22

23 **Text S1.** Sampling of aerosol filters.

24 We collected ambient aerosols at Cape D’Aguilar Super Site in Autumn for
25 photochemical aging experiments. The PM_{2.5} samples were collected on quartz-fiber
26 filters (8 × 10 inches) using a PUF-1000 high-volume sampler with a flow rate of 999
27 Lpm in 2020. All samplings were performed from 11:00 am local time (LT) to 10:00
28 am LT of the next day. The filters were pre-fired at 900 °C for 4 hours to remove organic
29 artifacts and stored in a freezer at -20 °C. Fractions with a given surface area from one
30 randomized-chosen filter were used to perform the photochemical experiments or other
31 analyses.

32

33 **Text S2.** Additional setting information on the box model simulation of 28 September
34 2021.

35 The observation data on 28 September was used as input to constrain the model with
36 a time step of 5 min (Table S3). The data of trace gases (including O₃, NO, NO₂, CO
37 and SO₂) and data obtained by ToF-CIMS (including HONO and N₂O₅) were averaged
38 to 5-min resolution. For the VOCs and OVOCs species, linear interpolations were
39 applied. The variables “ModelOptions.EndPointsOnly” and “ModelOptions.LinkSteps”
40 were set to “1”. The variable “ModelOptions.IntTime” was set to “300”. No family
41 conservation was used. Readers are referred to a F0AM description paper for more
42 information (Wolfe et al., 2016).

43

44 **Text S3.** The determination of $J_{\text{NO}_3(\text{aq})}$ and $J_{\text{O}_3 \rightarrow \text{O}^1\text{D}}$ in the chamber and ambient air.

45 The $J_{\text{NO}_3(\text{aq})}$ and $J_{\text{O}_3 \rightarrow \text{O}^1\text{D}}$ in the chamber was calculated by (Eq. (1)),

46
$$J = \int q(\lambda)\sigma(\lambda)I(\lambda)d\lambda \quad (1)$$

47 where $q(\lambda)$ is the quantum yield at wavelength λ (nm); $\sigma(\lambda)$ is the cross-section at
48 wavelength λ ; $I(\lambda)$ is the flux of xenon lamp at wavelength λ and was calculated by
49 converting the irradiation energy spectra of the lamp (Fig. 6d) to photon flux based on
50 Planck's equation. The $q(\lambda)$ and $\sigma(\lambda)$ of aqueous nitrate at 298 K were derived from
51 (Chu & Anastasio, 2003). The $q(\lambda)$ and $\sigma(\lambda)$ of O₃ generating O¹D were adopted from
52 the recommended value from IUPAC under 298 K (<https://uv-vis-spectral-atlas-mainz.org/uvvis/index.html>). The $J_{\text{NO}_3(\text{aq})}$ and $J_{\text{O}_3 \rightarrow \text{O}^1\text{D}}$ in the ambient was calculated
53 by the Tropospheric Ultraviolet and Visible (TUV) radiation model
54 (https://www.acom.ucar.edu/Models/TUV/Interactive_TUV/) under clear sky
55 conditions and then scaled to the field-measured $j\text{NO}_2$.

