12 **S1 In situ measurements and data**

13 Concentrations of NO/NO<sub>x</sub>(=NO+NO<sub>2</sub>), CO, O<sub>3</sub> and SO<sub>2</sub> were obtained from the Hungarian Air Quality  
14 Network (Salma et al., 2020a). They were determined by chemiluminescence (Thermo 42C), IR  
15 absorption (Thermo 48i), UV absorption (Ysselbach 49C) and UV fluorescence (Ysselbach 43C)  
16 methods, respectively with a time resolution of 1 h. In the rural background and suburban area, the  
17 concentrations were obtained directly at the sampling locations. In the city centre, the pollutants were  
18 measured in 4.5 km in the upwind prevailing direction from the sampling site.

19  
20 In the city centre, particle number size distributions were also determined by a flow-switching-type  
21 differential mobility size spectrometer in a diameter range from 6 to 1000 nm in 30 channels in the dry  
22 state of particles with a time resolution of 8 min (Salma et al., 2016). Concentrations in several size  
23 fractions were calculated. Of them, the daily mean concentrations of the total particles ( $N_{6-1000}$ ) and of  
24 particles in the diameter range of 25–100 nm ( $N_{25-100}$ ) were used here. The latter concentration is often  
25 associated with emission sources from vehicles (Salma et al., 2020b).

26  
27 Local air temperature ( $T$ ) and relative humidity (RH) data were acquired by standardised meteorological  
28 methods (anemometer HD52.3D17, Delta OHM, Italy or Vaisala HMP45D and Vaisala WAV15A,  
29 Finland) on sites with a time resolution of 1 min (Salma et al., 2022).

30

31 **Table S1.** Ranges and averages of the daily concentrations for NO, NO<sub>2</sub>, CO, O<sub>3</sub> and SO<sub>2</sub> (all in µg m<sup>-3</sup>), for total particle  
 32 numbers ( $N_{6-1000}$ ) and particles in the diameter range of 25–100 nm ( $N_{25-100}$ , both in  $\times 10^3$  cm<sup>-3</sup>) and of air temperature ( $T$ , °C)  
 33 and relative humidity (RH, %) in the rural background, suburban area and city centre. The average is median for the  
 34 concentrations and mean for the meteorological data.

35

Site/ Variable	Rural background			Suburban area			City centre

## 36 S2 Details of aerosol source interpretation

37 The interpretation of the factors derived by the PMF modelling was based on the presence and amounts  
 38 of their marker chemical species, on the tendencies in the time series of the factor intensities, on the crustal  
 39 enrichment factors (Table S2; e.g. Salma and Maenhaut, 2006), and on the correlations with selected  
 40 variables and the other sources (Table S3).

41

42 The BB source was identified by high shares of LVG, K, EC, OC and Rb (Fig. S1). It also contained Cl,  
 43 Br, Zn and Pb, which could originate from agricultural-waste and household-waste burnings, including  
 44 (illegal) burnings of some solid materials such as plastics, furniture, fibreboards, tyres and coloured paper  
 45 together with biomass (Hoffer et al., 2021). Its intensity was the largest in winter, substantial in autumn  
 46 and very low in spring and summer. The intensity of the BB source resulted in the largest significant and  
 47 positive coefficient of correlations (0.97–0.99) with EC<sub>BB</sub> and OC<sub>BB</sub> at all sites and they were also large  
 48 and significant with PM<sub>2.5</sub> mass. Its correlations with O<sub>3</sub> were significant and negative due to the seasonal  
 49 tendencies of BB and O<sub>3</sub> and to additional common factors governing them.

