22 **Abstract**

23 In the autumn of 2019, ~~A-a~~ five-days long-lasting dust event was observed ~~with~~
24 using a synergy of field measurements techniques in Shanghai ~~in the autumn of 2019~~.

25 ~~This particular dust event stood out from others due to its unique characteristics,~~
 26 ~~Different from most dust events, this dust was an unusual one characterized of including~~
 27 low wind speed, high relative humidity, ~~elevated levels~~ high concentrations of gaseous
 28 precursors, and contrasting wind ~~patterns at different altitudes~~ vectors between low and
 29 high altitudes. ~~During this event, three distinct dust stages were identified. Three dust~~
 30 ~~stages were identified and~~ The first stage was a ~~typical normal~~ dust invasion
 31 characterized by with high concentrations of particulate ~~matters~~ concentrations and but
 32 relatively short duration. In contrast, the second stage exhibited an unusual
 33 enhancement of ozone ~~was observed in the second stage,~~ attributed due to compound
 34 causes of weak synoptic system, transport from the ocean, and subsidence of high-
 35 altitude ozone O_3 down drafted by dust, ~~Consequently~~ As a result, gas phase oxidation
 36 served as the major formation pathway of sulfate and nitrate ~~moderately correlated with~~
 37 ~~O_3 while had almost no correlation with aerosol liquid water content, indicating the~~
 38 ~~dominant role of gas phase oxidations. During~~ In the third stage of dust, a noteworthy
 39 phenomenon known as dust backflow occurred. ~~a special phenomenon of dust backflow~~
 40 ~~was observed that~~ The dust plume ~~originated drifted~~ from the Shandong Peninsula and
 41 ~~slowly drifted~~ travelled slowly over the Yellow Sea and the East China Sea, before
 42 eventually, finally returning to Shanghai. Evidence of this ~~The dust~~ backflow was found
 43 ~~through~~ evidenced by the enrichment of marine vessel emissions (V and Ni) and
 44 increased solubility of calcium. Under the influence of humid oceanic breezes, the
 45 formation of nitrate was dominated by aqueous processing. Additionally, part of nitrate
 46 and sulfate were ~~, while the strong correlation between SO_4^{2-} and Na^+ suggested that a~~
 47 ~~considerable part of sulfate was aged and~~ directly transported via sea salts, evidenced
 48 by ~~their~~ co-variation with Na^+ and confirmed through ~~Based on the~~ thermodynamic

49 modeling, ~~sea salts probably involved more in the secondary aerosol formation than the~~
50 ~~dust heterogeneous reactions.~~ The uptake of NH₃ on particles, influenced by the
51 contributions of alkali metal ions and aerosol pH, regulated the formation potential of
52 secondary aerosol. By developing an upstream-receptor relationship method, the
53 amounts of transported and secondarily formed aerosol species were separated. This
54 study highlights that the transport pathway of dust, ~~coupled with~~ and environmental
55 conditions, ~~could~~ can significantly modify the aerosol properties, especially at the
56 complex land-sea interface.

58 1. Introduction

59 Dust serves as a significant natural source of aerosols, constituting
60 ~~approximately~~ As an important source of natural aerosols, dust accounted for about half
61 of the tropospheric aerosols (Zheng et al., 2016). Dust aerosols played ~~ed~~ crucial important
62 roles in environmental and climatic changes by affecting the radiation balance (Feng et
63 al., 2020; Nagashima et al., 2016; Goodman et al., 2019). The optical properties of dust
64 aerosols are influenced by various parameters of iron oxides, including refractive
65 indices, size distributions, and mineralogical compositions. Consequently, these factors
66 introduce potential uncertainties regarding the role of dust in climate forcing (Zhang et
67 al., 2015; Jeong, 2008). Furthermore, dust aerosols ~~have had~~ important impacts
68 ~~influences~~ on tropospheric chemistry by participating in heterogeneous and photolysis
69 reactions in the atmosphere (Wang et al., 2014; Liu et al., 2018). During transport ~~For~~
70 ~~instance~~, dust ~~could~~ can mix with gaseous pollutants, toxic metals, and soot ~~during~~
71 ~~transport~~, ~~thereby thus~~ affecting air quality immediately and potentially posing ~~causing~~
72 ~~potential~~ public health hazards (Liu et al., 2021; Wang et al., 2021). Moreover, Barkley

73 et al. (2021) found that iron-containing aerosols transported from Africa to the
74 equatorial North Atlantic Ocean provided plentiful nutrients to algae in the ocean and
75 accumulated inside algae.

76 ~~Many studies focused on the emissions and transport of Asian dust, which~~
77 ~~accounted for 20% of the global dust budget (Ginoux et al., 2004). Asian dust mostly~~
78 ~~originated from the deserts in western China, the Gobi, and the Loess Plateau~~
79 ~~(Nagashima et al., 2016). Dust particles can be lifted to an altitude of several kilometers~~
80 ~~due to strong winds and low soil moistures. During this process, most of the coarse dust~~
81 ~~particles would settle near the dust source areas, while relatively fine particles could be~~
82 ~~transported to further downstream regions such as eastern and southern China, and even~~
83 ~~across the Pacific Ocean to the western America coast (Huang et al., 2010b; Vicars and~~
84 ~~Sickman, 2011).~~

85 -The irregular shapes of dust particles provided an efficient medium for
86 heterogeneous reactions with NO₂, O₃, SO₂, and NH₃, thereby altering thus changing
87 the particle size spectrum, hygroscopicity, and radiative properties (Hsu et al., 2014;
88 Tian et al., 2021; Jiang et al., 2018). Jiang et al. (2018) observed a significant increase
89 ~~that the concentrations of~~ nitrate and sulfate concentrations during a dust period in
90 March 2010 in Shanghai. This elevation was attributed ~~were significantly elevated due~~
91 to the presence of moderate ~~to~~ high levels of relative humidity and gaseous precursors
92 ~~during a dust period in March, 2010 at Shanghai~~, implying that dust can efficiently
93 promoted the formation of sulfate and nitrate. ~~The formation of nitrate included two~~
94 ~~major pathways. During daytime, the OH radicals produced by the photolysis of O₃ and~~
95 ~~HONO oxidized NO₂ to produce HNO₃ (Hertel et al., 2012), which subsequently~~
96 ~~neutralized the alkaline substances to form nitrate in the particles. During nighttime~~

97 ~~with low temperature and high humidity, NO₂ can be oxidized by O₃ to form NO₃~~
98 ~~radical (Mentel et al., 1996), which then reacted with NO₂ to form N₂O₅-radical~~
99 ~~(Dall'osto et al., 2009; Petetin et al., 2016).~~ Previous studies have revealed that HNO₃
100 formed through the reactions of NO₂ with hydroxyl radical or N₂O₅ hydrolysis ~~would~~
101 preferentially react~~s~~ with mineral dust particles and produce nitrate, which ~~erves as the~~
102 ~~primary~~~~was the main~~ source of nitrate during ~~the dust period episodes~~ (Tang et al., 2016;
103 Wu et al., 2020). ~~Improvements in the simulation of sulfate were achieved by~~
104 ~~employing various parameterization schemes for the heterogeneous uptake of SO₂ on~~
105 ~~natural dust surfaces in the presence of NH₃ and NO₂ under different relative humidity~~
106 ~~conditions~~(Zhang et al., 2019)~~-. Wang et al. (2018) found-simulated that the~~
107 heterogeneous reactions on ~~the dust surface were the main sources~~~~accounted for the~~
108 ~~majority~~ of nitrate, ~~and the dust surface nitrate observed in Japan mainly formed~~ over
109 the Yellow Sea and the East China Sea during the ~~dust~~ long-range transport. ~~Tang et al.~~
110 (2017) ~~conducted a comprehensive review on the effect of dust heterogeneous reactions~~
111 ~~on the tropospheric oxidation capacity. They proposed that high RH (> 80%) and a~~
112 ~~wider range of temperature should be considered in the laboratory studies of~~
113 ~~heterogeneous reactions of mineral dust. Additionally, more comprehensive kinetic~~
114 ~~models should be developed to understand the complex multiphase reactions.~~
115 ~~Controversies have arisen regarding~~ However, ~~there were some controversies on the~~
116 mixing of dust and anthropogenic aerosols. Zhang et al. (2005) found that
117 anthropogenic aerosols separated with dust during a dust event in Qingdao, China.
118 Coincidentally, ~~there existed~~ a time-lag between dust and anthropogenic aerosols ~~was~~
119 ~~observed~~ in Japan and South Korea downstream of the dust transport. Single particle
120 analysis ~~revealed confirmed~~ that sulfate in fine particles appeared 12 hours before the

Formatted: Font: (Default) Times New Roman, 小四, Font color: Auto, Pattern: Clear

21 dust arrival in Japan. Wang et al. (2013) also observed a lag of 10 - 12 hours ~~lag~~ between
22 dust and anthropogenic aerosols ~~in-on~~ a dust day in Shanghai (Wang et al., 2013).
23 Furthermore, Huang et al. (2019) documented vertical differences in ~~observed that there~~
24 ~~were vertical differences of the~~ long-transported aerosols during a pollution event in
25 Taiwan. Dust from the Gobi Desert in Inner Mongolia and China existed at the altitudes
26 of 0.8km and 1.90km, respectively, while biomass burning aerosols from South Asia
27 ~~were present~~existed at higher altitudes of 3.5km.
28 Coastal regions often experience a mixture of inland anthropogenic emissions and
29 releases from the ocean, making regional pollution complex in these areas ~~In the coastal~~
30 ~~regions, the regional pollution was always a mix of inland anthropogenic emissions and~~
31 ~~ocean sourced releases. Due to the active human activities and special weather~~
32 ~~conditions such as monsoon and sea land breezes, the atmospheric compound pollution~~
33 ~~was usually more complex in the coastal areas~~ (Wang et al.; Hilario et al., 2020; Patel
34 and Rastogi, 2020; Perez et al., 2016; Wang et al., 2017). The eastern coast of China,
35 ~~is~~ bordering the East China Sea and the Yellow Sea, ~~and is~~ particularly strongly
36 influenced by the Asian monsoon and high emissions from inland industries, resulting
37 ~~in highly intricate. The~~ meteorological ~~conditions~~ and pollution conditions ~~in this~~
38 ~~region were among the most complex in the world~~ (Hilario et al., 2020). Furthermore,
39 the marine boundary layer in this region exhibits significant seasonal and diurnal
40 variations in, ~~Due to the complex meteorological conditions, the~~ relative humidity and
41 temperature ~~of the marine boundary layer showed significant seasonal and diurnal~~
42 ~~changes,~~ further impacting ~~affecting~~ the photochemical processes and ~~the~~
43 heterogeneous reactions on ~~the~~ aerosol surfaces (Zhao et al., 2021). Sea and land
44 breezes play a crucial role in this coastal area. During the night, land breezes carry

