

# Oxidative potential apportionment of atmospheric PM<sub>1</sub>: A new approach combining high-sensitive online analysers for chemical composition and offline OP measurement technique

Authors' response

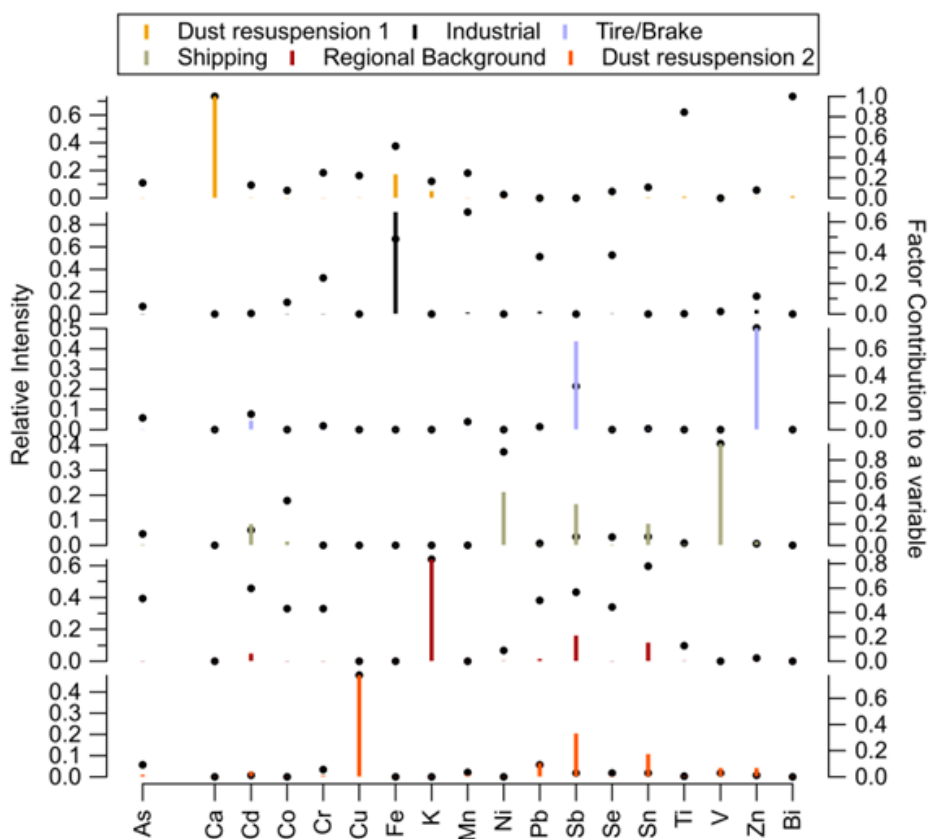

We would like to thank the referees for their time to evaluate our manuscript and for their positive and constructive feedbacks, which helped improve the quality of the paper. Our responses to the comments are presented below (in blue). Orange sentences are directly taken from the corrected manuscript.

**General revisions:** All grammatical and cross-referencing errors in the text were corrected (listed below). Thank you very much to our referees.

- Line 12. Check first sentence of the Abstract  
Response: A part of the sentence had unfortunately been truncated. It has been corrected by the following sentence: « Source apportionment models were widely used to successfully assign highly-time resolved aerosol data to specific emissions and/or atmospheric chemical processes. ».
- Line 15. Check verb person: OP measurement have...  
Response: The sentence was corrected in the manuscript by the following sentence: « OP measurement has [...] ».
- Line 20: use Xact 625i (as in the main text) instead of Xact,  
Response: Corrected.
- Lines 26-27: Sulfate and nitrate formed from SO<sub>2</sub> and NO<sub>x</sub> also originated by combustion processes.  
Response: The sentence has been modified in the manuscript as following: « The results show that besides the high contribution of secondary ammonium sulfate (28%) and organic nitrate (19%), about 50% of PM<sub>1</sub> originated from distinct combustion sources, including emissions from traffic, shipping, industrial activities, cooking, and biomass burning. ».
- Line 29: replaced “is” by “was”  
Response: Corrected.
- Line 62: Chen et al., 2021  
Response: Chen et al., (2021) refers to an OA source apportionment study in Switzerland, whereas Chen et al., (2017) is quoted to support the potential health effects of ambient PM<sub>1</sub>.
- Line 85: replace “AE33 data” by “Aethalometer (AE33) data”  
Response: Corrected.
- Line 87: replace “aethalometer by “AE33”  
Response: Corrected.
- Section 2.1. Please, can you clarify the duration of the sampling period for OP? 7 weeks or 15 days?  
Response: The duration of the sampling period for OP was clarified by the following sentence: « Finally, PM<sub>1</sub> collection for OP analysis was performed for 15 days (from 11<sup>th</sup> July and 25<sup>th</sup> July 2018) every 4 hours on 150 mm diameter quartz fibre filters (Whatman Tissuquartz) pre-heated at 500°C during 8 hours), using a high-volume aerosol sampler (HiVol, Digital DA80) at a flow rate of 30 m<sup>3</sup>.h<sup>-1</sup> ».