50

51 The suspended dust source showed the largest contributions from crustal elements such as Ti, Ca, and Fe  
 52 (Fig. S2). At the rural location, it was virtually fugitive mineral and soil dust made of geogenic elements.  
 53 In the urban sites, the dust also comprised further constituents including S (mainly anthropogenic  
 54 according to its crustal EF in Table S2), V (partly anthropogenic), EC, OC, Ba (partly anthropogenic) and  
 55 Br (mainly anthropogenic). The effect of the Saharan dust intrusion into the Carpathian Basin on 15 April

2018 showed up evidently and with extremely high source intensities at each location. The intensity of the dust source in the rural background was considerable in spring and summer (dryer or arid time periods), and low in winter and autumn. The agricultural activity contributed to the seasonal character as well. The intensity of the suspended dust source in the urban sites was less dependent on season. This can be explained by the increasing importance of traffic-blown dust to wind-blown dust. At these locations, construction activities can also produce fugitive dust enriched in Ca and Mg. Suspended dust anticorrelated significantly with the BB in the rural background and suburban area due to their seasonal tendencies (e.g. land surface areas are often wet or covered with snow in winter and autumn when BB is intensive).

65

**Table S2.** Mean crustal enrichment factors for the apportioned elemental concentrations in the suspended dust source for PM<sub>2.5</sub> size fraction relative to the average upper continental crustal rock composition with Ti as the lithogenic reference element separately in the rural background, suburban area and city centre.

69

Site/ Element	Rural background	Suburban area	City centre
S	–	1729	1388
Ca	2.5	3.7	4.4
V	–	4.3	3.8
Mn	–	2.8	2.9
Fe	1.0	1.9	2.1
Br	–	456	471
Ba	–	4.6	5.0
Pb	–	–	251

70

The road traffic source exhibited large contributions of EC, OC, Zn, Br, Mn, Cl, V, Ca, Ba, Pb, Cu and Fe (Fig. S3). Its intensity was basically balanced over the year. It also showed monotonic increase in the intensity from the rural background through the suburban area to the city centre. It exhibited strong and significant correlations with NO, NO<sub>x</sub> and CO at the urban sites. Its coefficients of correlation with  $N_{6-1000}$  (0.74),  $N_{25-100}$  (0.81) and metal wear factor (0.77) were significant in the city centre.

76

The oil combustion source comprised large contributions of V, S, Mn, OC, Ni and Rb (Fig. S4). Its intensity was fairly constant over the whole year. It significantly correlated with the dust source in the rural background and suburban area ( $R=0.55$  and  $0.32$ , respectively) and with the SOC (0.68) in the city centre. It cannot be fully excluded that the oil combustion was partly mixed with coal combustion due to their collinearity caused by meteorological conditions in winter (Sect. 3.5).