Font color: Auto, Pattern: Clear

Formatted: Font: (Default) Times New Roman, 小四,
Font color: Auto, Pattern: Clear

145 ~~pollutants from the land to the sea. Subsequently, during the day, these land breezes~~
146 ~~transform into sea breezes, bringing the pollutants back over the sea. This phenomenon~~
147 ~~leads to an increase in air pollutants over the land~~~~Under the influence of sea and land~~
148 ~~breezes, land breezes at night blew the land pollutants to the sea. In the next day, land~~
149 ~~breezes would evolve as sea breezes and return the pollutants over the sea to the land,~~
150 ~~resulting in the increase of air pollutants over the land~~ (Zhao et al., 2021). ~~For~~
151 ~~instance~~~~Meanwhile, Wang et al. (2022b) found that during the ozone pollution in~~
152 ~~Shanghai in 2018, the presence of O₃ at high altitudes at night was transported vertically~~
153 ~~downward during the daytime and high O₃ over the ocean was transported horizontally~~
154 ~~to the land, thus jointly causing~~~~contributing to regional O₃ pollution in Shanghai. Also,~~
155 ~~one dust episode in 2014 was observed over Shanghai via detouring from northern~~
156 ~~China due to the blocked north Pacific subtropical high-pressure system~~ (Wang et al.,
157 2018).
158 ~~High relative humidity caused by the sea breeze favored the participation of gaseous~~
159 ~~precursors in heterogeneous reactions, hygroscopic growth of particles, and secondary~~
160 ~~aerosol formation. Sun et al. (2020) found that nitrate was the main species of aerosol~~
161 ~~in Shanghai during pollution events from 2017–2018, while most of these events in~~
162 ~~winter were caused by the long transport of air pollutants from the North China Plain.~~
163 ~~Sea salt, as an important component of aerosol in coastal areas, has been found in~~
164 ~~various studies that complex multiphase reactions can occur on the surface of sea salts~~
165 (Huang et al., 2010b; Patel and Rastogi, 2020; Wang et al., 2022a). ~~Wang et al. (2022a)~~
166 ~~found that the addition of Na⁺ in the ISORROPIA model improved the simulation~~
167 ~~performance of aerosol and gaseous species at a coastal site in the South China Sea,~~
168 ~~indicating that sea salts participated in the heterogeneous reactions with other aerosol~~

Field Code Changed

69 species. Liang et al. (2018) found that the rise of O₃ in Shanghai could be affected by
70 both local secondary formation and marine transport based on observation and
71 simulation. Meanwhile, Wang et al. (2022b) found that during the ozone pollution in
72 Shanghai in 2018, the presence of O₃ at high altitudes at night was transported vertically
73 downward during the daytime and high O₃ over the ocean was transported horizontally
74 to the land, thus jointly causing regional O₃ pollution in Shanghai.

75 Previous studies have shown that about 70% of Asian dust ~~traverses would pass~~
76 ~~through~~ the eastern coast of China ~~before and then moving towards themoved out over~~
77 Korean Peninsula, ~~and~~ the Sea of Japan, ~~and eventually reaching finally ending at the~~
78 Pacific Ocean. The eastern coast of China ~~serves as a crucialis considered as the~~
79 ~~essential~~ route ~~of for the~~ Asian dust transport to the Pacific Ocean (Arimoto et al., 1997;
80 Huang et al., 2010a). ~~Most previous research has focused on typical dust events~~
81 ~~characterized by strong intensities, high wind speed, low humidity, and low oxidants~~
82 (Li et al., 2017; Ma et al., 2019; Xu et al., 2017; Xie et al., 2005). ~~In + In contrast, this~~
83 study ~~aims to depict,~~ an atypical dust event was observed in Shanghai, a coastal mega-
84 city in Eastern China. The unusualness of the meteorological conditions, ~~transport~~
85 ~~pathways,~~ and air pollutants during the ~~particular dust event~~ was explicitly described.
86 ~~The study involves categorizing the dust event into tThree stages of the dust were sorted~~
87 and ~~comparing the~~ aerosol chemical compositions ~~between these stages. were~~
88 ~~compared.~~ By focusing on the second and third stages, the different formation
89 mechanisms of nitrate and sulfate were investigated. The amounts of major aerosol
90 species from transport and secondary formation were estimated based on a ~~simplified~~
91 ~~simple~~ method of relating the upstream and receptor simultaneous measurements. ▲

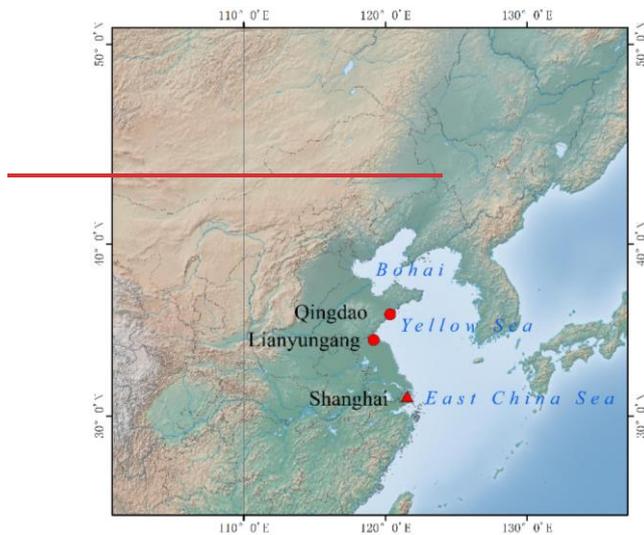

Figure 1. The observational sites in this study, including Shanghai, Qingdao, and Lianyungang.

2.2. Instrumentation

A set of online instruments was set up at the Pudong observational site. Inorganic ions (NO_3^- , SO_4^{2-} , Cl^- , Na^+ , NH_4^+ , K^+ , Mg^{2+} , Ca^{2+}) in $\text{PM}_{2.5}$ and soluble gases (NH_3 , HNO_3 , HCl , HONO) were measured by an online ion chromatography (IC, MARGA-1S, Metrohm). It operated at a flow rate of 16.7 L/min with a time resolution of one hour. Briefly, air was drawn into a $\text{PM}_{2.5}$ cyclone inlet and passed through a wet rotating denuder (gases) and a steam jet aerosol collector (aerosols). Subsequently, the aqueous samples were analyzed with ion chromatography. More details can be found in (Xu et al., 2020). Hourly trace metals (Si, Ca, Cu, Fe, K, Co, Mn, Cr, Zn, Pb, As, Cd, V, Ni) in $\text{PM}_{2.5}$ were measured by using the Xact 625 multi-metals monitor (Cooper Environmental, Beaverton, OR, USA). Particles were collected onto a Teflon filter tape at a flow rate of 16.7 L/min, and then transported into the spectrometer where the

Formatted: Justified, Indent: First line: 0 ch

226 particles were analyzed with an X-ray fluorescence. Organic carbon and elemental
227 carbon were measured by an in situ Semi-Continuous Organic Carbon and Elemental
228 Carbon aerosol analyzer (RT-4, Sunset Laboratory, Beaverton, Oregon, USA). The
229 concentration of mineral aerosols is calculated by summing the major mineral elements
230 with oxygen for their normal oxides, i.e., [Minerals]=
231 (2.2*Al+2.49*Si+1.63*Ca+2.42*Fe+1.94*Ti) (Malm et al., 1994). The concentration
232 of OM (organic matters) is estimated by multiplying OC with a factor of 2.

233 The concentrations of particles and gaseous pollutants were measured by a set of
234 Thermo Fisher Scientific instruments, including PM_{2.5} (Thermo 5030i), PM₁₀ (Thermo
235 5030i), SO₂ (Thermo Fisher 43i), NO_x (Thermo Fisher 42i), O₃ (Thermo Fisher 49i),
236 and CO (Thermo Fisher 48i-TLE). Meteorological parameters (ambient temperature,
237 relative humidity, wind speed, and wind direction) were obtained by a Vaisala Weather
238 transmitter (WXT520). Other supplementary parameters such as the height of planetary
239 boundary layer (PBL), vertical profiles of ozone and aerosol extinction were obtained
240 by a ceilometer (CL31, Vaisala), ozone lidar (LIDAR-G-2000, WUXIZHONGKE), and
241 aerosol lidar (AGJ, AIOFM), respectively.

242

243 **2.3. Thermodynamic simulation of aerosol pH and aerosol liquid water content**

244 The ISORROPIA II model is subject to the principle of minimizing the Gibbs energy
245 of the multi-phase aerosol system, leading to a computationally intensive optimization
246 problem (Song et al., 2018). ISORROPIA II calculates the aerosol pH, ALWC (aerosol
247 liquid water content) and compositions of ammonia-sulfate-nitrate-chloride-sodium-
248 calcium-potassium-magnesium in the thermodynamic equilibrium with gas-phase
249 precursors. The performances and advantages of ISORROPIA over the usage of other

250 thermodynamic equilibrium codes has been assessed in numerous studies (Nenes et al.,
251 1998; West et al., 1999; Ansari and Pandis, 1999; Yu et al., 2005). The ISORROPIA
252 running in the forward mode at the metastable state was applied in this study.

253

254 2.4. Hybrid Single-Particle Lagrangian Integrated Trajectory Model

255 The HYSPLIT (Hybrid Single-Particle Lagrangian Integrated Trajectory) was
256 used to compute the backward trajectories of the air parcels during the dust events. In
257 this study, the HYSPLIT model was driven by meteorological data outputs from the
258 Global Data Assimilation System (GDAS) (Su et al., 2015), which is available at
259 <ftp://arlftp.arlhq.noaa.gov/pub/archives/gdas1>. Air mass trajectories were launched at
260 different heights from the ground and a total duration of 48 hours simulation was
261 conducted.

262

263 2.5. Calculation of uptake coefficient of NH₃ (γ_{NH_3}) on particles

264 NH₃, being the most abundant alkaline species in the atmosphere, plays a crucial
265 role in acid neutralization and secondary aerosol formation. To assess the gas-particle
266 partitioning of NH₃, the uptake coefficient of NH₃ (γ_{NH_3}) on particles is calculated as
267 below. Initially, the quasi-first-order reaction rate constant for heterogeneous
268 conversion from NH₃ to NH₄⁺ (k_{het} , s⁻¹) is calculated according to (Liu et al., 2022).

$$269 k_{\text{het}} = \frac{2(C_{\text{NH}_4^+, t_2} - C_{\text{NH}_4^+, t_1})}{(C_{\text{NH}_3, t_2} + C_{\text{NH}_3, t_1})(t_2 - t_1)}$$

270

271 k_{het} is only valid when $c_{\text{NH}_4^+}$ increases, while c_{NH_3} decreases assuming a constant
272 emission rate from t_1 to t_2 (1 h in this study). Then, the uptake coefficient of NH₃ (γ_{NH_3})

273 on particles can be calculated as below (Liu et al., 2022; Wang and Lu, 2016).

274
$$\gamma_{\text{NH}_3} = \frac{4k_{\text{het}}}{S\omega} = \frac{4k_{\text{het}}}{S\sqrt{\frac{8RT}{\pi M}}}$$

275 where S is the surface area of particles (m² m⁻³) measured using SMPS and APS. ω is
276 the velocity of NH₃ molecules. T is the ambient temperature (K). R is the ideal gas
277 constant, and M is the molecular weight of NH₃ (kg mol⁻¹).