- 51 • Line 254; Replace “toxic lead metals” by “toxic lead forms” or “toxic lead compounds”  
52 [Response: Corrected.](#)  
53
- 54 • Line 280; section 2.4.3. Please, provide more information about BC<sub>ff</sub> and BC<sub>wb</sub> estimation  
55 (AAE used...)  
56 [Response: We added the following details to the main text, lines \(287 – 289\): « BC<sub>wb</sub> and BC<sub>ff</sub>](#)  
57 [were deconvolved based on the model of Sandradewi et al., \(2008\). We used the 470 and 950 nm](#)

95 [breeze. ».](#)  
96
- 97 • Line 227: I wonder about the selection of Br for PMF; this element provides little information  
98 as tracer of sources. I would exclude it from the PMF dataset and I would try 6 sources with  
99 XactPMF
- 100 [Response: We agreed with the reviewer that, in general, Br is not attributed to a specific source.](#)  
101 [However, due to its significant variability and concentrations with 99.8% of data points above](#)  
102 [the MDL, we deemed Br to be of interest for performing a PMF. Nevertheless, we tried to](#)

103 increase our solution to 6 factors and excluding the Br element (Figure A1). The new resolved  
 104 factor is interpreted as a split of the dust resuspension factor, dominated by Cu. Despite Cu often  
 105 being associated with brake lining, this factor presented no correlation with traffic tracers (BC<sub>FF</sub>,  
 106 NO<sub>x</sub>, HOA) or any related diurnal patterns. Consequently, this solution did not offer further  
 107 information and was not retained in the study.

110  
 111 **Figure A1-** Average factor profiles from the PMF<sub>metals</sub> solution with Br excluded.

- 112
- 113 • Plot 3b: missing x-axis  
 114 [Response:](#) The x-axis has been added on the Figure 3b.
  - 115
  - 116 • Line 423: missing year of publication of Salameh et al.  
 117 [Response:](#) It has been corrected by: « Salameh et al. 2018 ».
  - 118
  - 119 • Line 474-476. SO<sub>4</sub> also tracer of the shipping profile. This is the second factor explaining  
 120 variation of BC<sub>wb</sub> after the BB.  
 121 [Response:](#) Indeed, we add the following sentences: « This factor further accounts for a  
 122 noticeable variation of sulfate (11.6% of the total sulfate concentration). This is in agreement  
 123 with the results from Chazeau et al., (2021) indicating that during 25% of the days in summer  
 124 2017, sulfate concentrations were prominently influenced by the nearby harbor. ».
  - 125
  - 126 • In the references, 3 publications from Bozzetti et al., are cited. All of them from 2017. In the  
 127 text is not clear which one is referenced and when because they are all identified as Bozzetti et  
 128 al., 2017.

129 [Response:](#) There was a duplicate among the three publications. The two « Bozzetti et al. 2017 »  
130 publications have been differentiated by the addition of (a) and (b).

131

132 • Line 566: missing reference.

133 [Response:](#) The reference “Weber et al. 2021” has been added.

134

---

135 **Response to anonymous referee #1:**

136 Referee comment: The paper is of interest and deserves to be published in ACP although there are some  
137 aspects that can be improved. My main concern is about the application of the PMF to the data set of  
138 metal concentrations before the final PMF-PM1. The results obtained from the PMF metals are not  
139 entirely satisfactory. The diurnal pattern of the tire/brake factor is difficult to explain (despite frequent  
140 spikes). The so-called regional background factor, contains typical brake tracers, such as Cu and Sn,  
141 also Sb. This possible misidentification is reflected in Figure S14 and may affect the analysis of PMF-  
142 PM1. I understand that the PMF-OA can simplify the application of the final PMF-PM1. However, in  
143 my opinion, the prior grouping of the metals into 5 factors decreases the information for the PMF-PM1  
144 and makes interpretation more difficult. Have you tested the PMF-PM1 run using BC sources, OA  
145 sources, ions and metal concentrations? If not, I suggest doing so and comparing the results between the  
146 two approaches.

147 [Response:](#) We agree with the reviewer that the interpretation of the PMF<sub>metals</sub> results needed some  
148 clarifications. It is commonly understood that elements such as Cu, Sb, Sn, and Zn are typically assigned  
149 to brake lining and tire wear emissions. While it has already been pointed out for the coarse (PM<sub>10-2.5</sub>)  
150 and intermediate (PM<sub>2.5-1</sub>) fraction, it is less clear for the fine PM<sub>1</sub> fraction. Visser et al. (2015b)  
151 demonstrated that elements such as Cu, Sn, Sb are mainly found in the coarse mode at the “Marylebone  
152 Road” kerbside site. Hays et al. (2011) described similar trends for a near-highway site, with only Zn  
153 being significantly present in the fine mode. Additionally, these mentioned elements are not found to be  
154 correlated with each other. Such results suggest the existence of significant alternative source for these  
155 elements, potentially mixed here in a regional-scale background factor. Since most trace elements in the  
156 fine mode are non-volatile, they can undergo long-range atmospheric transport (Morawska and Zhang,  
157 2002).