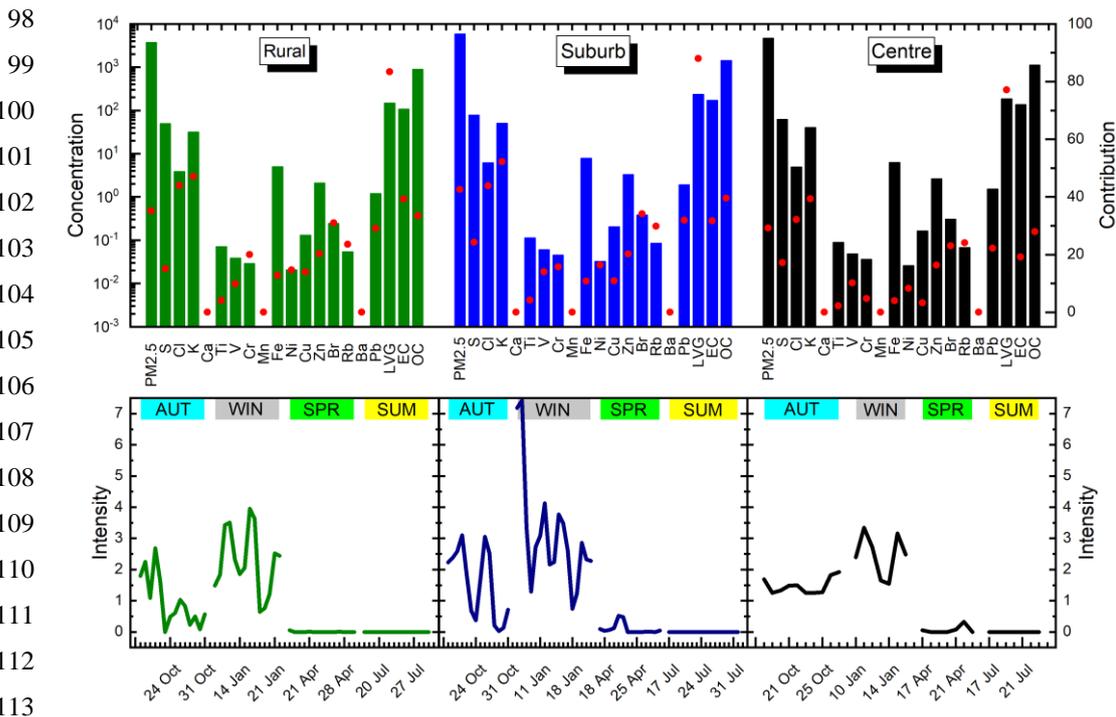

82

83 The metal wear of vehicles was related to primary aerosol particles containing large contributions of Cr,  
 84 Cu, Fe, Ni, Ba, Mn and Pb (Fig. S5). Its source intensity was balanced over the year at each location and  
 85 followed that of road vehicle traffic. It showed no significant correlation in the rural background, while  
 86 it correlated significantly and positively with vehicle traffic ( $R=0.77$ ) and mixed industrial source (0.67)  
 87 in the city centre. In the urban locations, it also exhibited significant positive correlations with  $SO_2$ ,  $NO$ ,  
 88  $CO$ ,  $N_{6-1000}$  and  $N_{25-100}$ . They all suggested that this source could be another statistical realisation or  
 89 consequence of road traffic.