279 3. Results and Discussion

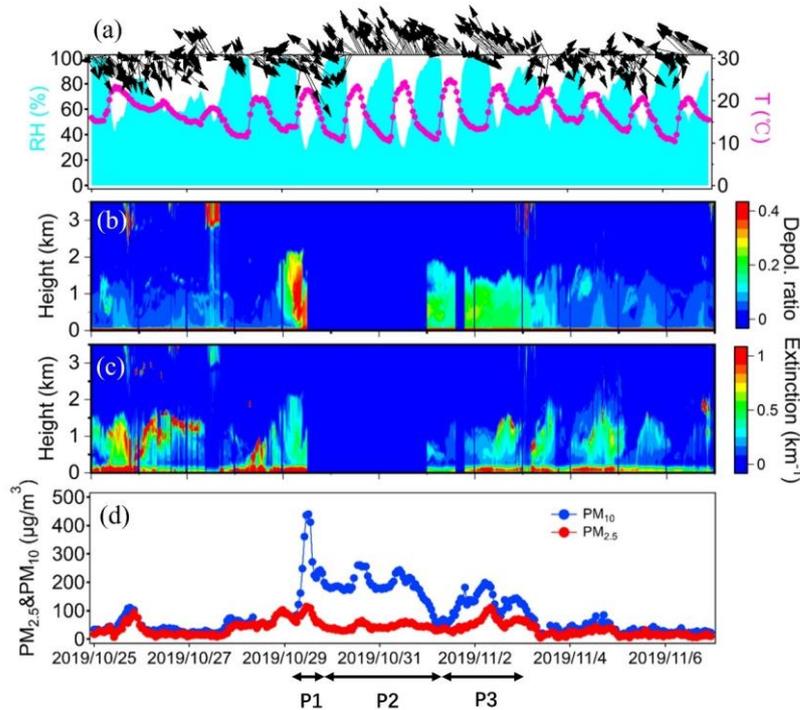

280 3.1. Characteristics of an unusual dust event

281 ~~Figure 2~~ Figure 1 shows the time series of PM₁₀, PM_{2.5}, ~~and~~ meteorological
282 parameters, as well as the vertical profiles of aerosol extinction coefficient and
283 depolarization ratio observed at the Shanghai sampling site from October 25 to
284 November 6, 2019. ~~During From~~ October 25 to 28, the mean wind speed remained was
285 relatively low of 0.9±0.72m/s with ~~the a~~ peak value of 3.1m/s, and predominantly
286 blowing winds prevailed from the northwest. The mean concentration of PM_{2.5} and
287 PM₁₀ was 34.7 and 44.2 µg/m³, respectively. Starting at 4:00 LST on October 29, the
288 concentration of PM₁₀ increased sharply and lasted till November 2 (Figure 12d). ~~Based~~
289 ~~on the~~ The aerosol lidar observation indicated that, both the aerosol extinction
290 coefficient and depolarization ratio extended from the ground to around 2km during the
291 same period. ~~Notably~~ Specifically, the enhanced depolarization ratio (>0.1) suggested
292 the occurrence of a prolonged dust event in Shanghai. was obviously enhanced (>0.1),
293 ~~indicating that Shanghai encountered a long-lasting dust event. Throughout the~~
294 ~~entire~~ During the whole dust period, the mean concentrations of PM_{2.5} and PM₁₀ reached
295 53.3 ± 20.5µg/m³ and 172.4 ± 70.2µg/m³, respectively, yielding a low PM_{2.5}/PM₁₀ ratio

296 of 0.34 ± 0.15 . As a comparison, $PM_{2.5}$ and PM_{10} during the non-dust period was
 297 $38.9\mu\text{g}/\text{m}^3$ and $49.8\mu\text{g}/\text{m}^3$, respectively, exhibiting with a relatively high $PM_{2.5}/PM_{10}$
 298 ratio of 0.62 ± 0.20 .

Formatted: Font: (Default) Times New Roman, 小四, Font color: Auto, Pattern: Clear

299
 300 Figure 12. Time series of (a) relative humidity, temperature, wind vectors, (b) aerosol
 301 depolarization ratio, (c) aerosol extinction coefficient, (d) mass concentrations of $PM_{2.5}$
 302 and PM_{10} during the study period. Three dust stages, i.e., P1, P2, and P3 are also marked.
 303 The missing aerosol lidar data were due to instrument malfunction.

304
 305 The occurrences of dust were are typically usually accompanied by low relative
 306 humidity and strong winds due to the passage of cold fronts (Huang et al., 2010b; Huang
 307 et al., 2010a; Wang et al., 2013; Wang et al., 2018). However, in in this study, relative
 308 humidity was exceptionally high with the mean value of $71 \pm 26\%$. It showed strong

Formatted: Font: (Default) Times New Roman, 小四, Font color: Text 1, Pattern: Clear

Formatted: Font: (Default) Times New Roman, 小四, Font color: Auto, Pattern: Clear

309 diurnal variation, ~~reaching with its~~ minimum in the daytime and even close to 100% in
310 the nighttime (Figure 12a). ~~Additionally, Also~~, wind speed was low of $0.54\pm 0.59\text{m/s}$
311 with a maximum of 2.6m/s . ~~Due to~~ This stagnant synoptic condition ~~led to elevated,~~
312 ~~the mean~~ concentrations of main gaseous pollutants such as O_3 , SO_2 , and NO_2 , ~~reached~~
313 ~~with mean values of~~ $86.0\pm 47.8\mu\text{g/m}^3$, $11.8\pm 3.4\mu\text{g/m}^3$, and $63.3\pm 27.9\mu\text{g/m}^3$,
314 respectively, even higher than those during the non-dust period.

315 We further divided the dust event into three stages based on the temporal
316 characteristics of PM_{10} and the ~~transport patterns of~~ air masses ~~transport patterns~~. As
317 shown in ~~Figure 2d~~ ~~Figure 1d~~, PM_{10} quickly climbed from 4:00 on October 29 and
318 reached a maximum of $436\mu\text{g/m}^3$ after 8 hours. The air masses ~~primarily~~ ~~mainly~~
319 originated from the semi-arid regions of northwest China (~~Figure 3d~~ ~~Figure 2d~~), ~~and~~
320 ~~this~~ ~~which~~ was consistent with both ~~the~~ near surface wind observation (~~Figure 2a~~ ~~Figure~~
321 ~~1a~~) and wind lidar observation (~~Figure 3a~~ ~~Figure 2a~~). The wind profiles showed
322 ~~prevailing dominant~~ northwest winds from the ~~surface up to ground to the altitudes of~~
323 around 2km before ~~the noon of on~~ October 29, indicating the presence of a strong
324 synoptic system. Afterwards, PM_{10} quickly decreased to $199\mu\text{g/m}^3$ at 20:00, October
325 29 within 8 hours. This was ~~primarily attributed~~ ~~mainly due~~ to the shift of wind
326 directions. As shown in ~~Figure 3a~~ ~~Figure 2a~~, ~~while although the~~ winds ~~at altitudes of~~
327 ~~higher than above~~ 700m ~~continued to blow~~ ~~kept blowing~~ from the northwest, ~~the near-~~
328 surface winds had ~~shifted~~ ~~turned~~ from the southeast. ~~Due to~~ ~~As~~ Shanghai's ~~is a~~ coastal
329 ~~city and~~ ~~location~~ adjacent to the East China Sea, the relatively clean southeasterlies
330 diluted the local air pollutants, ~~thereby explaining~~ ~~and thus explained~~ the quick ~~decline~~
331 ~~decrease of in~~ PM_{10} concentrations. This ~~initial short~~ dust episode ~~occurring from~~ 4:00
332 - 13:00, ~~on~~ October 29 was defined as Stage P1.

333 ~~Despite the persistent~~However, the prevailing southeasterly winds, the dust event
334 did not come to a complete halt, didn't fully terminate the dust event. Even under these
335 prevailing winds~~the persistent southeasterlies~~, hourly PM₁₀ concentrations remained
336 stayed above 150 µg/m³ until November 1, gradually decreasing and then decreased to
337 65 µg/m³ at 03:00, November 1 (Figure 2d1d). Compared to P1, wind speed during this
338 stage was as low as 0.4 ± 0.5m/s, while RH was moderately high of 70 ± 26%. Although
339 the daytime RH stayed low between 30% and 50%, it frequently soared above~~reached~~
340 over 90% at nighttime. Figure 3e-Figure 2e shows that although the air masses
341 originated from the Gobi Desert, they also traversed~~passed over~~ considerable coastal
342 regions. The wind profiles further indicated that while~~also showed that although~~
343 northwest winds prevailed at altitudes higher than 500m, the east and northeast winds
344 were dominant below 500m (Figure 3b2b). Consequently, This explained the relatively
345 high relative humidityRH during this period can be attributed to~~due to~~ the mixing
346 between-of dust plumes and-with coastal sea breezes. This dust episode from 14:00,
347 October 29 to 3:00, on November 1 was designated~~defined~~ as Stage P2.
348 Following After P2, PM₁₀ and PM_{2.5} rose again and peaked at 5:00 and 9:00, on
349 November 2 with the hourly concentration of 199 and 117µg/m³, respectively. Different
350 from P1 and P2, the air masses during this stage originated from the Shandong
351 Peninsula and the northern region of Jiangsu province, and then migrated over the
352 Yellow Sea and the East China Sea (Figure 3fFigure 2f). TypicallyUsually, the dust
353 plumes tend to travel eastward, would transport further eastwards and impacting the
354 western Pacific region and even distant faraway oceanic regions (Wang et al., 2018;
355 Nagashima et al., 2016). However, in this case, the air masses evidently deviated
356 deflected and pushed the dust back towards to the mainland. The wind profiles on

357 November 2 ~~revealed that also showed~~ winds ~~within at~~ the detected altitude range ~~of~~
 358 ~~altitudes, predominantly originated all came~~ from the eastern and southeastern oceanic
 359 regions (~~Figure 3e~~ ~~Figure 2c~~). This probably indicated the mixing between dust plumes
 360 and humid oceanic air masses was quite sufficient, which was also reflected by the
 361 highest average RH of $76 \pm 24\%$ among the three stages of the dust event. ~~Moreover,~~
 362 ~~in addition,~~ the concentrations of O_3 and NO_2 at this stage were higher than those of P1
 363 and P2, ~~potentially promoting which could be conducive to~~ the formation of secondary
 364 aerosol components and will be discussed later. This rarely observed dust backflow
 365 transport episode from 4:00, ~~on~~ November 1 to 23:00, ~~on~~ November 2 was
 366 ~~designated defined~~ as Stage P3.

367
 368 Figure 32. Wind profiles observed by a wind profiler radar on (a) October 29, (b)
 369 October 30, and (c) November 2. 48-hour backward trajectories simulated at the
 370 sampling site starting from (d) 4:00 AM, October 29, (e) 9:00 AM, October 30, and (f)
 371 13:00 PM, November 2. The red, blue, and green trajectories represented starting
 372 altitudes of 100, 500, and 1500m, respectively.