158 This lack of identification was also described by (Visser et al., 2015a), who identified only a mixed  
159 traffic-related factor for the PM1-03 fraction, whereas a brake wear factor was resolved for the PM<sub>2.5-1</sub>  
160 and PM<sub>10-2.5</sub> fraction. In our study, the tire/brake wear factor is mainly constituted of Zn and Sb, which  
161 are among the most represented tracers for these sources in the fine mode. This statement was clarified  
162 into the manuscript (lines 429-433): « Visser et al. (2015b) demonstrated that elements usually assigned  
163 to brake lining and tire wear emissions (e.g. Cu, Sb, Fe or Sn) are mainly found in the coarse mode at  
164 the "Marylebone road" kerbside site, and Hays et al. (2011) reported similar trends for a near-highway  
165 site in Raleigh, with Zn being the only element significantly present in the fine mode. Such results  
166 suggest the existence of significant alternative source for these elements, potentially mixed in the  
167 regional-scale background factor. »

168 [Lines 436-437:](#) « Since most trace elements in the fine mode are non-volatile, they can undergo long-  
169 range atmospheric transport (Morawska and Zhang, 2002). »

170 We also emphasize in the conclusion that incorporating the measurement of additional elements, such  
171 as Ba, S, Cl, and Si, could be an interesting feature to refine some sources. Regarding the PMF  
172 methodology, we followed the reviewer’s recommendation and we performed a PMF-PM1 using BC  
173 sources, OA sources, ions and metals concentrations. We added a dedicated paragraph on the  
174 comparison between the two approaches in the main text as follows (lines 521-533):

175 « To assess the robustness of the PMF<sup>2</sup> solution, the results were compared to a PMF solution utilizing  
176 the OA factors from PMF<sub>organics</sub>, ACSM inorganic species (SO<sub>4</sub><sup>2-</sup>, NO<sub>3</sub><sup>-</sup>, NH<sub>4</sub><sup>+</sup>, Cl<sup>-</sup>), BC sources and  
177 metals concentrations as the input dataset. Consistent with the PMF<sup>2</sup> method, constrains, instrument  
178 weighting, criteria selection and bootstrap analysis were applied and are reported in the Supplement

179 section. This alternative approach successfully identified the same 8 factors (Fig. S18, exhibiting  
 180 comparable mass contributions and very high correlations with the PMF<sup>2</sup> factors time series (Table S5),  
 181 all exceeding a R<sup>2</sup> of 0.9, except for shipping (R<sup>2</sup>=0.81).

182 The biomass burning and shipping factors accounted for slightly higher concentrations in the PMF<sup>2</sup>  
 183 solution, due to slightly elevated contribution of SO<sub>4</sub><sup>2-</sup>, NH<sub>4</sub><sup>+</sup> and MOOA concentrations which dominate  
 184 the PM<sub>1</sub> mass. The metals composition found in the factors from this alternative PMF approach is in  
 185 agreement with the metals profiles from the PMF<sub>metals</sub> solution. Note that Zn and Sb, the most prominent  
 186 elements in the tire/brake metals factor were mainly present in the traffic source. However they  
 187 displayed again some mixing with other factors (dust resuspension, AS-rich and cooking), suggesting  
 188 additional sources unresolved by the current PMF solutions. Previous studies suggested that Zn may  
 189 originate from waste incineration or other industrial processes (Belis et al., 2019; Visser et al., 2015a;  
 190 Manousakas et al., 2022). Comparable results in terms of explained variability were observed,  
 191 emphasizing the suitability of both methods for such study. »

192  
 193 We also provide further details in the supplements, with the Figure A2 (Figure S18 in the main text) and  
 194 Table A1 (Table S5). Lastly, we further discuss the comparison between PMF methodologies in the  
 195 response to reviewer #2.  
 196

197

198  
 199 **Figure A2-** Average factor profiles for the PMF<sub>PM1</sub> solution using OA factors, ACSM inorganic species, BC and  
 200 metals as inputs. The sticks represent the normalized contribution of the variable to the factor (left axis) and  
 201 markers show the normalized factor contribution to each variable (right axis).  
 202

	R <sup>2</sup> with PMF <sup>2</sup> factors	Slope with PMF <sup>2</sup> factors	Relative contribution (%)
Cooking	0.97	1.18	17.4
Biomass Burning	0.93	0.65	3.3
Industrial	0.95	0.95	2.5
Shipping	0.81	0.52	3.6
Traffic	0.96	1.02	21.5
Dust resuspension	0.99	1.07	2.6
ON-rich	1	1.15	23.1
AS-rich	0.99	0.98	26

203

204 **Table A1-** R<sup>2</sup> and slope values for the comparison of the PMF<sub>PM1</sub> (OA factors + metals + ions + BC) factors with PMF<sup>2</sup>  
 205 factors. The relative contributions are also represented (in %).

206

207 **Supplements:**

208 **Preparation of the PMF<sub>PM1</sub> with OA factors + metals + ions + BC dataset:**

209 *Among the 8 identified factors, 4 were not systematically resolved across the several preliminary runs*  
 210 *(cooking, biomass burning, industrial and shipping factors). The solution was constrained using base*  
 211 *case profiles from the 10 factors-solution for industrial, the 11 factors-solution for cooking and*  
 212 *shipping, and the 12 factors-solution for biomass burning. Note that for each run we applied the same*  
 213 *C-values for the instrument weighting than PMF<sup>2</sup> solution. A bootstrap analysis was performed for 100*  
 214 *runs and the accepted runs based on the pre-defined list of criteria (the correlation with base case*  
 215 *profiles for the constrained factors and the monitoring of the dominant variable intensity for the*  
 216 *unconstrained factors) were averaged into a definitive solution.*

217

218 Regarding the factors identified by PMF-PM1, the diurnal cycles identified for the Biomass Burning  
 219 factor are not clear. Furthermore, considering that this source was not identified from the PMF-OA, the  
 220 relatively high contribution obtained for this factor (5% of PM1) in July is surprising. As was done with  
 221 the PMF-metals, it would be useful to perform NWR analysis for the final PMF-PM1 factors.

