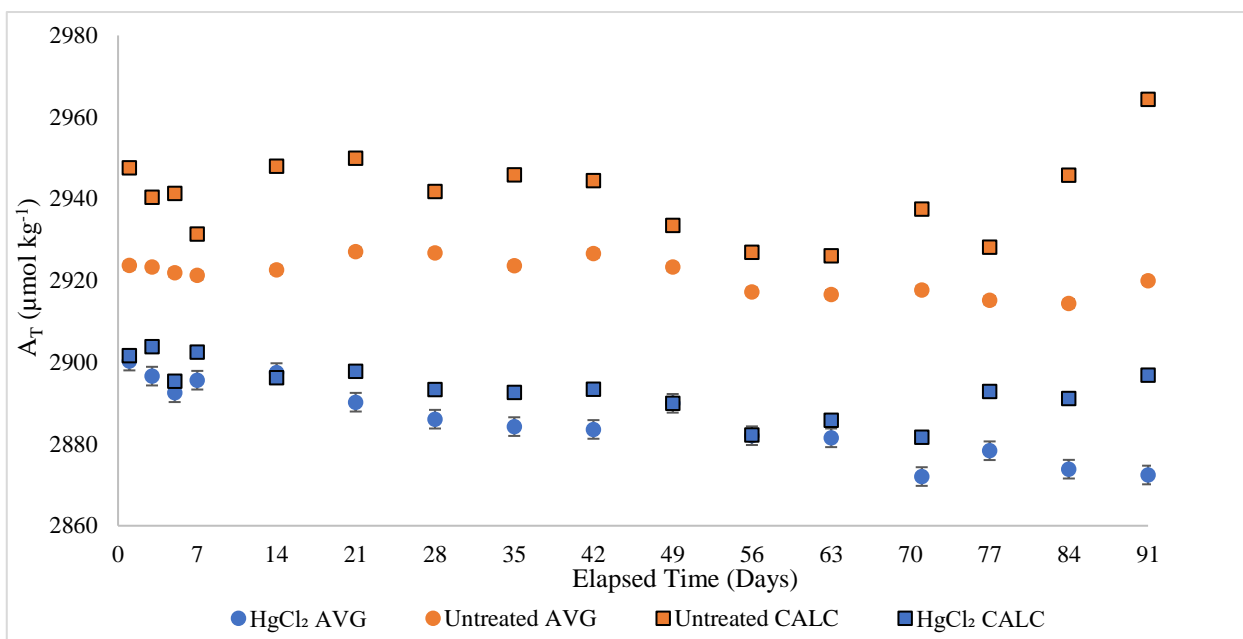

Inorganic Nutrient AVG ($\mu\text{mol kg}^{-1}$)	Niskin 1 (HgCl_2 -treated)	Niskin 2 (Untreated)
Nitrogen	4.90 ± 0.16	1.93 ± 0.35
Ammonia	4.19 ± 0.21	2.99 ± 0.5
Phosphate	2.31 ± 0.02	1.32 ± 0.10
Silica	70.03 ± 0.39	90.23 ± 0.42

209
 210 Contrary to our original expectations, the treated A_T samples (Fig. 3) showed a larger decrease in A_T than the untreated samples.
 211 Our interpretation that this decrease was due to complexation of DOM by Hg^{II} is in accord with the results and interpretation
 212 of Mos et al. (2021). Hg^{II} has a strong affinity for organic ligands such as are found in the DOM of natural waters (Andren and
 213 Harriss, 1975; Mierle and Ingram, 1991; Varshal et al., 1996; Ravichandran, 2004). The increasing A_T difference between
 214 treated and untreated samples over time is plausibly attributable to a slowly increasing extent of DOM complexation by Hg^{II} .
 215 After the addition of a comparable concentration (0.03%) of HgCl_2 to fresh, estuarine, and groundwater water samples stored
 216 in borosilicate glass bottles, Mos et al. (2021) observed a rapid decrease in A_T followed by a subsequent decrease over a period
 217 of 1 or 6 months. A decrease in the alkalinity of treated DOM rich samples would be expected if organic bases are complexed
 218 by Hg^{II} and a portion of these complexes do not dissociate (i.e., remain untitrated) at the lowest pH in an alkalinity titration.
 219 The Hillsborough River headwaters originate in the Green Swamp and Crystal Springs, (Lewis and Estevez, 1988) whose
 220 water types are known to be significant sources of dissolved organic groups with substantial and wide ranging affinities for H^+
 221 ions (Song et al., 2020). As such, these organics are expected to have substantial affinities for cations such as Hg^{II} that exhibit
 222 strong covalent behavior (Martell and Hancock, 2013). Such associations are much weaker in seawater because of strong
 223 complexation of Hg^{II} by chloride ions at high salinities.