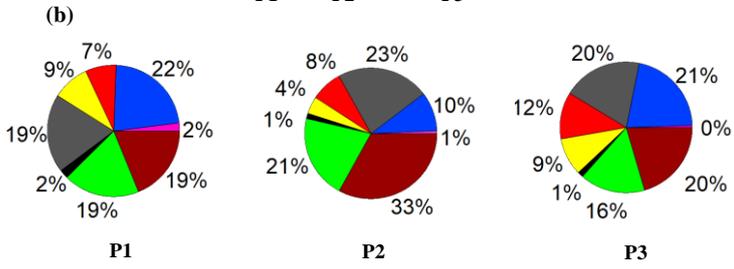

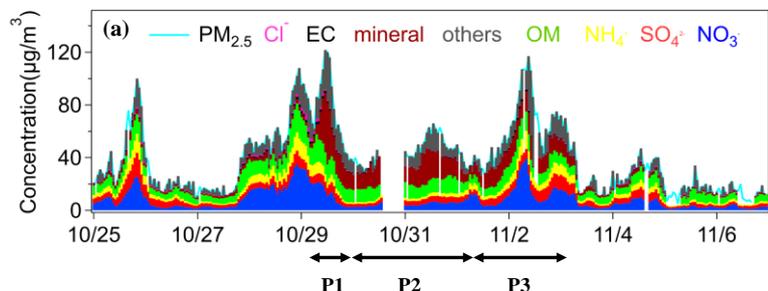

373

374 3.2. Comparisons of aerosol chemical compositions among the three dust stages

375 Figure 34a shows the time-series of hourly aerosol chemical components,
376 including SNA (NO_3^- , SO_4^{2-} , and NH_4^+), OM (~~organic matters = 2*OC~~), EC, and
377 mineral aerosols (~~[Minerals] = (2.2*Al+2.49*Si+1.63*Ca+2.42*Fe+1.94*Ti)~~, (Malm-
378 ~~et al., 1994))~~ in $\text{PM}_{2.5}$. During P1, the mean concentration of SNA was 49.9 ± 31.6
379 $\mu\text{g}/\text{m}^3$. The mineral aerosols reached $16.4 \pm 14.6 \mu\text{g}/\text{m}^3$, accounting for 19% in $\text{PM}_{2.5}$.
380 The contribution of OM to $\text{PM}_{2.5}$ was almost identical to that of mineral aerosols
381 (Figure 4b3b).

382
383

384
385

Figure 43. (a) Times-series of major chemical components in PM_{2.5} during the study

386 period. (b) The mean proportion of major chemical components in PM_{2.5} during the
387 three dust stages. ~~(c) Enrichment factors of elements in PM_{2.5} during the three dust~~
388 ~~stages.~~

389

390 During P2, mineral aerosols increased to 23.4±54.1 μg/m³ and accounted for 33%
391 in PM_{2.5}, representing the highest among all three stages (~~Figure 4b~~Figure 3b). Due to
392 the continuous dilution effect of dust on local anthropogenic pollutants, the
393 concentrations and proportions of SNA in PM_{2.5} were the lowest during this stage. For
394 instance, NO₃⁻ only accounted for 10% in PM_{2.5}, indicating a suppression of the nitrate
395 ~~formation of nitrate was suppressed to a certain~~some extent. The levels of OM didn't
396 ~~exhibit show~~ obvious changes and averaged 10.1±2.1 μg/m³, accounting for 21% in
397 PM_{2.5}.

Formatted: Font: (Default) Times New Roman, 小四, Font color: Text 1, Pattern: Clear

Formatted: Font: (Default) Times New Roman, 小四, Font color: Text 1, Pattern: Clear

Formatted: Font: (Default) Times New Roman, 小四, Font color: Text 1, Pattern: Clear

398 During P3, mineral aerosols averaged 11.9±2.7 μg/m³, ranking the lowest among
399 all three stages. The proportion of mineral aerosols in PM_{2.5} decreased to 20%,
400 suggesting the dust backflow from the ocean was less enriched in mineral components.
401 Compared to P2, SNA showed significant increases and much stronger diurnal
402 variations during P3. SO₄²⁻, NO₃⁻, and NH₄⁺ averaged 6.7 ± 2.4, 12.4 ± 8.9, and 5.4 ±
403 2.7 μg/m³, respectively. As shown in ~~Figure 4b~~Figure 3b, the contribution of nitrate to
404 PM_{2.5} increased to 21%, while that of sulfate rose to 12%, the highest among all three
405 stages. The concentration of OM (9.3±3.2 μg/m³) and its proportion (16%) ~~of OM~~
406 during P3 were lower than the other two stages, likely which was probably due to the
407 ~~unconventional unusual~~ dust backflow transport pathway.

Formatted: Font: (Default) Times New Roman, 小四, Font color: Auto, Pattern: Clear

Formatted: Font: (Default) Times New Roman, 小四, Font color: Auto, Pattern: Clear

408 ~~Enrichment factors (EFs) of the measured elements in PM_{2.5} were calculated by~~
409 ~~using Al as a reference element, i.e., $EF_x = (X/Al)_{\text{aerosol}} / (X/Al)_{\text{crust}}$, where X was the~~
410 ~~element of interest. As shown in Figure 4c, elements such as Si, Fe, and Ca were less~~

411 ~~enriched as they mainly derived from the crust. While for anthropogenic elements~~
412 ~~including Cu, Zn, Pb, As, Cd, Sb, and Se, they were enriched by different extents with~~
413 ~~EFs between 10 and 10,000. In addition, these elements above were more enriched~~
414 ~~during P1 than P2 and P3. The dust transport pathway via inland areas during P1 should~~
415 ~~be the main cause as anthropogenic sources such as metallurgical industries, coal fired~~
416 ~~plants, and smelters were widely located in inland regions. Exceptions were found for~~
417 ~~Ni and V, which were often used as tracers for heavy oil combustion. EFs of Ni and V~~
418 ~~exhibited higher values during P3 than P1 and P2. Since the dust backflow transport~~
419 ~~pathway during P3 had almost two days travelling durations over the East China Sea,~~
420 ~~which was on the one of the busiest international shipping trade routes (Fan et al., 2016),~~
421 ~~the enrichments of Ni and Vi were probably ascribed to the mixing between dust and~~
422 ~~marine shipping emissions.~~

423

424 **3.3. Unconventional features of the dust episodes**

Formatted: Font: 小四, Bold

425 ~~3.3.1. Effect of **Unusually enhanced high O₃ on the formation of secondary**~~ 426 ~~**aerosols during P2 dust**~~

427 Figure ~~5-4~~ shows the hourly near surface ozone concentrations and vertical
428 profiles of ozone during the study period. Interestingly, a few high O₃ peaks occurred
429 during the dust event (Figure ~~45~~a). O₃ averaged $92.8 \pm 52.8 \mu\text{g}/\text{m}^3$ during the dust,
430 about 50% higher than the non-dust days. Among the three dust stages, O₃
431 substantially increased from $35.9 \pm 36.4 \mu\text{g}/\text{m}^3$ during P1 to $80.7 \pm 41.2 \mu\text{g}/\text{m}^3$ during
432 P2, and ~~further rose to~~ $104.0 \pm 48.7 \mu\text{g}/\text{m}^3$ during P3. The low O₃ during P1 ~~can be~~
433 ~~attributed was due~~ to the cleansing effect of ~~the~~ strong dust associated with the ~~strong-~~
434 cold front, which was ~~consistent with similar as~~ previous studies that ~~reported~~

Formatted: Font: (Default) Times New Roman, 小四,
Font color: Auto, Pattern: Clear

Formatted: Font: (Default) Times New Roman, 小四,

Formatted: Font: (Default) Times New Roman, 小四,
Font color: Auto, Pattern: Clear

435 ~~reduced low~~ oxidants concentrations ~~were usually observed~~ during ~~intense strong~~ dust
436 events (Benas et al., 2013). ~~Regarding As for~~ the relatively high O₃ during P2 and P3,
437 several causes may ~~contribute to this phenomenon~~ ~~be responsible~~. Firstly, the mean
438 wind speed was low of 0.4 and 0.6 m/s during P2 and P3, respectively.

439 ~~Consequently Thus~~, this weak synoptic system exerted ~~a~~ weak dilution effect on the
440 local air pollutants. ~~A numerical study conducted during a similar period suggested~~
441 ~~that the reduction of boundary layer height and the warming of the lower atmosphere~~
442 ~~accelerated the ozone formation by ~1 ppbv/h~~ (Wang et al., 2020). Secondly, since
443 the dust plume travelled mostly over the coastal and oceanic areas, ~~a portion part of~~
444 O₃ could be transported from the high ozone oceanic areas (Wang et al., 2022b).

445 Thirdly, the ~~ozone lidar also detected observed~~ high O₃ stripes during P2 and P3. As
446 shown in Figure 5b, the high O₃ profiles extended from the surface to around 1km and
447 the profile structure was similar to that of aerosol depolarization ratio. The subsidence
448 of dust particles ~~likely contributed to downward transport of~~ ~~probably down drafted~~
449 high-altitude O₃, ~~thereby influencing and also contributed to the~~ ~~elevated high~~ O₃ near
450 the ground (Yang et al., 2022).

 453 height (b) Vertical profiles of ozone observed by the ozone Lidar.

454

455 ~~To investigate the effect of the relatively high O₃ on the formation of secondary~~
 456 ~~aerosols, Figure 6 displays the relationship between sulfate/nitrate and ammonium. The~~
 457 ~~strong correlations of sulfate-ammonium ($R^2=0.91$) and nitrate-ammonium ($R^2=0.93$)~~
 458 ~~were expected. The scatters were further color-coded by O₃ and it could be seen that~~
 459 ~~higher sulfate, nitrate, and ammonium tended to be formed under higher O₃~~
 460 ~~concentrations, suggesting the potential role of photochemistry in promoting the~~
 461 ~~formation of secondary aerosols.—~~

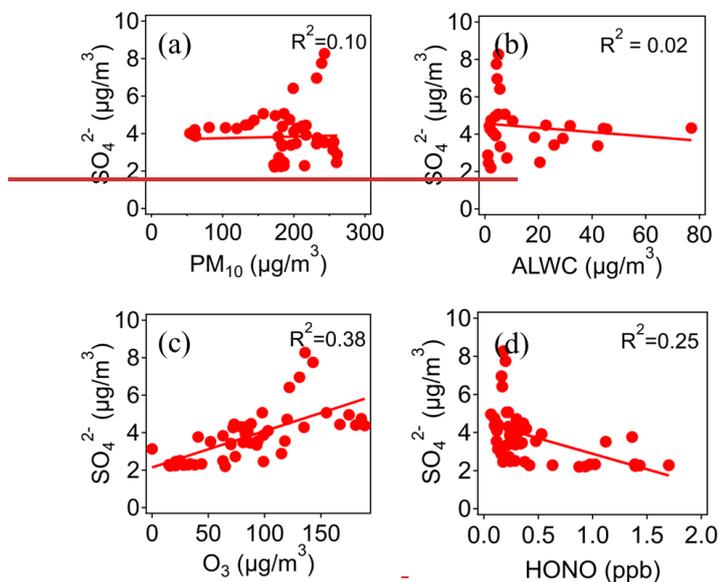

462

463 Figure 6. Linear relationship between sulfate/nitrate and ammonium with scatters
 464 colored by the concentrations of O₃ during P2

465

466 Figure 7 displays the linear relationship between sulfate and PM₁₀, ALWC, O₃,
 467 and HONO, respectively. Obviously, sulfate had no correlation with PM₁₀ (Figure 7a),
 468 indicating that dust contributed negligibly to sulfate. Also, sulfate had almost no or even
 469 a weakly negative correlation with ALWC (Figure 7b), suggesting aqueous-phase
 470 processing was not a major reaction pathway of secondary aerosols during P2. In
 471 contrast, we found that sulfate correlated positively with O₃ (R²=0.38, Figure 7c) and
 472 negatively correlated with HONO (R²=0.25, Figure 7d). It was well recognized that
 473 HONO was an important precursor to OH radical and it was estimated that HONO
 474 accounted for 30%–60% of the OH budget in Shanghai (Bernard et al., 2016). The
 475 moderate correlations between sulfate and O₃/HONO corroborated the discussion
 476 above that the formation of secondary aerosols during P2 should be mainly promoted
 477 via the gas-phase oxidations.