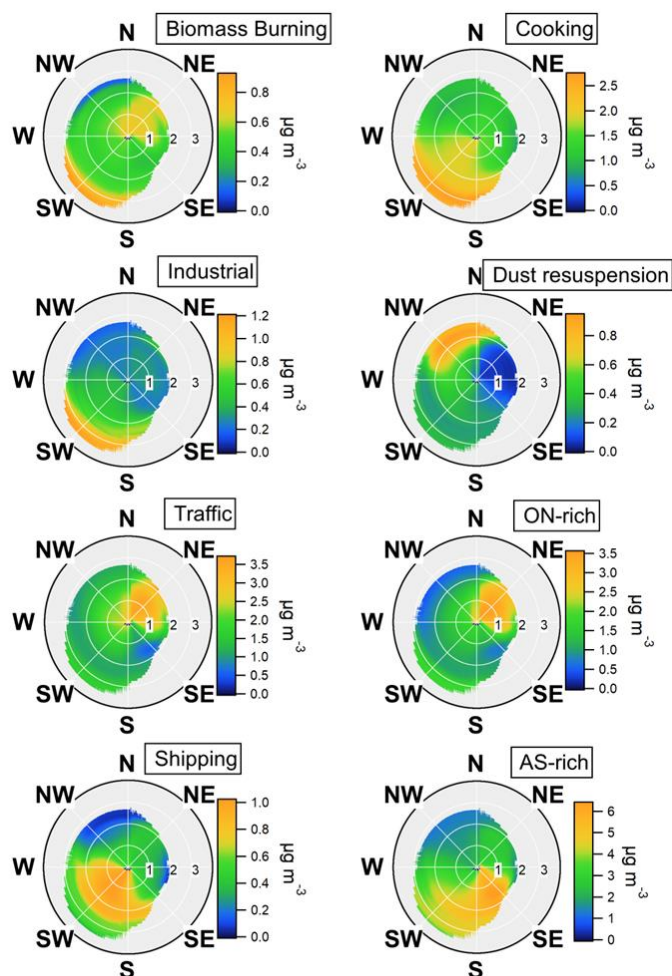

222 **Response:** As mentioned by the reviewer, unfortunately a BBOA was not resolved for the PMF-OA.  
 223 The absence of local domestic heating emissions during this season has made its identification difficult.  
 224 While El Haddad et al. (2013) didn't resolve this factor with the c-ToF-AMS neither, Bozzetti et al.  
 225 (2017) with the offline AMS technic and Salameh et al. (2018) using PM<sub>2.5</sub> offline markers identified a  
 226 low biomass burning contribution in summer, with 5% of the total OA concentration and 2% of the  
 227 PM<sub>2.5</sub> concentrations, respectively. In the current study, the PM<sub>1</sub> biomass burning factor was mainly  
 228 constituted by MOOA (64% of the factor) and to a lesser extent by BC<sub>WB</sub> (19%). Numerous studies  
 229 identified a biomass burning factor for OA that exhibits characteristics of an oxidized OA profile, with  
 230 enhanced signal at m/z 29, m/z 44 (Belis et al., 2019; Bougiatioti et al., 2014). In the PMF-OA, a portion  
 231 of MOOA may account for a secondary biomass burning origin (e.g. wildfire, agricultural activities), as  
 232 the main BBOA fingerprints, m/z 60 and m/z 73 were both predominantly attributed to this factor (40%  
 233 and 39%, respectively).

234 The influence of more secondary process for the biomass burning factor was stated lines 463–467 in the  
 235 manuscript:

236 « While no primary biomass burning organic aerosol (BBOA) factor was resolved with the PMForganics  
 237 analysis in summer, the presence of a significant MOOA contribution reflects the influence of secondary  
 238 process in this biomass burning factor. The low concentration of this factor is in agreement with minor  
 239 regional emissions linked to agricultural activities, wildfires and cooking practices such as BBQ,  
 240 transformed through oxidation processes during regional transport and aging (Chazeau et al., 2022;  
 241 Cubison et al., 2011) ».

242 Moreover, we followed the reviewer's suggestion and the NWR analyses for the PMF-PM<sub>1</sub> factors are displayed in Figure A3 (Figure S17 in the main text). The following lines were modified accordingly:  
 243  
 244 -lines 458 – 460 : « The full PM<sub>1</sub> source apportionment solution is explored in this section with the  
 245 average factor profiles (Fig. 5a), the time series (Fig. 5b), the pie chart of mass contributions (Fig. 5c),  
 246 the average diurnal profiles (Fig. 5d) and the NWR analyses (Fig. S17). »  
 247 -lines 467 – 470 : « The NWR analysis in Fig. S17 showed biomass burning concentrations associated  
 248 with higher wind speed than sources with a local origin (traffic, shipping, cooking and ON-rich),  
 249 corresponding to south-westerly winds from the Mediterranean Sea. Additionally, the north-east land  
 250 breeze advected these aged emissions back to the sampling site. »  
 251 -line 505 : « [...] This factor displayed an origin from the North to East within the land. »  
 252 -line 519 : « [...] This interpretation is supported by the NWR analysis presented in Fig. S17. »  
 253  
 254  
 255

256  
 257 **Figure A3-** NWR plots for each factor of the PMF<sub>PM1</sub> analysis.  
 258

259 Finally, I think the conclusions section could be improved. The discussion can be extended on the  
 260 advantages/disadvantages of the proposed method and the comparison with previous PMF analyzes  
 261 carried out in the area.