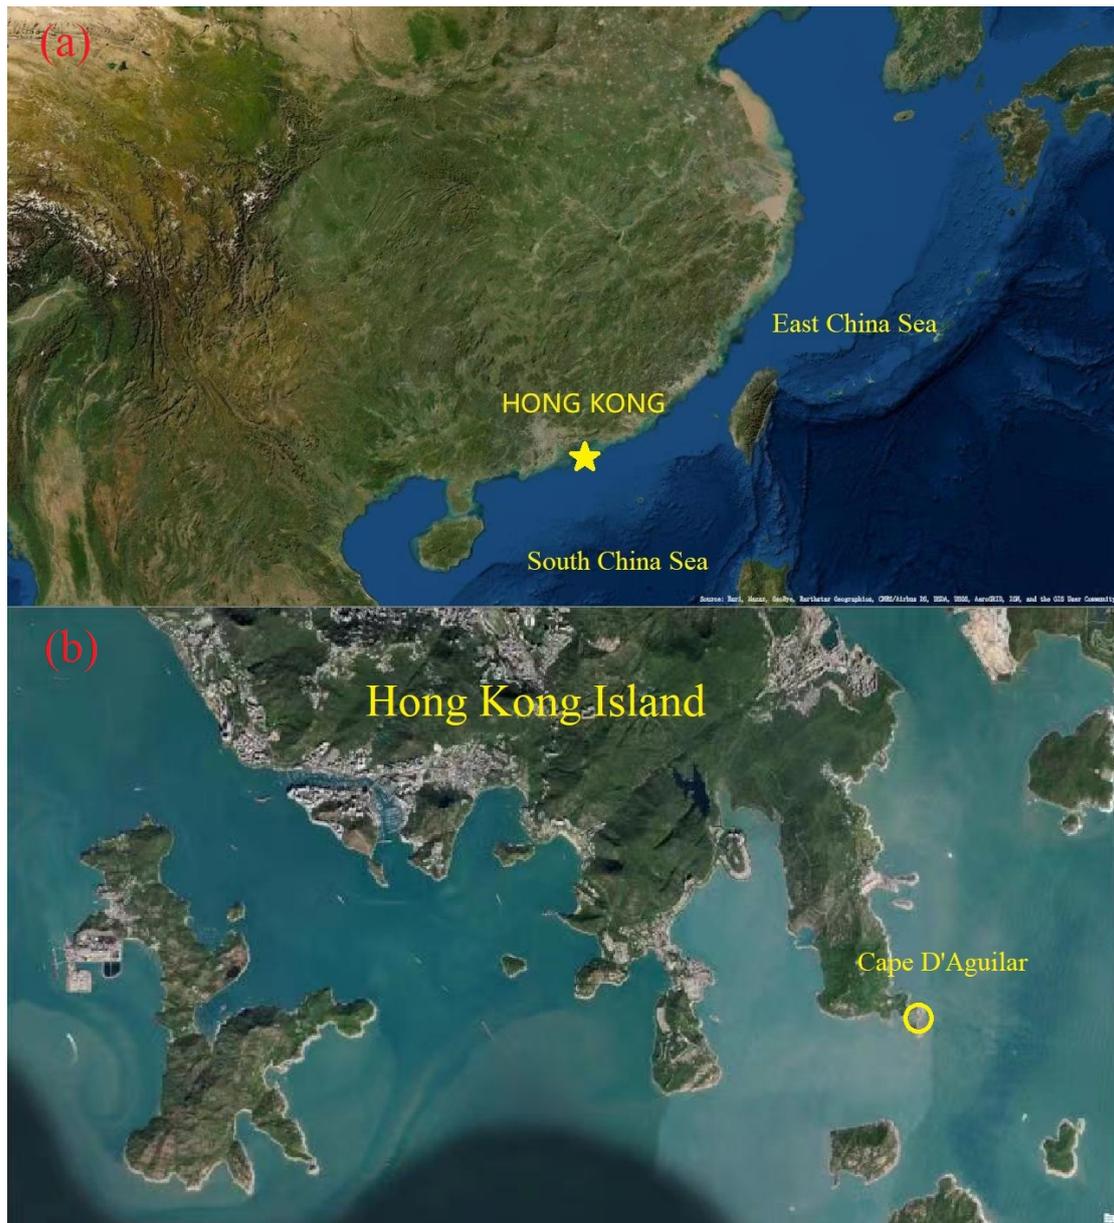

56

57 **Text S4.** Additional laboratory experiments.

58 Since HONO and HCOOH were simultaneously observed during the photochemical
59 aging process, it is possible that HCOOH was produced from the heterogeneous
60

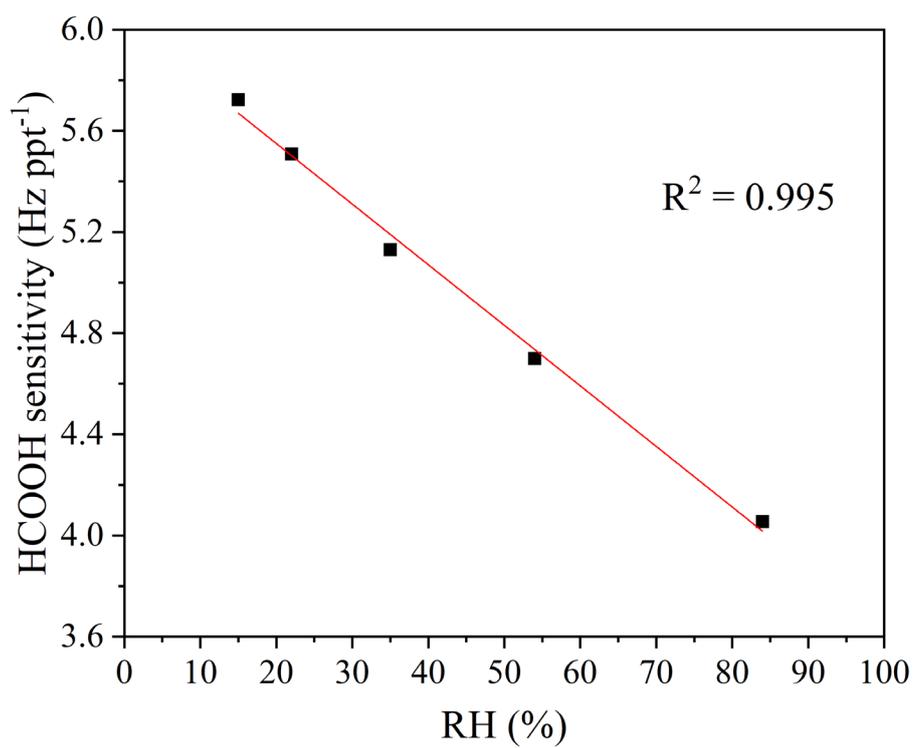

61 reactions between gas-phase OH radicals and particles. To check this possibility, an
62 experiment was conducted as follows (Fig. S7). 4 Lpm HONO-containing air (78% RH,
63 7.2 ppb HONO, balanced with zero air) was injected into the chamber. The solution
64 was prepared with 0.15 wt.% HCHO but without adding NaNO₃. The pH of the solution
65 was also adjusted to 2.7 using sulfuric acid. The background HCOOH concentration
66 was determined as 308.9 ppt when illuminating the chamber without the solution. After
67 adding the solution, the HCOOH concentration increased to 428.8 ppt. After
68 normalizing the HONO concentration in this experiment to that in the previous solution
69 experiments containing NaNO₃ (0.77 ppb HONO, 0.62 ppb HCOOH) (Fig. 6c), the
70 increased HCOOH concentration is 12.8 ppt, which is negligible. The conclusion is the
71 same when compared with the filter irradiation experiments (4.1 ppb HONO, 5.6 ppb
72 HCOOH). Therefore, the HONO photolysis contributes little to HCOOH production.