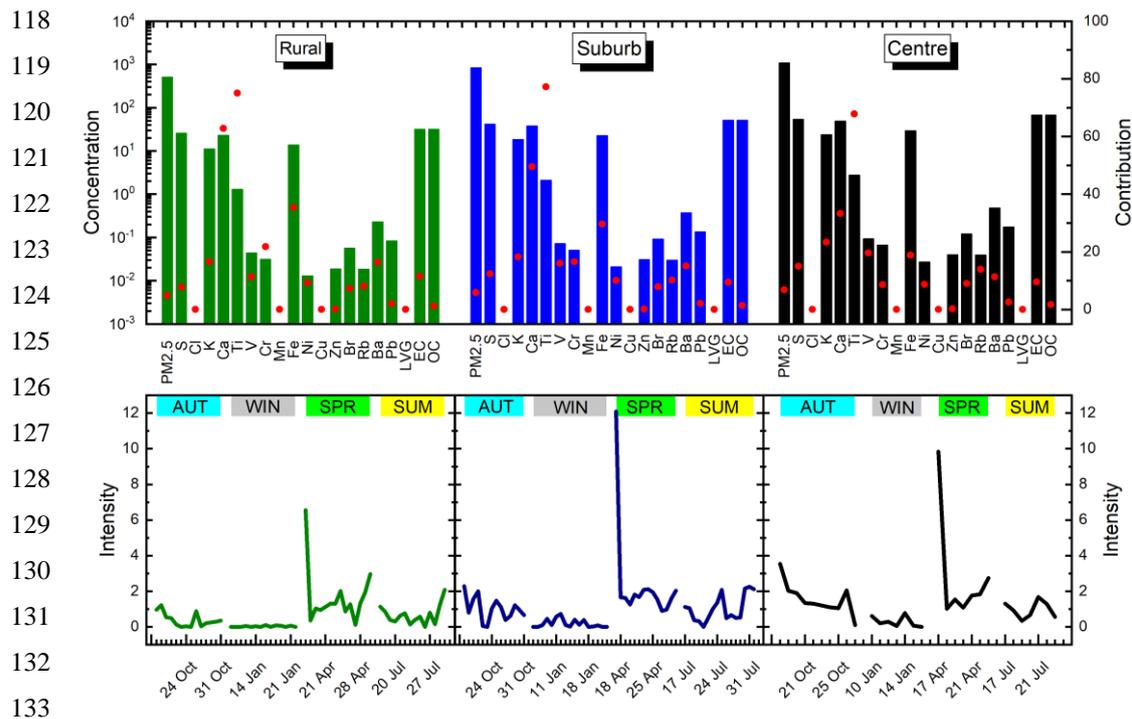

90

91 The last factor contained large contributions from Zn and also involved considerable shares of Ni, Pb, Cl  
 92 and Ba (Fig. S6). Its source intensity was fairly balanced over the year at each location. At the urban sites,  
 93 it correlated significantly and positively with  $SO_2$ ,  $OC_{FF}$  and  $EC_{FF}$ . It cannot be completely excluded that  
 94 its separate appearance was fostered by a few samples containing high concentrations of Zn. At the same  
 95 time, it showed no significant correlation in the rural background. Therefore, it was interpreted as a mixed  
 96 industrial source.