262 Response: We thank the reviewer for the suggestion. We added the following discussion to the  
 263 conclusions in lines 666-674: « The PMF<sup>2</sup> approach successfully identified 8 well-resolved sources (AS-  
 264 rich, traffic, ON-rich, cooking, shipping, biomass burning, industrial and dust resuspension), a solution  
 265 not achievable through single PMFs conducted separately on OA and metals datasets. The method

266 enabled the assignment of OA factors, which typically described components arising from a mixture of  
267 sources and chemical processes rather than a single emission source, to more specific PM<sub>1</sub> sources.  
268 Additionally, this approach allowed to assess both the primary and secondary origin of anthropogenic  
269 sources, such as traffic and cooking. However, a limitation of this method is that non-explained  
270 variability and uncertainties of the factors from the first step PMFs will propagate into the PMF<sup>2</sup> results  
271 and therefore need to be carefully assess. The inclusion of additional elements measurements, such as  
272 Ba, S, Cl, and Si to the PMF<sub>metals</sub>, could be an interesting feature to refine some sources and address this  
273 limitation. »

274 [A comparison with previous PMF analyzes carried out in the area was also detailed in the section 3.2.3](#)  
275 [\(lines 534-541\):](#) « In overall, the present PMF approach successfully identified various sources of PM1  
276 during the summer season, consistent with previous studies in Marseille. These sources include traffic  
277 (El Haddad et al., 2013; Bozzetti et al., 2017a; Salameh et al., 2018), cooking (Bozzetti et al., 2017a),  
278 and a minor contribution from biomass burning (Bozzetti et al., 2017a; Salameh et al., 2018). However,  
279 this study marks the first identification of an ON-rich factor. Previous source apportionment of PM<sub>2.5</sub>  
280 markers by Salameh et al. (2018) highlighted the dominant contribution of ammonium sulfate in summer  
281 (35%) and identified a dust factor with a metal composition similar to the current study (Cu, Fe, Ca).  
282 While they identified a fossil fuel factor attributed to mixed harbor and industrial emissions, our results  
283 provide new insights by distinctly separating industrial and shipping emissions simultaneously advected  
284 onsite by sea breeze. ».

286

287

---

288 **Response to anonymous referee #2:**

289 **Referee comment:**

- 290
- 291 • Line 453-454: the sentence stating that the industrial contribution to PM1 found in Marseille is  
292 comparable to the contribution observed in other cities might lead to misleading conclusions.  
293 The industrial contribution being similar and low in different cities could be merely casual or  
294 due to the distance of the sampling stations from the emission spots, and on type of the industrial  
295 processes involved. I think this similar and low industrial contribution to PM1 among different  
296 cities only demonstrates that the urban background stations are typically scarcely affected by  
industrial emissions because of their geographical location.

297 [Response:](#) This statement, as written, is indeed unclear and prone to misinterpretation, thanks for  
298 noticing it. We agreed the distance between the industrial area and the urban site may account for the  
299 observed very low concentrations in comparison to more local sources. However, it is important to note  
300 that industrial plumes are transported by sea breeze conditions, which prevail almost daily in the  
301 Marseille area during the summer.

302 The low PM<sub>1</sub> mass concentration for this source is expected as the size of the industrial particles  
303 generally belongs to the ultrafine mode (<100nm) (Riffault et al., 2015). Chazeau et al. (2021) and El  
304 Haddad et al. (2013) already described that plumes originated from the main industrial area of Fos-Berre  
305 are mainly attributed to ultrafine particles and thus influence the mass only to a minor extent. This  
306 clarification is now articulated in the main text as follows, lines 478-483: « The factor contributes little  
307 to the PM<sub>1</sub> composition (3.2%), which is expected as the size of the industrial particles generally belong  
308 to the ultrafine mode (<100nm) (Riffault et al., 2015). Chazeau et al., (2021) and El Haddad et al., (2013)  
309 already described that plumes originated from the main industrial area of Fos-Berre are advected onsite  
310 by sea breeze conditions and are mainly attributed to ultrafine particles, influencing the mass  
311 concentrations only to a minor extent. Similar contributions were found in another Mediterranean coastal  
312 city, Barcelona (4%; Via et al. (2023)), and in some French urban sites in the vicinity of an industrial  
313 area (Weber et al. 2019). ».

314 • Regarding the interpretation of the OP results:

315 The  $OP_{AA}$  and  $OP_{DTT}$  time series displayed in figure 3a and 6a seems to show a weak correlation. This  
316 is also reflected by the OP multilinear regression results displayed in figure 7 and table 1, where some  
317 PMF factors e.g. dust resuspension and industrial emissions are positively correlated with  $OP_{AA}$  and  
318 negatively correlated or not correlated with  $OP_{DTT}$ . Vice-versa the shipping emission factor and the AS-  
319 rich factor are positively correlated with  $OP_{DTT}$  and negatively correlated or not correlated with  $OP_{AA}$ . I  
320 would discuss more in depth the differences of the results obtained from  $OP_{AA}$  and  $OP_{DTT}$ . What's the  
321 physiological representativeness of  $OP_{AA}$  and  $OP_{DTT}$ ? Which one is more relevant for human health?  
322 Both DTT and AA are reductant substances. It seems that AA is more sensitive to Cu and other elemental  
323 impurities, while DTT is sensitive to other oxidative species, therefore it seems that  $OP_{DTT}$  and  $OP_{AA}$  are  
324 related to different oxidative pathways. Could you briefly elaborate on the physiological  
325 representativeness of these two pathways and which one is more relevant and the specific relevance of  
326 each one? Do  $OP_{AA}$  and  $OP_{DTT}$  provide complementary information or one is more representative than  
327 the other of the real oxidation processes occurring in-vivo? If  $OP_{DTT}$  and  $OP_{AA}$  provide complementary  
328 information, do the authors suggest to always perform both the analyses?