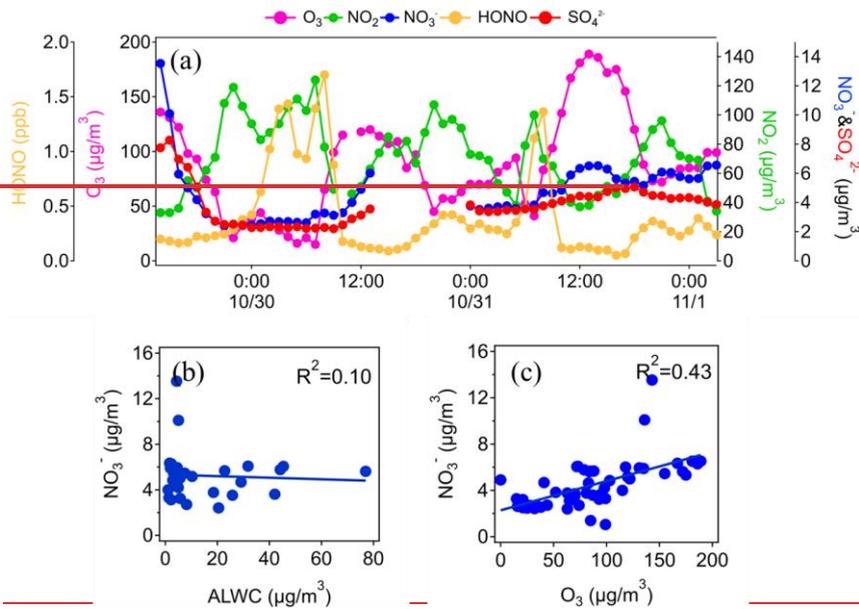

478

479 Figure 7. Linear relationship between sulfate and (a) PM_{10} , (b) ALWC, (c) O_3 , and (d)
480 HONO during P2

481

482 As similar as sulfate, nitrate didn't show correlation with ALWC (Figure 8b) but
483 moderately correlated with O_3 ($R^2=0.43$, Figure 8c). Figure 8a displays the temporal
484 variation of NO_2 , O_3 , HONO, and NO_3^- during P2. It can be found that although NO_2
485 was high at night as well as for HONO, the concentrations of NO_3^- were relatively low,
486 indicating a low formation potential of secondary aerosols. Figure 2a shows that RH
487 during P2 was relatively low at nighttime with a minimum of 31%, suggesting the
488 aqueous reactions could be suppressed to some extents. During the daytime, O_3 reached
489 its maximum while HONO reached its minimum, both contributing to the high levels
490 of oxidants. The co-variation of nitrate and sulfate with O_3 (Figure 8a) confirmed that
491 although dust often suppressed the formation of atmospheric oxidants, the
492 photochemistry reactions under unusually high O_3 concentrations dominated the

493 formation of sulfate and nitrate during P2 in this study.

494
495 **Figure 8. (a) Temporal variations of O₃, NO₂, HONO, nitrate, and sulfate during P2.**

497

498 3.4. Aerosol chemistry under dust backflows during P3

499 3.4.1. Evidence of ~~3.3.2. Dust backflows~~ during P3

500 The dust during P3 was diagnosed as a backflow transport pathway from the
501 mainland to Shanghai through the Yellow Sea and the East China Sea, as determined
502 by according to the backward trajectory analysis (~~Figure 3f~~Figure 2f). This
503 unconventional atypical dust transport route, termed pathway observed in this study
504 was defined as the "dust backflow", was consistent with a similar occurrence, in 2014
505 when dust from northern China detoured over Shanghai (Wang et al., 2018). In this
506 section, we have provided further more evidences of the dust backflow from various
507 aspects.

508 ~~Figure 3f~~ ~~Figure 2f~~ illustrates that shows the dust drifted away from the Shandong
 509 Peninsula, thus we selected two coastal sites in Shandong province for supplementary
 510 analysis. ~~Figure 9~~ ~~Figure S2~~ compares the time-series of hourly air pollutants at
 511 Qingdao, Lianyungang, and Shanghai. At Qingdao and Lianyungang, high PM₁₀
 512 concentrations were observed during October 30 – 31, indicating the invasion of dust
 513 ~~in these regions~~. After about two days, PM₁₀ ~~showed a peaked in Shanghai at on~~ early
 514 November 2 ~~at Shanghai~~. ~~This temporal consistency aligned~~ ~~This was consistent~~ with
 515 ~~the simulation duration of the backward trajectories, which lasted i.e.,~~ around 48 hours
 516 (Figure 23f). In Figure 9, it ~~can be observed~~ ~~could be seen~~ that in the ~~upstream~~ dust
 517 ~~upstream~~ regions (i.e., Qingdao and Lianyungang), PM₁₀ varied negatively with NO₂
 518 and CO (the highlighted period in the figure). While in Shanghai, positive correlations
 519 between PM₁₀ and ~~both~~ NO₂ (R²=0.32) ~~as well as between PM₁₀ and~~ CO (R²=0.55)
 520 indicated that the dust during P3 ~~served had acted~~ as a carrier ~~of the for~~ gaseous
 521 ~~pollutants rather than acting but not a diluter~~.

524 The dust periods at these three sites are highlighted.

525

526 More evidence of dust backflows was provided from the perspective of aerosol
527 chemical tracers. As discussed in Section 3.2, enrichment factors of V and Ni were the
528 highest during P3. Figure 10a further displays the time series of V and Ni and they
529 varied significantly during the study period. The mass concentrations of V and Ni
530 increased 4 and 1.8 times during P3 compared to P2, respectively. This indicated that
531 the dust had mixed with pollutants from marine vessel emissions and transported back
532 to Shanghai.

533

534 Figure 10. Time series of (a) V, Ni, (b) Ca, and Ca²⁺ during the study period

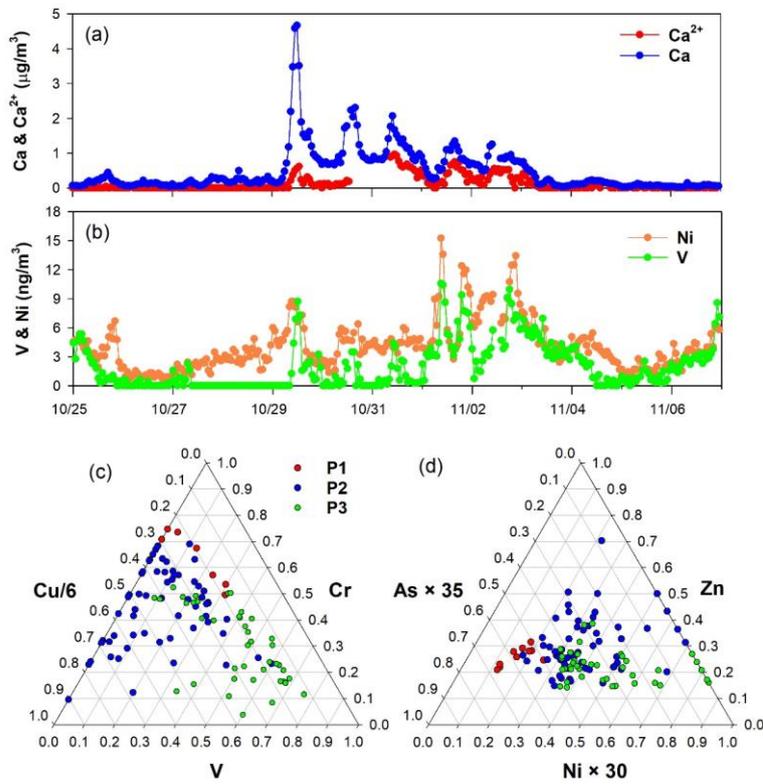

Figure 5. Time-series of (a) Ca, Ca²⁺, (b) V, and Ni during the study period. (c) Cu-Cr-V ternary diagram and (d) As-Zn-Ni ternary diagram among the P1 – P3 dust episodes. Due to substantial concentration differences of various elements, some elements are artificially changed to make most scatters appear around the centroid.

Formatted: Caption, Centered, Space Before: 9.5 pt, After: 9.5 pt

Additional ~~More~~ evidence of dust backflows was provided from the perspective of aerosol chemical tracers. ~~Figure 10b~~ Figure 5a plots the time-series of Ca and Ca²⁺, which represent~~ing~~ the total calcium and the soluble part of calcium, respectively. It was observed that Ca and Ca²⁺ didn't exhibit quite a proportional variation trend, which

Formatted: Font: (Default) Times New Roman, 小四, Font color: Auto, Pattern: Clear

545 should be related to the solubility of calcium during different dust stages. During P1,
546 the mean concentration of Ca reached the highest of $1.63 \pm 1.53 \mu\text{g}/\text{m}^3$ while Ca^{2+} was
547 the lowest of $0.21 \pm 0.20 \mu\text{g}/\text{m}^3$, thus resulting in the lowest Ca^{2+}/Ca ratio of 0.10 ± 0.08 .
548 As discussed in Section 3.1, dust during P1 was the strongest and thus it contained
549 higher fractions of minerals, ~~primarily which were mainly~~ in the form of insoluble metal
550 oxides. ~~The~~ average concentrations of Ca^{2+} and Ca during P2 were $0.33 \pm 0.28 \mu\text{g}/\text{m}^3$
551 and $1.11 \pm 0.46 \mu\text{g}/\text{m}^3$, ~~respectively, resulting in~~ the higher Ca^{2+}/Ca ratio of $0.27 \pm$
552 0.20 . As a comparison, the average concentrations of Ca^{2+} and Ca during P3 reached
553 $0.34 \pm 0.20 \mu\text{g}/\text{m}^3$ and $0.78 \pm 0.27 \mu\text{g}/\text{m}^3$, ~~respectively,~~ yielding the highest Ca^{2+}/Ca ratio
554 of 0.38 ± 0.19 . The ~~significantly much~~ higher solubility of calcium during P3 should be
555 directly related to the ~~prolonged presence lingerer~~ of dust plumes over the open ocean.
556 The abundant water vapor over the ocean could accelerate the dissolution of the
557 insoluble components in particles during the mixing between continental dust and
558 oceanic air masses. ~~Additionally, the backflow transport pathway facilitated the~~
559 ~~entrainment of sea salts and contributed to the increase of soluble calcium.~~
560 ~~As discussed in Section 3.2, enrichment factors of V and Ni were the highest~~
561 ~~during P3. Figure 10a5b provides additional insights by displaying further displays the~~
562 ~~time-series of V and Ni, which are typical tracers of oil combustions (Becagli et al.,~~
563 ~~2012), and t~~ They varied significantly during the study period, ~~and t~~ the mass
564 concentrations of V and Ni increased 4 and 1.8 times during P3 compared to P2,
565 respectively. This indicated that the dust had mixed with pollutants from marine vessel
566 emissions and transported back to Shanghai. ~~Consistently, the enrichment factors of Ni~~
567 ~~and V displayed higher values during P3 than P1 and P2 (Figure S3). The trends are~~
568 ~~substantiated in the ternary diagrams, which are commonly applied to illustrate the~~