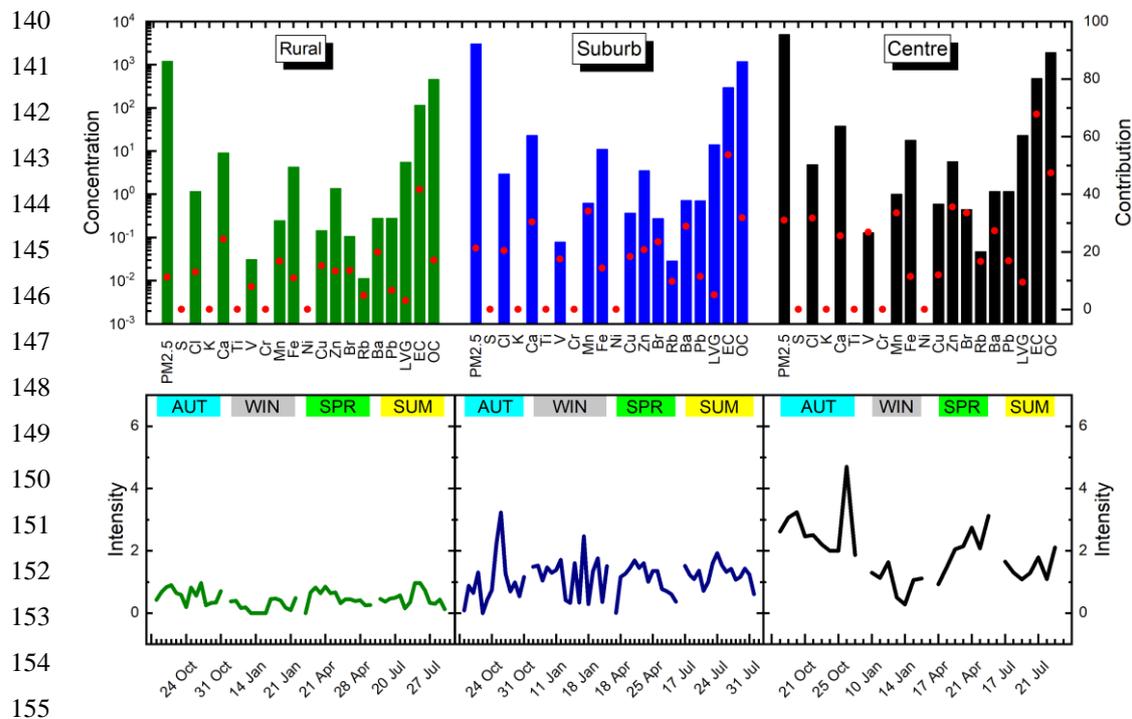

97

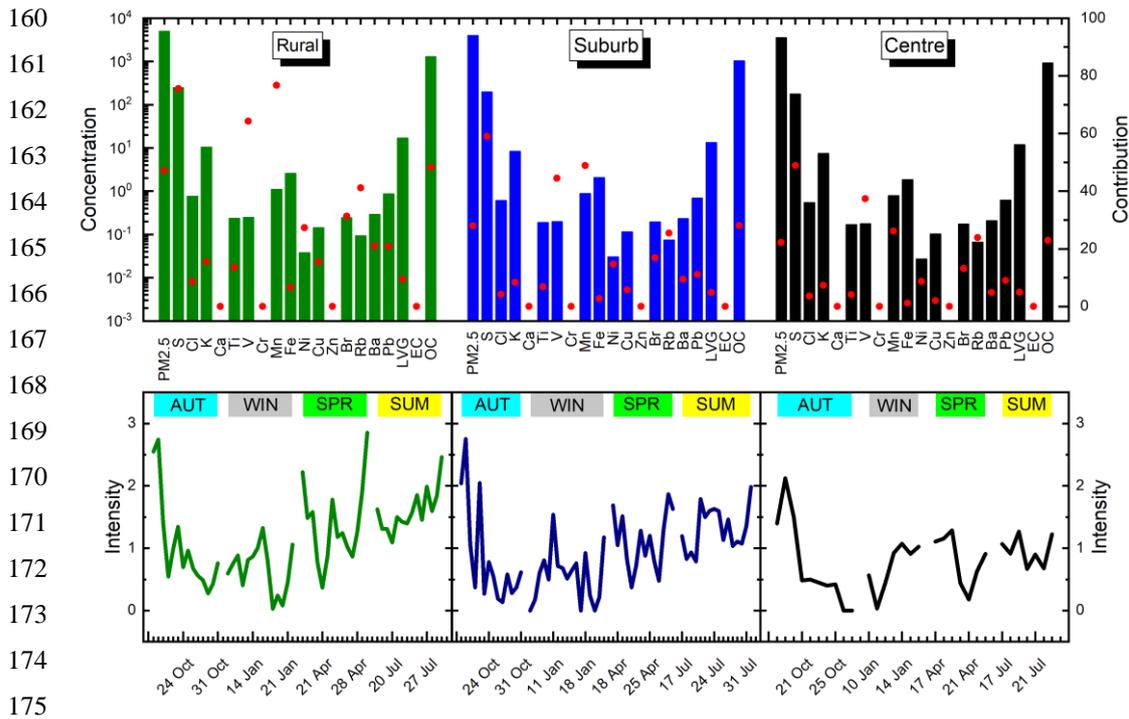

114 **Figure S1.** Concentrations of aerosol constituents (factor profiles, in  $ng\ m^{-3}$ ; top panels, column bars) assigned to biomass  
 115 burning source, mean contributions of this factor to total concentrations (in %; top panels, red dots) and time series of the  
 116 factor intensity (bottom panels) separately for rural background, suburban area and city centre. The seasons are indicated on  
 117 the bottom panels.