329 Response: Thank you for the feedback, which has enabled us to provide further details on the  
330 interpretation of the OP results and add a section “3.3.4. Discussion” to the manuscript. Indeed, the  
331 association between  $OP^{AA}$  and  $OP^{DTT}$  is moderate to weak ( $r_s = 0.41$ ;  $p < 0.001$ ) and illustrates the  
332 different sensitivity of the two OP tests to chemical constituents found in ambient air. As shown in the  
333 Figure 7, the contribution of the PM sources to OP is dependent on the OP test used. This reflects the  
334 different oxidation pathways involved in the oxidation of the two probes (AA and DTT). A detailed  
335 answer for the physiological representativeness of  $OP_{AA}$  and  $OP_{DTT}$  has been added in the manuscript,  
336 in the section “3.3.4 Discussion”, lines (630 – 637):

337 “AA is naturally present in the lungs, and its predominant anionic form in solution ( $HA^-$ ) is oxidised by  
338 various mechanisms facilitated by  $OH^\bullet$ ,  $O_2^\bullet$ ,  $HO_2^\bullet$  and other radicals, and by transitions metals as Cu (II)  
339 or Fe (III) (Campbell et al., 2019). DTT has a disulfide bond and is considered as a chemical substitute  
340 for cellular reducing agents such as nicotinamide adenine dinucleotide phosphate oxidase (NADPH) or  
341 protein thiols (Verma et al., 2015; Borlaza et al., 2018). Protein thiols play an important role in major  
342 oxidative stress, restoring the redox balance by eliminating free radicals (Baba and Bhatnagar, 2018).  
343 Many studies have linked these two probes (AA and DTT) to transition metals (Cu, Fe, Mn, Zn), EC  
344 and OC (Gao et al., 2020). In addition, the different sensitivity of AA and DTT to both organic  
345 compounds and transition metals has been evidenced in Calas et al., 2018, Gao et al., 2020 and  
346 Pietrogrande et al., (2022).

347 Although no consensus has been reached on an OP test that is more representative of health impact,  
348 epidemiological studies have mainly associated  $OP^{DTT}$  with health endpoints, which has not been  
349 demonstrated with  $OP^{AA}$ . The community currently recommends the complementary use of these two  
350 tests. A detailed response has been added in the manuscript, in the section “3.3.4 Discussion”, lines  
351 (638 – 648):

352 “Today, no consensus has yet been reached on which OP test is most representative of health impact,  
353 and the community still recommends the complementary use of OP tests, in particular the association of  
354 both AA and thiol-based (DTT or GSH) assays (Moufarrej et al., 2020). This association is today the  
355 unique way of assessing the full panel of the most oxidising compounds of PM. However, recent studies  
356 have shown positive associations between  $OP^{DTT}$  and various acute cardiac (myocardial infarction) and  
357 respiratory endpoints, supporting the interest of the  $OP^{DTT}$  assay for this purpose (Abrams et al., 2017;  
358 Weichenthal et al., 2016; He and Zhang, 2023). On the contrary, several studies did not associate  $OP^{AA}$   
359 to health endpoints including early-life outcomes, respiratory and cardiovascular mortality,  
360 cardiorespiratory emergencies and lung cancer mortality (Borlaza et al., 2023; Marsal et al., 2023).  
361 Nonetheless, a recent study has associated  $OP^{AA}$  with oxidative damage to DNA (Marsal et al., 2023).  
362 These results so far may suggest that  $OP^{AA}$  provides partial information on the link between OP and  
363 adverse health effects, and further epidemiological studies are needed to determine whether  $OP^{AA}$  should  
364 be considered as a proxy for health impact.”

365 Moreover, from the results displayed in figure 7, where the sources are ranked by their contribution to  
366  $OP_{DTT}$ ,  $OP_{AA}$  and  $PM_1$ , it seems that there's a certain correlation between the sources contributions to  
367  $PM_1$  and  $OP_{DTT}$ . On the opposite, such a correlation is completely missing between sources contribution  
368 to  $OP_{AA}$  and  $PM_1$  mass. Does it suggest that AA is more sensitive to the chemical composition of the  
369 sources, while DTT is more sensitive to the aerosol concentration, and therefore less representative of  
370 the real oxidative potential of an aerosol source? Without a critical discussion on these aspects, the  
371 results displayed in figure 7 might lead to contradictory conclusions, for example the industrial factor  
372 can be considered as toxic or non toxic if looking respectively at  $OP_{AA}$  or  $OP_{DTT}$  results.