569 relative abundances of three components and infer the source variations (Bozlaker et
570 al., 2019; Cwiertny et al., 2008; Laskin et al., 2005). As shown in the Cu-Cr-V ternary
571 diagram (Fig. 5c), the dust samples during P1 were positioned away from the V-apex.
572 As a comparison, the dust samples during P2 exhibited greater scattering, manifesting
573 enhanced anthropogenic contributions, e.g., from chrome plating industries (Hammond
574 et al., 2008). Compared to P2, the dust samples during P3 moved toward the V-apex,
575 indicating a higher contribution from oil combustions (Becagli et al., 2012). A similar
576 pattern was observed in the As-Zn-Ni ternary diagram (Fig. 5d). The majority of dust
577 samples during P2 spanned across the diagram, reflecting contributions from mixed
578 anthropogenic sources. Reciprocally, P3 was closer to the Ni-apex. These lines of
579 evidences collectively confirmed that the dust had mixed with pollutants from marine
580 vessel emissions over one of the busiest international shipping trade routes (Fan et al.,
581 2016) and was subsequently transported back to Shanghai.

583 **3.4. Formation of secondary aerosols during the dust long-range transport**

Formatted: Font: Bold

584 **3.4.1. Comparison of typical chemical tracers**

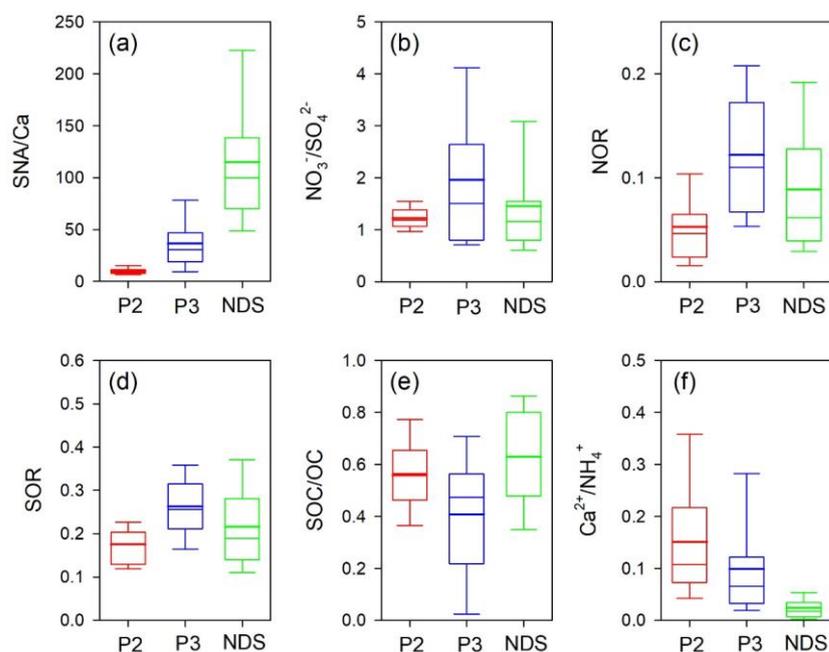

Figure 6. Box plots of (a) SNA/Ca, (b) $\text{NO}_3^-/\text{SO}_4^{2-}$, (c) NOR, (d) SOR, (e) SOC/OC, and (f) $\text{Ca}^{2+}/\text{NH}_4^+$ during P2, P3, and NDS, respectively.

To delve deeper into the formation characteristics of secondary aerosols in different stages, a variety of chemical tracers was investigated. The P1 dust stage was excluded from statistical analysis due to its short duration and limited data availability. Fig. 6a shows the comparison of SNA/Ca ratios during P2, P3 and non-dust days (NDS). The SNA/Ca ratio can be used to assess the relative changes between secondary production and primary dust emission by eliminating the impact of meteorological conditions among different periods (Zheng et al., 2015). Compared to the two dust episodes, the SNA/Ca ratio is significantly higher during NDS. This can be attributed to the much lower concentrations of mineral aerosols during NDS, thus resulting in the

598 higher SNA relative to Ca. In terms of comparing P2 and P3, the average SNA/Ca ratio
599 during P3 was 3 times that of P2, indicating that the formation of secondary inorganic
600 aerosols was more prominent during the dust backflow. Regarding the $\text{NO}_3^-/\text{SO}_4^{2-}$ ratios
601 (Fig. 6b), they were close between NDS and P2, with NO_3^- slightly exceeding SO_4^{2-} .
602 The range of $\text{NO}_3^-/\text{SO}_4^{2-}$ was the largest during P3 with a mean value of around 2,
603 suggesting that the dust backflow was more conducive to the accumulation of nitrate.
604 The nitrogen oxidation ratio ($\text{NOR} = \text{NO}_3^-/(\text{NO}_3^- + \text{NO}_2^-)$) and the sulfur oxidation ratio
605 ($\text{SOR} = \text{SO}_4^{2-}/(\text{SO}_4^{2-} + \text{SO}_2)$) were further used to gauge the extent of nitrate and sulfate
606 formation, both showing trends of $\text{P3} > \text{NDS} > \text{P2}$ (Fig. 6c & 6d). It should be noted that
607 NOR and SOR cannot be used to realistically characterize the extent of nitrogen and
608 sulfur oxidation during transport-dominated pollution cases, as upstream aging aerosols
609 can significantly increase the above ratios (Ji et al., 2018). In the following discussion,
610 we will focus on the formation mechanism of SNA during different dust stages.

611 The results of SOC/OC ratios differed from the above analysis that SOC/OC was
612 lower during P3 than during P2 and NDS (Fig. 6e), suggesting that the formation of
613 secondary organic aerosols was not favored via the dust backflow. This may be due to
614 its maritime transport pathway as the emission intensity of volatile organic compounds
615 from the ocean is much lower than that from land sources. Consequently, the lacking
616 of organic aerosol precursors could be the main cause for the lower SOC/OC ratios
617 during P3. Finally, the $\text{Ca}^{2+}/\text{NH}_4^+$ ratio was employed to assess the relative
618 contributions of alkaline chemical components (Fig. 6f). As expected, this ratio during
619 the two dust stages was much higher than that of NDS, indicating the important
620 contribution of dust to alkaline metal ions. The $\text{Ca}^{2+}/\text{NH}_4^+$ ratio was higher during P3
621 (0.15) than during P2 (0.10), which aligned with the findings presented in Section 3.2.

635 and NO₃⁻ displayed the most significant correlations with O₃ and Ox (O₃+NO₂), while
636 even negatively correlated with ALWC. In regard of the obvious ozone enhancement
637 phenomenon as discussed in Section 3.3.1, photochemistry should be the main pathway
638 for the secondary aerosol formation rather than the liquid phase processing. In addition,
639 SO₄²⁻ and NO₃⁻ also showed moderate correlations with elemental Ca, suggesting that
640 dust acted as a carrier to transport these salts, which can be derived from background
641 minerals in dust (Wu et al., 2022) and dust heterogeneous reactions during the transport
642 (Huang et al., 2010a).

643 As for P3, it showed a distinctly different correlation heatmap from P2. While
644 SO₄²⁻ still demonstrates a correlation with O₃, the relationship between NO₃⁻ and O₃
645 (as well as Ox) disappeared. On the contrary, both SO₄²⁻ and NO₃⁻ show significant
646 correlations with ALWC. During P3, the average RH reached 76%, providing favorable
647 conditions for liquid-phase reactions. Furthermore, by relating NO₃⁻ and the
648 multiplication of ALWC and NO₂, the correlation coefficient (R² = 0.41) was further
649 improved (Figure S4a). Similar results were observed by relating NO₃⁻ to the
650 multiplication of ALWC and NO₂*O₃*NO₂ (a proxy of N₂O₅, (Huang et al., 2021))
651 (Figure S4b), confirming the dominant reaction pathway of nitrogen oxides to nitrate
652 via the aqueous phase reactions. As a result, NO₃⁻ was also strongly correlated with
653 HONO (Figure S4c), typically deriving from the heterogeneous reactions of NO₂ on
654 the surface of moist particles (Alicke et al. (2002)).

- Formatted
- Formatted
- Field Code Changed
- Formatted
- Field Code Changed

655 In addition, unlike P2, both SO₄²⁻ and NO₃⁻ showed moderate to significant
656 correlations with Na⁺. Since neither SO₄²⁻ nor NO₃⁻ correlated with Ca, it can be inferred
657 that sea salts played a more important role in the transport of air pollutant during the
658 dust backflow over the ocean. To assess whether dust or sea salts participated in the

- Formatted

659 heterogeneous reactions of secondary aerosol during P3, the ISORROPIA II model was
660 run with different scenarios. Figure S5 shows the model performance for SO_4^{2-} , NO_3^- ,
661 NH_4^+ , and NH_3 based on the SO_4^{2-} - NO_3^- - NH_4^+ - Cl^- - NH_3 - HCl - HNO_3 system. After
662 adding Ca^{2+} into this thermodynamic equilibrium system, the correlations between the
663 simulations vs observations for all four species were lowered with different extents
664 (Figure S6). If Na^+ was added into the thermodynamic equilibrium system, the model
665 performance was slightly improved (Figure S7). This corroborated that the
666 heterogeneous reactions on dust were very limited while sea salts were intensively
667 involved in the formation of secondary inorganic aerosols during the dust backflow.

668 To further explore the influencing factors affecting the formation of secondary
669 inorganic aerosols, we examined the role of NH_3 in different stages, representing by the
670 relationship between the gas-particle partitioning of ammonia ($\varepsilon(\text{NH}_4^+)$, defined as the
671 ratio between particle phase ammonia (NH_4^+) and total ammonia ($\text{NH}_x = \text{NH}_3 + \text{NH}_4^+$))
672 and the total acids ($\text{SO}_4^{2-} + \text{NO}_3^-$). As shown in Figure 7c, it is obvious that the total
673 acids strongly co-varied with $\varepsilon(\text{NH}_4^+)$. Higher $\varepsilon(\text{NH}_4^+)$ resulted in higher
674 concentrations of secondary aerosols. Moreover, under similar $\varepsilon(\text{NH}_4^+)$ conditions,
675 higher NH_3 promoted stronger formation of secondary aerosols. Thus, both NH_3 and
676 $\varepsilon(\text{NH}_4^+)$ collectively determined the aerosol formation potential. The mean states of
677 P2, P3, and NDS are compared in Figure 7c. P2 had the lowest $\varepsilon(\text{NH}_4^+)$ with the mean
678 value of 0.21, despite the relatively high concentrations of NH_3 during this period (7.9
679 $\pm 1.0 \mu\text{g}/\text{m}^3$). The relatively low gas-particle partitioning of ammonia limited the
680 neutralization of the acidic components. In contrast, NH_3 during P3 was the highest
681 during the study period ($9.8 \pm 1.8 \mu\text{g}/\text{m}^3$), and $\varepsilon(\text{NH}_4^+)$ (0.34) was only slightly lower
682 than that during NDS, thus effectively fostering the formation of secondary inorganic

683 aerosols.