224 The initial pH_T and A_T differences (treated vs untreated) in the first weeks of the measurements were initially unexpected.
 225 However, as shown in Table 1, initial differences in A_T , pH_T , and DIC_T for the treated and untreated water samples were
 226 consistent with well defined differences in observed inorganic nutrient concentrations. The most plausible explanation for the
 227 initial DIC_T differences in the treated and untreated water samples is that the two water samples had small differences in their
 228 characteristics. The most plausible explanation for the large initial A_T and pH_T differences between treated and untreated
 229 samples is initial differences between the collected water samples and is consistent with the observations by Mos et al. (2021)
 230 of rapid complexation of organic bases by Hg^{II} that decreased A_T and released H^+ ions. The extent of this complexation then
 231 continued over a period of months (Fig. 3).

232 Calculated values of A_T were larger than measured values for both the untreated and treated samples (Fig. 5). For untreated
 233 samples the average difference between measured and calculated A_T ($A_T(\text{measured}) - A_T(\text{calculated})$) was $-19.5 \pm 9.2 \mu\text{mol kg}^{-1}$
 234 1 and the average difference for the treated samples was $-7.52 \pm 6.8 \mu\text{mol kg}^{-1}$.

235 **Figure 5. Average (AVG) measured versus calculated (CALC) A_T for untreated and treated (HgCl_2) samples over elapsed time.**
 236 **Error bars are the standard deviation of the average from each day of analysis. Calculated A_T measurements were performed with**
 237 **$\text{CO}_2\text{sys.m}$ using measured pH_T and DIC_T for the respective sample type.**
 238

239 In the context of internal consistency measurements for open ocean conditions (high salinity, low DOM), Fig. 5 observations
 240 for treated samples ($A_T(\text{measured}) - A_T(\text{calculated}) = -7.52 \pm 6.8 \mu\text{mol kg}^{-1}$) are comparable to similar calculations (Patsavas
 241 et al., 2015) made in open ocean waters. In contrast, the difference between measured and calculated A_T for untreated samples
 242 was greater. The reason for the substantial difference in the magnitudes of $A_T(\text{measured})$ minus $A_T(\text{calculated})$ between treated
 243 and untreated samples is unclear. Furthermore, while the results shown in Fig. 3 imply that the contributions of organic
 244 alkalinity to A_T were substantial, the observation that $A_T(\text{calculated}) > A_T(\text{measured})$ for both treated and untreated samples
 245 is inconsistent with the fact that $\text{CO}_2\text{sys.m}$ calculations do not (i.e., cannot) account for organic alkalinity contributions to A_T .
 246 The observation that measured A_T is not larger than calculated A_T (Fig. 5) points to potential problems with algorithms for
 247 CO_2 -system calculations at low salinities. Resolution of this issue (i.e., differences in measured and calculated A_T) will require
 248 further detailed investigation of CO_2 -system characteristics in organic-rich estuarine waters.