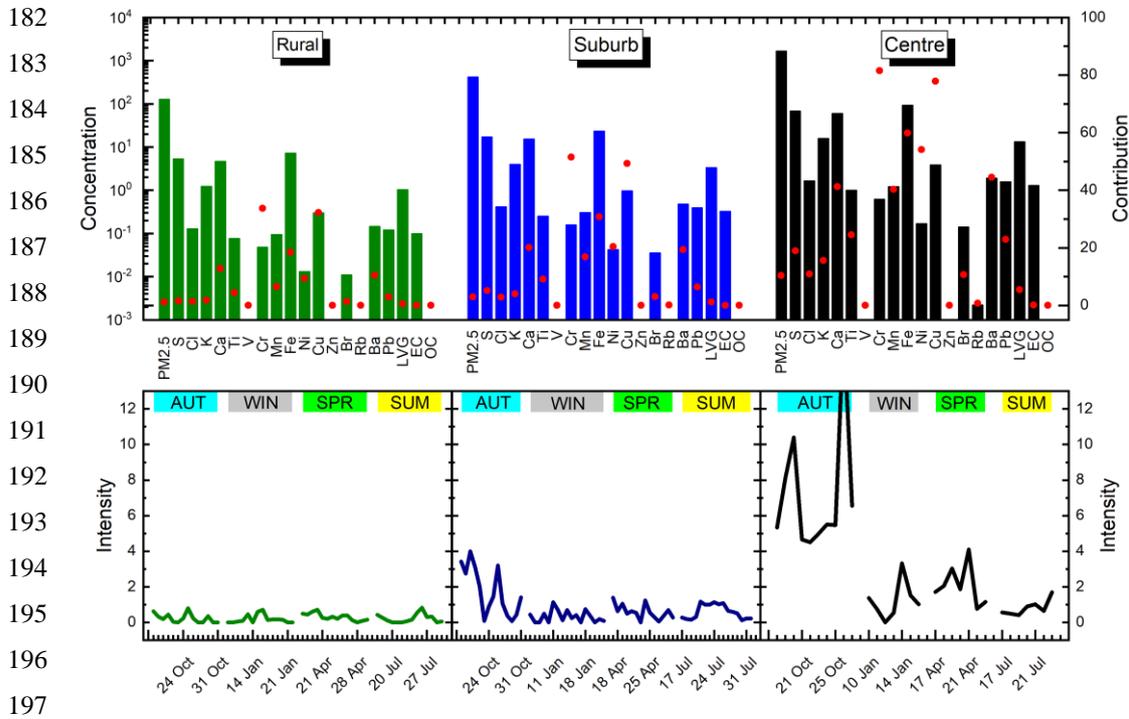

134 **Figure S2.** Concentrations of aerosol constituents (factor profiles, in  $\text{ng m}^{-3}$ ; top panels, column bars) assigned to suspended  
 135 dust source, mean contributions of this factor to total concentrations (in %; top panels, red dots) and time series of the factor  
 136 intensity (bottom panels) separately for rural background, suburban area and city centre. The seasons are indicated on the  
 137 bottom panels.