373 **Response:** Thank you for your pertinent comment. Indeed, as in many other studies referenced in section  
374 “3.1 “OP results” lines (371-372),  $PM_1$  is more associated with  $OP^{DTT}$  than with  $OP^{AA}$  ( $r_s PM_1$  vs  $OP_v^{AA}$   
375 = 0.23 ( $p < 0.01$ ) and  $r_s PM_1$  vs  $OP_v^{DTT}$  = 0.63 ( $p < 0.001$ )). Associations values were mentioned in the  
376 manuscript in lines (366-367), but these values have not been discussed in depth. These values reflected  
377 the sensitivity of DTT to a wider range of chemical compounds, implying a stronger association with  
378 aerosol concentration, whereas AA displays a heightened sensitivity to chemical composition (which  
379 exhibit robust specificity). Indeed,  $OP_v^{AA}$  is known to be more sensitive to some PM components as  
380 Cu(II) or Fe(II) but also some quinones (Calas et al., 2019, Campbell et al., 2019; Pietrogrande et al.,  
381 2022). In addition, the state-of-the-art highlighted PM concentration as a significant predictor of  $OP_v^{DTT}$   
382 in univariate models (Janssen et al., 2014; Weber et al., 2018). For the moment, we need to keep a  
383 critical eye on the results since a multitude of sources have been identified by the two OP tests and  
384 therefore deserve to be considered. A detailed response explaining the observed correlation coefficients  
385 has been added in the manuscript, section 3.1 “OP results”, lines (366 – 373):

386 “Spearman coefficients ( $r_s$ ) between  $PM_1$  mass measured by FIDAS and OP display some differences ( $r_s$   
387  $PM_1$  vs  $OP_v^{AA}$  = 0.23 ( $p < 0.01$ ) and  $r_s PM_1$  vs  $OP_v^{DTT}$  = 0.63 ( $p < 0.001$ )) where  $PM_1$  is much more  
388 associated to  $OP_v^{DTT}$  than to  $OP_v^{AA}$ . These Spearman coefficients are close to those found by in 't Veld  
389 et al., (2023) on  $PM_1$  all year long in a similar urban coastal environment (Barcelona). The higher  
390 association between  $OP_v^{DTT}$  and  $PM_1$  compared to  $OP_v^{AA}$  and  $PM_1$  has already been observed in other  
391 studies conducted on  $PM_{10}$  (Calas et al., 2019; Weber et al., 2021; Janssen et al., 2014). This phenomenon  
392 is attributed to AA's heightened sensitivity to chemical composition, exhibiting robust specificity.  
393 Moreover, DTT demonstrates superior sensitivity to aerosol concentration owing to its more balanced  
394 sensitivities to chemical constituents (Gao et al., 2020).”

395 • Regarding the source apportionment strategy:

396 I suggest the authors to justify the adoption of the PMF<sup>2</sup> approach. This approach utilized the outputs of  
397 the OA and metals source apportionments as input for a comprehensive  $PM_1$  source apportionment.  
398 Alternatively, a unique PMF analysis could have been performed using the ACSM and Xact raw data  
399 as direct inputs for the  $PM_1$  source apportionment. The PMF<sup>2</sup> approach has two drawbacks. Firstly, the  
400 uncertainties of the first PMF analyses and their unexplained variability are propagated into the  
401  $PM_1$  source apportionment. Secondly, the OA and metal aerosol sources, which had been already  
402 resolved by the first PMFs (on ACSM and Xact data), are then reapportioned and potentially re-mixed  
403 into different  $PM_1$  factors. This is observed in figure 5a for the traffic and cooking factors, where a non-  
404 negligible contribution from LOOA and MOOA is observed. Similarly, the brake/tire factor resolved by  
405 the metals' PMF, is splitted into 4  $PM_1$  factors (traffic, AS-rich, industrial, and biomass burning). This  
406 suggests that either the  $PM_1$  source apportionment hasn't been fully-optimized, or the input factor time  
407 series were already not well resolved from other sources, and therefore the error of the OA and metal  
408 PMFs have been propagated into the final  $PM_1$  source apportionment. Instead, using the OA ACSM raw  
409 data as input for the  $PM_1$  source apportionment might help resolving a better traffic profile, because the  
410 OA ACSM mass spectra contain many hydrocarbon fragments which are typically related to traffic  
411 exhaust.

412 **Response:** We thank referee #2 for the insightful comments. One of the objectives of the current study  
413 was to assess the PM sources contributions to OP through three scenarios: first, an OP apportionment  
414 using only OA factors from the PMF<sub>organics</sub>; second, an OP apportionment using only metals factors from  
415 the PMF<sub>metals</sub>; and third, to follow an harmonized methodology, we explored the third scenario (OP

416 apportionment using PM<sub>1</sub> factors) by combining together the factors from both PMF<sub>organics</sub> and PMF<sub>metals</sub>  
417 as inputs for the PMF<sub>PM1</sub>. The PMF<sup>2</sup> approach was the most suitable method for this purpose,  
418 emphasizing the importance of considering all PM<sub>1</sub> fractions to apportion OP.

419 Moreover, using OA PMF factors as inputs allows to quantify the primary/secondary OA contribution  
420 to the PM<sub>1</sub> sources. A limitation of performing PMF on OA mass spectra from ACSM/AMS is the  
421 resolution of the SOA origin. SOA factors are usually reported as either a single factor or two factors  
422 separated by their degree of oxygenation (LOOA/MOOA) rather than in terms of sources. The PMF<sup>2</sup>  
423 approach enables a more accurate identification of SOA sources, addressing this limitation. Given that  
424 several studies highlighted the role of SOA in oxidative potential, it is important to include an accurate  
425 quantification of this fraction in the PM<sub>1</sub> sources, a step not achievable using the raw OA mass spectra.  
426 We added to the Introduction section the justification of using PMF<sup>2</sup> method (lines 87-92): « A known  
427 drawback of performing PMF on OA mass spectra from ACSM/AMS is the resolution of the secondary  
428 organic aerosol (SOA) origin. SOA factors are usually reported as either a single factor or two factors  
429 separated by their degree of oxygenation rather than in terms of sources. A PMF<sup>2</sup> approach using  
430 previous OA factors combined with other species and/or PMF factors may enable a more accurate  
431 identification and quantification of the SOA fraction in the PM sources. The current study addresses this  
432 challenge by intending the PMF<sup>2</sup> method for the PM<sub>1</sub> fraction measured with online analysers (i.e. ToF-  
433 ACSM, Xact 625i and AE33) at high time resolution (<1h). »