684 To explain this phenomenon, the uptake coefficient of NH₃ (γ_{NH_3}) on particles,
685 which is one of the important parameters affecting the gas-particle partitioning of
686 ammonia, was calculated. Figure 7d shows the decreasing trend of γ_{NH_3} with the
687 increase of dust intensity (using Ca as an indicator). This coincided with a multi-year
688 observational study in Beijing and Shijiazhuang, where γ_{NH_3} obviously increased due
689 to significant decline in alkali earth metal contents from the dust emission sources
690 during 2018 – 2020 (Liu et al., 2022). Thus, this partially explained why $\varepsilon(\text{NH}_4^+)$ was
691 relatively low during P2, which was ascribed to the reduced uptake capacity of NH₃ on
692 particles.

693 The ion balance calculation indicated that the total anions and cations are in ideal
694 equilibrium (Figure S8, regression slope = 0.99, $R^2 = 0.99$), indicating that both NH₄⁺
695 and alkali metal cations (including Na⁺, K⁺, Mg²⁺, and Ca²⁺) contributed to the
696 neutralization of acids to varying degrees. The ratio of alkali metal cations/total anions
697 (AMC/TA) was used to color the data points in Figure 7d, showing an opposite trend
698 between AMC/TA and γ_{NH_3} . During P2, the mean value of AMC/TA reached 21%,
699 implying that the neutralization of acids by NH₃ had been significantly suppressed, thus
700 explaining the decrease in the NH₃ uptake coefficient at high dust intensity. In contrast,
701 the AMC/TA ratio decreased to 11% during P3, indicating a reduced competition
702 between NH₃ and the alkali dust components. Finally, we also compared the aerosol pH
703 at different stages, which was 3.2, 3.0, and 2.8 during P2, P3, and NDS, respectively.
704 The relatively high aerosol acidity at P3 and NDS favored the uptake of alkaline gases
705 (Liu et al., 2022), which also contributed to the higher (γ_{NH_3}) at these two stages.

3.4.2. Formation processes of secondary aerosols during P3

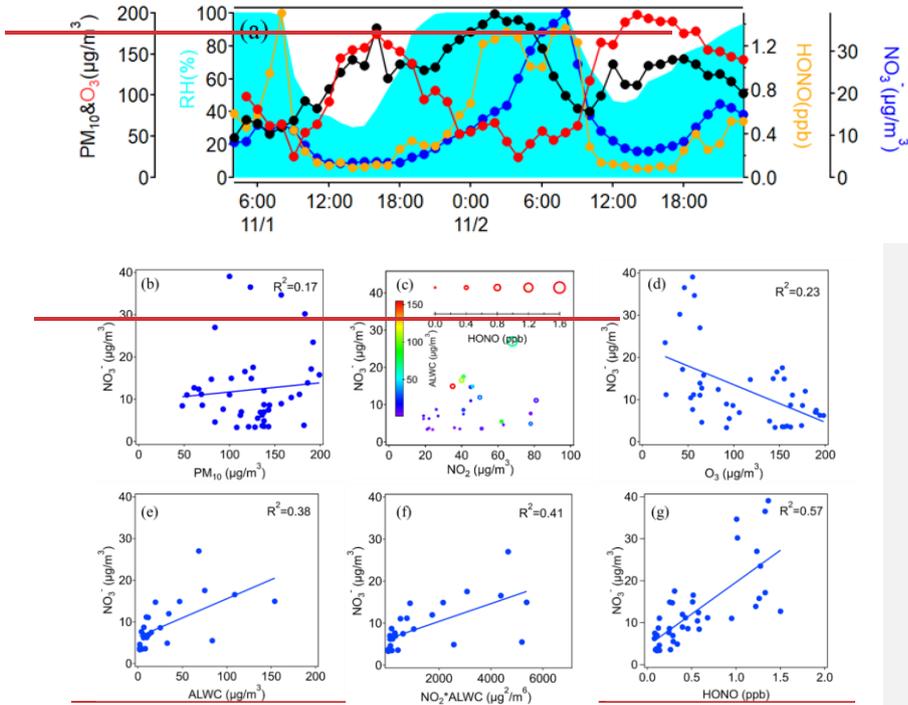

Figure 11. (a) Time series of PM_{10} , NO_3^- , O_3 , HONO, and RH during P3. Linear relationship between nitrate and (b) PM_{10} , (c) NO_2 , (d) O_3 , (e) ALWC, (f) $NO_2 \cdot ALWC$, and (g) HONO.

In this section, the main processes that dominated the formation of secondary aerosols during P3 were probed and compared to P2. Figure 11a shows the time series of hourly PM_{10} , NO_3^- , O_3 , HONO, and RH during P3. It could be visualized that most parameters co-varied relatively consistently to some extent. Different from P2, nitrate showed weak correlation with PM_{10} (Figure 11b), indicating that part of nitrate could be directly transported via the dust transport. Also different from P2, nitrate even showed negative correlation with O_3 (Figure 11d). From Figure 11a, nitrate

721 concentrations were at its troughs during daytime when O₃ peaked. Thus,
722 photochemical reactions didn't play an important role in the formation of nitrate during
723 this stage.

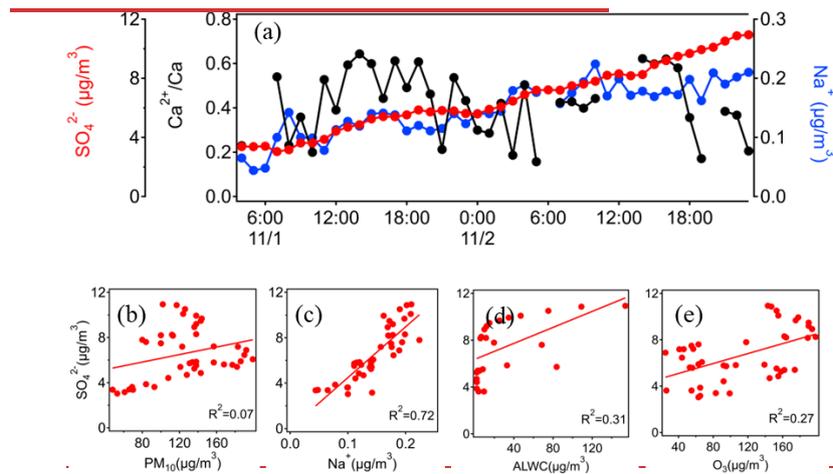

724 Figure 11c investigates the conjoint impact of multiple parameters on the
725 formation of nitrate. In general, NO₃⁻ was more favored under higher NO₂, which was
726 obviously expected as NO₃⁻ could be either formed by the photochemical oxidation of
727 NO₂ by OH radicals at daytime (Hertel et al., 2012) or produced by hydrolysis of N₂O₅
728 from the oxidation of NO₂ by O₃ at nighttime (Ge et al., 2017). In addition, the
729 formation of higher NO₃⁻ was accompanied with higher ALWC and HONO, implying
730 the role of aqueous phase reactions rather than the photochemical reactions. Figure 11e
731 11g separately investigate the relationship between NO₃⁻ and various parameters. NO₃⁻
732 moderately correlated with ALWC (R²=0.38). By relating NO₃⁻ and the multiplication
733 of ALWC and NO₂, the correlation coefficient (R²=0.41) was further improved (Figure
734 11f), indicating the reaction pathway of NO₂ to nitrate in the aqueous phase. Figure 11g
735 also observed strong correlation between NO₃⁻ and HONO (R²=0.57). Alieke et al.
736 (2002) proposed that the heterogeneous reactions of NO₂ on the surface of moist
737 particles produced both nitrate and HONO, i.e.,

739 Compared to the mean ALWC (11.8 ± 17.1 μg/m³) during P2, ALWC during P3
740 was much higher of 29.1 ± 38.0 μg/m³. This was mainly ascribed to the higher
741 atmospheric water vapor during P3, which was evidently caused by the backflows of
742 oceanic air masses. The different levels of ALWC between P2 and P3 caused divergent
743 role of aqueous processing in the secondary aerosol formation.

744 As for sulfate, its temporal variation during P3 was quite different from NO₃⁻ that

745 it showed no diurnal pattern while presented a gradually increasing trend (Figure 12a).
 746 This suggested sulfate had gone through a different formation mechanism from nitrate.
 747 SO_4^{2-} correlated strongly with Na^+ (Figure 12c), which can be regarded as the tracer of
 748 sea salts. The co-variation of SO_4^{2-} and Na^+ probably suggested that a portion of sulfate
 749 was aged and directly transported by the oceanic air masses. Additionally, SO_4^{2-} had
 750 weakly positive correlation with O_3 (Figure 12d) and ALWC (Figure 12e), indicating
 751 that both gas and aqueous phase processes contributed to the secondary formation of
 752 sulfate to some extent. Figure 12a also adds the time-series of Ca^{2+}/Ca , which didn't
 753 co-vary with either sulfate or nitrate. This probably indicated that the chemical reactions
 754 between acidic gaseous precursors and dust mineral components were negligible.

755
 756 Figure 12. (a) Time-series of sulfate, Na^+ , and Ca^{2+}/Ca during P3. Linear
 757 correlation between sulfate and (b) PM_{10} , (c) Na^+ , (d) O_3 , and (e) ALWC.

758
 759 To assess whether dust or sea salts participated in the heterogeneous reactions of
 760 secondary aerosol during P3, the ISORROPIA II model was run with different scenarios.
 761 Figure S1 shows the model performance for SO_4^{2-} , NO_3^- , NH_4^+ , and NH_3 based on the

762 ~~SO₄²⁻-NO₃⁻-NH₄⁺-Cl⁻-NH₃-HCl-HNO₃ system. After adding Ca²⁺ into this~~
763 ~~thermodynamic equilibrium system, the correlations between the simulations vs~~
764 ~~observations for all four species were lowered with different extents (Figure S2). This~~
765 ~~indicated that Ca²⁺ was not internally mixed with sulfate and nitrate and probably~~
766 ~~suggested that the heterogeneous reactions on dust were very limited.~~

767 Then Na⁺ was added into the thermodynamic equilibrium system (Figure S3). It
768 could be seen the model performance was slightly improved. The correlation
769 coefficients of the four species were closer to the unity and the regression slopes were
770 also more parallel to the y=x line. This suggested that sea salts were involved in the
771 formation of secondary inorganic aerosols during the dust backflow. This also explained
772 the strong correlation between SO₄²⁻ and Na⁺ during P3.