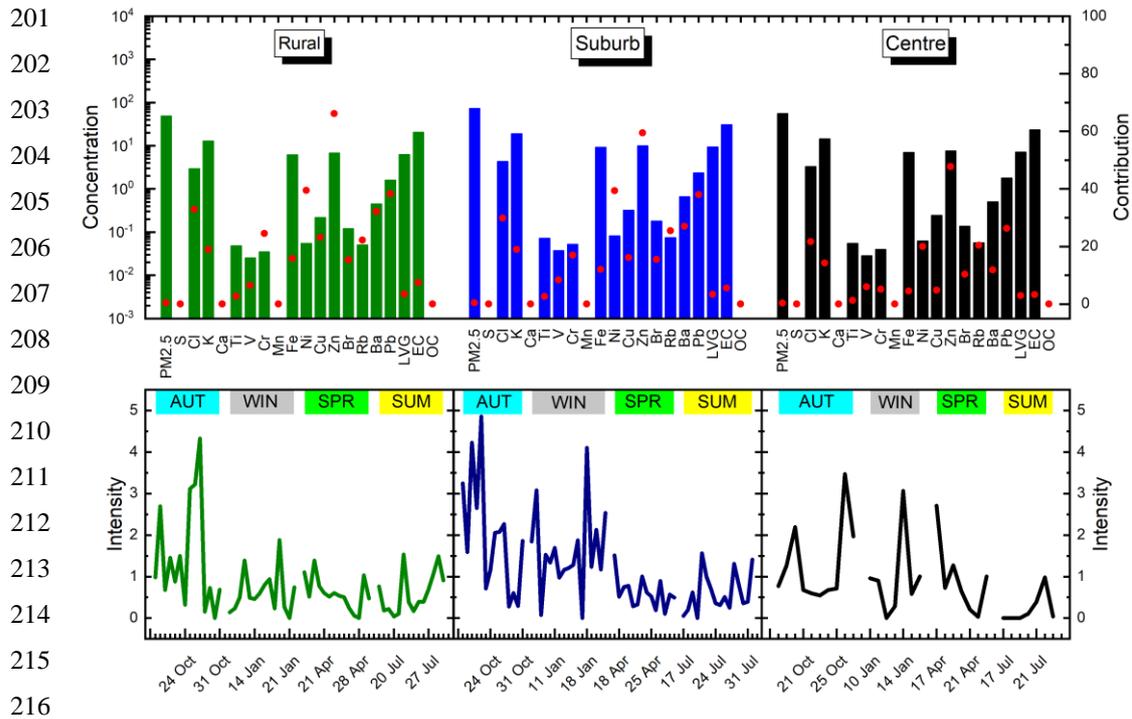

156 **Figure S3.** Concentrations of aerosol constituents (factor profiles, in  $\text{ng m}^{-3}$ ; top panels, column bars) assigned to road traffic  
 157 source, mean contributions of this factor to total concentrations (in %; top panels, red dots) and time series of the factor  
 158 intensity (bottom panels) separately for city centre, suburban area and rural background. The seasons are indicated on the  
 159 bottom panels.

176 **Figure S4.** Concentrations of aerosol constituents (factor profiles, in  $\text{ng m}^{-3}$ ; top panels, column bars) assigned to residual oil  
 177 combustion source, mean contributions of this factor to total concentrations (in %; top panels, red dots) and time series of the  
 178 factor intensity (bottom panels) separately for rural background, suburban area and city centre. The seasons are indicated on  
 179 the bottom panels.

198 **Figure S5.** Concentrations of aerosol constituents (factor profile, in  $\text{ng m}^{-3}$ ; top panels, column bars) assigned to vehicle metal  
 199 wear, mean contributions of this factor to total concentrations (in %; top panels, red dots) and time series of the factor intensity  
 200 (bottom panels) separately for city centre, suburban area and rural background. The seasons are indicated on the bottom panels.

217 **Figure S6.** Concentrations of aerosol constituents (factor profile, in  $\text{ng m}^{-3}$ ; top panels, column bars) assigned to mixed  
 218 industrial source, mean contributions of this factor to total concentrations (in %; top panels, red dots) and time series of the  
 219 factor intensity (bottom panels) separately for rural background, suburban area and city centre. The seasons are indicated on  
 220 the bottom panels.

238 **Figure S7.** Mean contributions of biomass burning, suspended dust, road traffic, oil combustion, vehicle metal wear, mixed  
 239 industrial source and unaccounted sources to atmospheric concentration of Cu (in %) as derived by PMF modelling in the rural  
 240 background, suburban area and city centre in different seasons. The median atmospheric concentrations are shown under the  
 241 circle charts.

263 **Figure S8.** Mean contributions of biomass burning, suspended dust, road traffic, oil combustion, vehicle metal wear, mixed  
264 industrial source and unaccounted sources to atmospheric concentration of Fe (in %) as derived by PMF modelling in the rural  
265 background, suburban area and city centre in different seasons. The median atmospheric concentrations are shown under the  
266 circle charts.