434 We fully agree with the reviewer about the first drawback. Since we performed bootstraps for the two  
435 first PMFs we were able to statistically estimate uncertainties of the factors. These uncertainties are  
436 incorporated in the error inputs for the PMF<sub>PM1</sub> analysis. It is true also that the non-explained variability  
437 of the first PMFs is propagated into the PM<sub>1</sub> source apportionment, representing a notable inconvenience  
438 of a multi-step PMF approach. This is now explicitly stated as a limit of the methodology in the  
439 conclusion (lines 671-673): « However, a limitation of this method is that non-explained variability and  
440 uncertainties of the factors from the first step PMFs will propagate into the PMF<sup>2</sup> results and therefore  
441 need to be carefully assessed. »

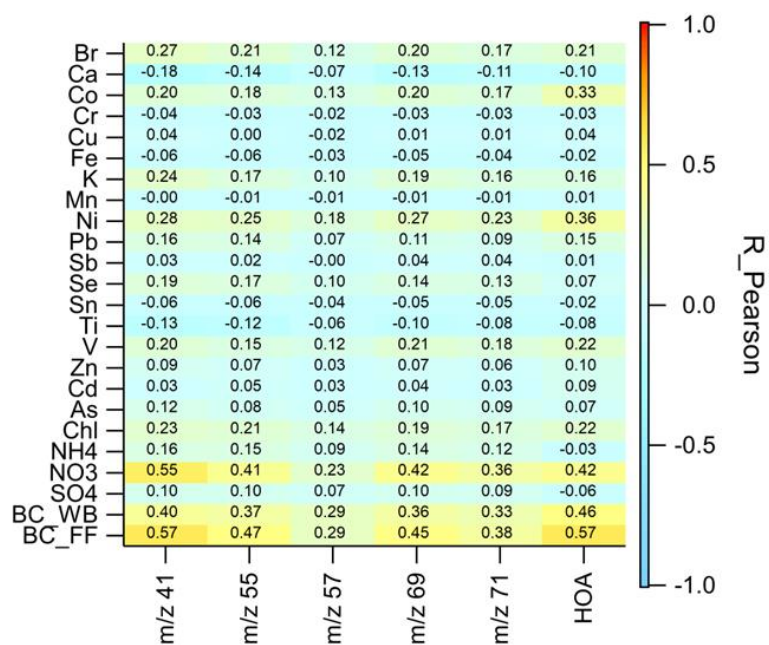

442 HOA and COA were constrained in the PMF<sub>organics</sub> using reference profiles accounting for primary traffic  
443 and cooking emissions in an urban environment. Therefore, the contribution of the fast oxidation of  
444 freshly emitted primary OA is expected to be included in the SOA factors, as demonstrated in Chazeau  
445 et al. (2022). This explains why some LOOA and MOOA fractions are attributed to the traffic and  
446 cooking sources. The SOA contribution to the traffic source was previously mentioned lines 491-493:  
447 « It should be emphasized that 23% of the traffic source was constituted of SOA (LOOA and MOOA)  
448 meaning that primary traffic contribution is mixed with secondary aerosol concentrations attributed to  
449 fast oxidation of freshly emitted particles (Chirico et al., 2011). ».

450 The tire/brake factor displayed the highest unexplained variation, probably due to some mixing with  
451 other sources as suggested by the reviewer. It was previously noted in lines 490-491 and is now further  
452 discussed in the new paragraph comparing the two PMF<sup>2</sup> approach.

453 We agree with the reviewer that including OA raw data as PMF inputs is a very interesting method to  
454 explore the PM<sub>1</sub> sources as it was already performed by Belis et al. (2019). There are many possibilities  
455 in combining datasets, whether in their raw format or as PMF factors, that would need further  
456 investigation to establish a more standardized protocol for PM<sub>1</sub> source apportionment. Despite this  
457 statement, the scope of the present manuscript is not to inter-compare alternative PMF methodologies,  
458 which could be the focus of a fully dedicated paper.

459 However, we inspected correlations between some hydrocarbon OA fragments related to traffic exhaust  
460 and the other PM<sub>1</sub> compounds (metals, BC, SO<sub>4</sub>, NO<sub>3</sub>, NH<sub>4</sub> and Cl) in Figure A4. The results did not  
461 show any better correlation than comparing with the HOA factor. For these reasons, we do not think it  
462 would be appropriate to present results from a PMF analysis based on OA fragments + inorganic  
463 compounds.

464 Nevertheless, we performed PMF on OA factors and metals, as suggested by the referee #1, and  
465 compared it to the PMF<sup>2</sup> approach to support our assessment. The results were relatively similar and are  
466 detailed in lines 521- 533 in the section 3.2.3.

467

468 **Figure A4** – R Pearson correlation matrix between metals, BC, ACSM inorganic species and OA hydrocarbon  
 469 fragments typically related to traffic exhaust.