773

774 **3.4.3-3.5. Estimation of transported and secondarily formed particles during P3**

775 As discussed in the previous sections, the ~~sources of~~ aerosols observed during P3
776 could ~~originate be derived~~ from both aged aerosols transported via the dust backflows
777 and secondary formation. In this section, we aimed to estimate the contribution of
778 transport and secondary formation to the main aerosol species, respectively, based on
779 the simultaneous measurements at the Pudong site and the Lianyungang site. As
780 discussed in Section 3.4.1, Lianyungang acted as an upstream region ~~of where~~ dust
781 ~~transport~~ drifted away from the mainland. The duration of dust ~~duration~~ observed at
782 Lianyungang was approximately from ~~about~~ 5:00, ~~on~~ October 30 to 16:00, ~~on~~
783 October 31, about 46 hours ahead of the dust invasion observed at Pudong (Figure ~~9S2~~).

784 To assess the extents of transported air pollutants, black carbon (BC) was used as
785 a reference aerosol component. As shown in Figure ~~S4S9~~, one BC pollution episode on

Formatted: Font: (Default) Times New Roman, 小四, Font color: Auto, Pattern: Clear

Formatted: Font: (Default) Times New Roman, 小四, Font color: Auto, Pattern: Clear

786 October 30 at Lianyungang was observed. ~~Correspondingly~~Consistently, another BC
787 pollution episode ~~on November 2 emerged~~ at Pudong ~~on November 2 emerged~~ after
788 about 46 hours. Since the air mass trajectory from Lianyungang to Pudong
789 ~~predominantly traversed~~~~was mostly~~ over the ocean, ~~and considering that and~~BC had
790 ~~has~~ no secondary sources, it ~~could~~~~can~~ be reasonably assumed that the differences of
791 BC ~~concentrations~~ between these two sites ~~was~~~~were~~ ascribed to the removal processes
792 of particles.

Formatted: Font: (Default) Times New Roman, 小四,

Formatted: Font: (Default) Times New Roman, 小四,
Font color: Auto, Pattern: Clear

793 ~~To determine the removal fractions of aerosols during dust transport, we first~~ We
794 ~~further~~ defined the average concentrations of various aerosol components during the
795 ~~preceding previous~~ five hours of the dust at Pudong as their background concentrations.
796 Then, a coefficient k was derived to calculate the removal fractions of aerosols during
797 the dust transport as below.

Formatted: Font: (Default) Times New Roman, 小四,
Font color: Auto, Pattern: Clear

Formatted: Font: (Default) Times New Roman, 小四,
Font color: Auto, Pattern: Clear

$$k = \frac{AV_{LYG,BC} - (AV_{PD,BC} - BKG_{PD,BC})}{AV_{LYG,BC}}$$

801 $AV_{LYG,BC}$ and $AV_{PD,BC}$ represent the average concentration of BC at Lianyungang
802 and Pudong during their respective dust period. $BKG_{PD,BC}$ represents the background
803 concentration of BC at Pudong. ~~By a~~Assuming that other aerosol species were removed
804 ~~at~~~~with~~ a similar efficiency as BC, the amounts of transported aerosol species from
805 Lianyungang to Pudong can be estimated as below.

$$TP_{PD,i} = AV_{LYG,i} \times (1 - k)$$

807 $TP_{PD,i}$ represents the transported amounts ~~for~~~~of~~ aerosol species i . Then, the
808 secondarily formed aerosol species i at Pudong can be calculated as below.

$$SF_{PD,i} = AV_{PD,i} - BKG_{PD,i} - TP_{PD,i}$$

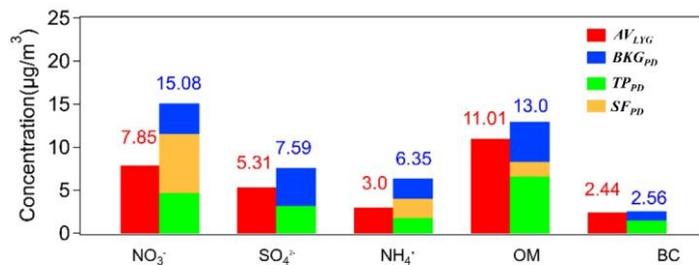

810 Figure ~~13-8~~ shows the results of the transported and the secondarily formed aerosol

811 species during P3. It was calculated that the secondarily formed and transported NO_3^-
 812 averaged $6.8\mu\text{g}/\text{m}^3$ and $4.7\mu\text{g}/\text{m}^3$, accounting for about 45% and 31% of its total mass
 813 concentration, respectively. This was consistent with the earlier analysis ~~above~~ that a
 814 considerable portion of nitrate was formed through the aqueous phase secondary
 815 formation. In contrast, it was calculated that the transported SO_4^{2-} accounted for about
 816 42% of its total mass concentration, while the secondarily formed SO_4^{2-} was almost
 817 negligible. This was also consistent with the phenomenon that SO_4^{2-} correlated
 818 significantly with Na^+ (Figure ~~12e6b~~), ~~suggesting most sulfate was aged and~~
 819 ~~transported~~. As for NH_4^+ , ~~it exhibited a similar apportionment as its origin~~
 820 ~~apportionment was similar to~~ NO_3^- ~~that, with~~ the secondarily formed and transported
 821 NH_4^+ accounted ~~ing~~ for about 35% and 28% of its total mass concentration, respectively.
 822 Compared to NO_3^- and NH_4^+ , OM was more dominated by transport (57%) while its
 823 secondary formation only accounted for about 13%.

 828 P3.

829

830 4. Conclusion

831 During October 29 to November 2, 2019, a long-lasting dust event was observed in
832 Shanghai based on a synergy measurement of near surface air pollutants, aerosol lidar,
833 wind profiling lidar, and air masses trajectory modeling. During the whole dust period,
834 the mean concentrations of PM_{2.5} and PM₁₀ reached $53.3 \pm 20.5 \mu\text{g}/\text{m}^3$ and $172.4 \pm$
835 $70.2 \mu\text{g}/\text{m}^3$. Different from most dust events, this dust event was characterized of
836 exceptionally high relative humidity ($71 \pm 26\%$) and low wind speed ($0.54 \pm 0.59 \text{m/s}$).
837 Due to this stagnant synoptic condition, the mean concentrations of main gaseous
838 pollutants such as O₃, SO₂, and NO₂ reached $86.0 \pm 47.8 \mu\text{g}/\text{m}^3$, $11.8 \pm 3.4 \mu\text{g}/\text{m}^3$, and
839 $63.3 \pm 27.9 \mu\text{g}/\text{m}^3$, respectively, even higher than those during the non-dust period.

840 The dust event was divided into three stages from P1 – P3. P1 was a short dust
841 episode ~~from 4:00–13:00, October 29,~~ when wind profiles showed dominant northwest
842 winds from the ground to the altitudes of around 2km, indicating the presence of a
843 strong synoptic system. P2 was a dust episode ~~from 14:00, October 29 to 3:00,~~
844 ~~November 1,~~ when RH was moderately high of $70 \pm 26\%$ and the southeasterlies
845 prevailed with partial air masses from coastal regions. P3 was a rarely observed dust
846 backflow transport episode ~~from 4:00, November 1 to 23:00, November 2.~~ The air
847 masses originated from the Shandong Peninsula and the northern region of Jiangsu
848 province, and then migrated over the Yellow Sea and the East China Sea. RH reached
849 the highest of $76 \pm 24\%$ among the three stages of the dust event.

850 During P2, mineral aerosols accounted for 33% in PM_{2.5}, the highest among all
851 three stages. Abnormally high O₃ concentrations were observed, much higher than the
852 non-dust days. This was partially due to the weak synoptic system that exerted weak
853 dilution effect on the local air pollutants. ~~Also, part of O₃ could be transported from the~~
854 ~~high ozone oceanic areas.~~ The ozone lidar observed that the subsidence of dust particles

855 probably down drafted high-altitude O₃ and also contributed to the high O₃ near the
856 ground. As a result, sulfate and nitrate moderately correlated with O₃ while had almost
857 no correlation with ALWC, indicating that the formation of secondary aerosols during
858 P2 should be mainly promoted via the gas-phase oxidations.

859 During P3, a special phenomenon of dust backflow was observed and confirmed
860 by various evidences. Two upstream sites (Qingdao and Lianyungang) showed dust
861 occurrences about 48 hours ahead that of Shanghai, consistent with the transport
862 duration of the dust backflow from the Shandong Peninsula to Shanghai over the Yellow
863 Sea and the East China Sea. As a result, the highest Ca²⁺/Ca ratio of 0.38 ± 0.19 was
864 observed during P3, which should be due to that the lingerer of dust plumes over the
865 open ocean facilitated efficient solubility of calcium. ~~In addition~~ Moreover, the mass
866 concentrations contributions of V and Ni significantly increased, indicating the mixing
867 between dust and marine vessel emissions. ~~The highest Ca²⁺/Ca ratio of 0.38 ± 0.19~~
868 ~~was observed during P3, which should be due to that the lingerer of dust plumes over~~
869 ~~the open ocean facilitated efficient solubility of calcium.~~ Different from P2, nitrate
870 ~~didn't correlate with O₃, while it was favored under high NO₂ and significantly~~
871 ~~correlated with ALWC but not with O₃, and strongly correlated with HONO, indicating~~
872 ~~its aqueous-phase the reaction pathway of NO₂ to nitrate in the aqueous phase. As~~
873 ~~for~~ Also, sulfate and nitrate exhibited the moderate to strong correlations with between
874 SO₄²⁻ and Na⁺, suggesting sea salts as a medium for the heterogeneous reactions. ed
875 ~~that a portion of sulfate was aged and directly transported by the oceanic air masses.~~
876 ~~The ISORROPIA II modeling added Na⁺ into the~~
877 SO₄²⁻=NO₃⁻=NH₄⁺=Cl⁻=NH₃=HCl=HNO₃ system and found the models performances
878 ~~of simulating the major aerosol and gaseous species could be improved. As a~~

879 ~~comparison, the models performances became worse after adding Ca^{2+} . This suggested~~
880 ~~that sea salts participated in the secondary aerosol formation while dust heterogeneous~~
881 ~~reactions were limited during P3.~~

882 By analyzing various chemical tracers, the formation extent of SNA was found
883 much stronger during P3 than during P2. Both NH_3 and $\epsilon(\text{NH}_4^+)$
884 $(\text{NH}_4^+/(\text{NH}_3+\text{NH}_4^+))$ determined the concentrations of SNA. To explain the relatively
885 high $\epsilon(\text{NH}_4^+)$ values during P3, the uptake coefficient of NH_3 (γ_{NH_3}) on particles is
886 calculated. γ_{NH_3} negatively varied with the intensity of dust, which were attributed to
887 two factors. Higher contributions of alkali metal components suppressed the
888 neutralization capacity of NH_3 on acids, thereby lowering γ_{NH_3} during P2. Also,
889 relatively high aerosol pH during P2 didn't facilitate the uptake of NH_3 and the
890 subsequent aerosol formation.

Formatted: Left

Formatted: Subscript

891 Based on a simplified method, the amounts of transported and secondarily formed
892 particles during P3 were quantified. It was calculated that about 45% and 31% of NO_3^-
893 was contributed by secondary formation and transport, respectively. In contrast, the
894 transported SO_4^{2-} accounted for about 42% of its total mass concentration while the rest
895 was from its background concentration with negligible secondary formation. OM was
896 dominated by transport (57%) while its secondary formation only accounted for about
897 13%.