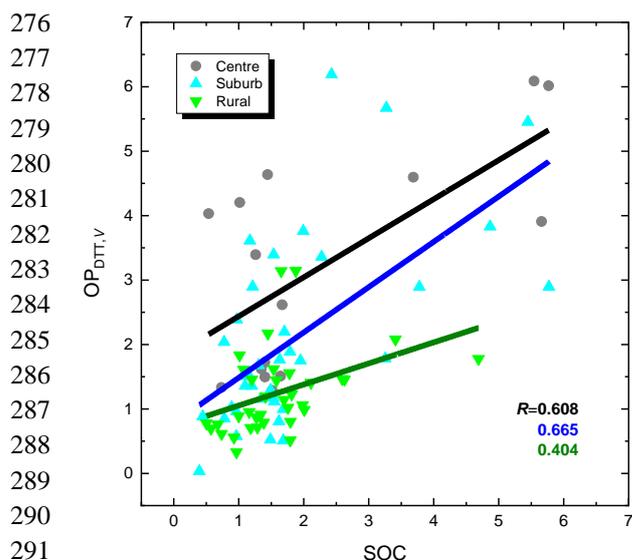

### 267 S3 Correlations of oxidative potential with main aerosol sources and secondary organic carbon

268 **Table S3.** Pearson's coefficients of correlation between the oxidative potential (OP) determined by AA and DTT assays  
269 normalised to PM<sub>2.5</sub> mass ( $m$ ;  $OP_{AA,m}$  and  $OP_{DTT,m}$ , respectively, in  $\text{nmol min}^{-1} \mu\text{g}^{-1}$ ) on the one side and the identified main  
270 aerosol sources of biomass burning, suspended dust, road traffic, oil combustion, vehicle metal wear and mixed industrial  
271 source on the other side in the rural background, suburban area and city centre. The significance of the correlations was  
272 evaluated by Student's t-test at a confidence level of  $p=0.05$ . The total number of samples is denoted by  $n$ . The nonsignificant  
273 correlations are indicated in *Italic font*.

274

Source Site, variable	Biomass burning	Suspended dust	Road traffic	Oil combustion	Metal wear	Industrial source
Rural background ( $n=56$ )						
$OP_{AA,v}$	0.88	<i>-0.21</i>	<i>-0.22</i>	<i>-0.13</i>	<i>0.04</i>	<i>0.08</i>
$OP_{DTT,v}$	0.39	<i>-0.07</i>	<i>-0.06</i>	<i>0.27</i>	<i>-0.16</i>	<i>0.07</i>
Suburban area ( $n=59$ )						
$OP_{AA,v}$	0.94	<i>-0.30</i>	0.27	<i>-0.31</i>	<i>0.12</i>	0.53
$OP_{DTT,v}$	0.60	<i>-0.17</i>	<i>-0.15</i>	<i>0.21</i>	0.37	0.55
City centre ( $n=28$ )						
$OP_{AA,v}$	0.85	<i>-0.14</i>	0.30	<i>-0.30</i>	0.55	<i>0.42</i>
$OP_{DTT,v}$	0.63	<i>-0.03</i>	0.47	<i>-0.12</i>	0.64	<i>0.42</i>

275

292 **Figure S9.** Scatter plots of oxidative potential (OP) determined by DTT assay and normalised to sampled air volume ( $V$ ;  
 293  $OP_{DTT,V}$ , in unit of  $\text{nmol min}^{-1} \text{m}^{-3}$ ) and secondary organic carbon (SOC,  $\mu\text{g m}^{-3}$ ) for the rural background, suburban area and  
 294 city centre. The lines represent linear regressions of the corresponding data points. The coefficients of correlation ( $R$ s) are also  
 295 indicated. The slopes and SDs of the regression lines are  $0.33 \pm 0.12$ ,  $0.70 \pm 0.16$  and  $0.61 \pm 0.19 \text{ nmol min}^{-1} \mu\text{g}^{-1}$ , respectively.

#### 296 S4 Results of multiple linear regression with the weighted least squares approach

297 **Table S4.** Slopes and intercepts of the multiple linear regression with weighted least squares approach between oxidative  
 298 potential (OP) determined by AA and DTT assays and normalised to sampled air volume ( $OP_{AA,V}$  and  $OP_{DTT,V}$ , respectively)  
 299 and the main aerosol sources of biomass burning, suspended dust, road traffic, oil combustion, vehicle metal wear and mixed  
 300 industrial source in the rural background, suburban area and city centre. The number of samples available ( $n$ ) and the  
 301 coefficients of determination ( $R^2$ ) are also shown.  
 302