249 4. Improved approach for sample preservation in organic rich waters

250 The overarching objective of sound storage and preservation methods is to maintain samples so that they reflect the *in situ*
 251 carbonate system characteristics of the samples at the time of collection. The results demonstrate that for DIC_T measurements,

252 poisoning samples with HgCl_2 is effective in achieving this objective (Fig. 2). Over a period of three months, DIC_T
253 measurements for the treated samples were essentially invariant while the filtered samples that were not treated exhibit
254 substantial changes. Although it is possible that sample storage at low temperatures, as advocated by Mos et al. (2021), would
255 reduce or even eliminate the respiration derived generation of DIC_T shown in untreated samples, the effectiveness of HgCl_2
256 additions is unequivocal. A key point here is that, while Mos et al. (2021) demonstrated that their procedures effectively
257 eliminated changes in A_T , it is much easier to detect changes in DIC_T than for A_T (i.e., $\Delta\text{DIC}_T/\Delta A_T = 7.3$). Unless further work
258 demonstrates that filtration in conjunction with low temperature storage eliminates changes in DIC_T , it appears prudent to
259 preserve samples intended for analysis of DIC_T with HgCl_2 additions.

260 With respect to preservation of organic-rich samples for A_T analysis, addition of HgCl_2 and subsequent long-term storage is
261 ineffective (Fig. 3). Interactions of DOM and Hg^{II} in organic-rich samples appear to increase through time, and this confounds
262 interpretation of A_T results obtained using treated samples. In contrast, for untreated samples, although decreases in A_T are
263 observed that are broadly consistent with the increases in DIC_T (Fig. 2) the changes are small. As such, as shown in the study
264 of Mos et al. (2021), it is possible that storage at lower temperature would further reduce changes in A_T during storage.
265 Therefore, consistent with the results of Mos et al. (2021), improved accuracy of measurements for A_T analysis can be achieved
266 when samples are filtered, stored in polypropylene bottles, and refrigerated at 4°C . Minimizing the time between sample
267 collection and analysis improves accuracy of results (Fig. 3). Notably, preserving DIC_T samples with HgCl_2 , but not A_T
268 samples, requires that the two types of samples are stored separately.

269 The results shown in Fig. 4 indicate that long-term storage of samples for pH_T analyses affects accuracy of results. Sample
270 pH_T is sensitive to changes in DIC_T and A_T . In the absence of Hg^{II} additions, respiration increases DIC_T (Fig. 2) thereby
271 decreasing the pH_T . For treated samples, changes in A_T can create problems with pH_T measurements. The solution to this issue
272 is prompt pH_T measurements at the time of collection. In contrast to measurements of DIC_T and A_T , spectrophotometric pH_T
273 measurements are uniquely amenable to analysis in the field. As an alternative, if measurements of pH_T in the laboratory are
274 preferred, measurements of pH_T over one week of storage (Fig. 4) were similar to field pH_T measurements obtained
275 immediately before the samples were bottled.

276 Although further investigation of sample preservation and storage could be beneficial, the results obtained in this study support
277 the following improvements for CO_2 system sample collection and analysis of organic-rich waters:

- 278 • Accurate analyses of DIC_T can be achieved by filtration and preservation with HgCl_2 .
- 279 • A_T analyses can be improved by filtration and storage in polypropylene bottles at 4°C (Mos et al., 2021). Preservation
280 with HgCl_2 is not advisable.
- 281 • Good quality measurements of pH_T can be obtained by prompt analyses in the field. If this is not feasible, then samples
282 can be preserved with HgCl_2 and measured in the laboratory within approximately one week.

283 *Data availability.* The data related to this article is available online at <https://doi.org/10.5066/P9J9IYFD>, 2022 (Moore et al.,
284 2022). A provisional data release link prior to publication for is available at [https://coastal.er.usgs.gov/data-
285 release/provisional/ip139775/](https://coastal.er.usgs.gov/data-release/provisional/ip139775/).

286 *Author contributions.* CM and RB designed the experiments and CM carried them out. CM and RB prepared the manuscript
287 with contributions from KY. RB and KY reviewed and edited the manuscript.

288 *Competing interests.* The contact author has declared that neither they nor their co-authors have any competing interests.

289 *Acknowledgments.* We thank Andrew Warren and Robert Walker at the Florida Institute of Oceanography (FIO) for providing
290 the Niskin bottles used in this work. We also thank Rob Masserini for providing nutrient analyses. Any use of trade, firm, or
291 product names is for descriptive purposes only and does not imply endorsement by the U.S. Government.
