**Abstract.** In recent years research on positive social tipping dynamics in response to the climate crisis has produced invaluable insights. In contrast, relatively little attention has been given to the potentially negative social tipping processes that might unfold due to an increasingly destabilised Earth system, and how they might in turn reinforce social and ecological destabilisation dynamics and/or impede positive social change. In this paper, we discuss selected potential negative social tipping processes (anomie, radicalisation and polarisation, displacement, conflict and financial destabilisation), linked to Earth system destabilisation. We draw on related research to understand the drivers and likelihood of these negative tipping dynamics, their potential effects on human societies and the Earth system, and the potential for cascading interactions (e.g. food insecurity and displacement), contributing to systemic risks. This first attempt to provide an explorative conceptualisation and empirical account of potential negative social tipping dynamics linked to Earth system destabilisation is intended to motivate further research into an under-studied area that is nonetheless crucial for our ability to respond to the climate crisis and for ensuring that positive social tipping dynamics are not averted by negative ones.

## 1 Introduction

Recent advances in research on Earth system tipping points (ESTPs) (e.g. Armstrong McKay et al., 2022), paint an increasingly alarming picture of the state of our planetary system. Understanding tipping points and other forms of non-linear change is now widely recognised as critical to managing and responding to change in complex systems (Scheffer, 2009). We define social tipping points on the basis of mathematics of dynamical systems (Strogatz, 2000). Specifically, tipping points in dynamical social systems are critical thresholds where a small change in a variable describing the state of the social system or

48 in a parameter capturing external influences leads to an often abrupt qualitative change of the dynamical social system, i.e. the  
49 social dynamical system undergoes a phase transition from one state to another (Winkelmann et al 2022). Tipping occurs  
50 because positive feedback mechanisms create self-reinforcing loops, where the small change in one component of the system  
51 triggers changes that further reinforce the initial change. Tipping is further enabled by weak negative feedback mechanisms  
52 that tend to stabilise a dynamical system. Tipping is usually difficult to reverse due to hysteresis that locks the system within  
53 the new state or within the trajectory to a new state, even if the original drivers for the change are removed (Wiedermann et  
54 al., 2020, Winkelmann et al., 2022). Normatively speaking, social tipping points can be both positive (predominantly beneficial  
55 to humans and the natural systems) or negative if they result in catastrophic consequences for human societies and ecological  
56 systems (IPCC, 2022; Lenton et al., 2023).

57 Increasing attention is also being paid to cascade effects that connect different systems, implying that a change in one system  
58 may trigger further change in another system (Liu et al., 2023). Here, we consider a tipping cascade to take place when one  
59 tipping point triggers the crossing of another tipping point (Klose et al., 2021). We focus here moreover on negative social  
60 tipping processes that have the potential to feedback to the Earth system, further destabilising it, i.e. we are interested in  
61 processes where the Earth system destabilisation contributes to social system destabilisation, which then further destabilises  
62 the Earth system (e.g. due to lack of cooperation), creating a potential feedback loop. We note that this paper is focusing on  
63 climate ESTPs, but the same rationale can be broadly generalised to other Earth systems.

64 Although research on the potential for positive social tipping dynamics in various systems (e.g., food, energy, transportation,  
65 financial, behavioural etc.) has started to emerge (Tàbara et al., 2018; Otto et al., 2020; Lenton 2020; Lenton et al., 2022;  
66 Winkelmann et al., 2022; Milkoreit, 2023), there has been limited research on negative social tipping dynamics that might be  
67 triggered by climate change (Laybourn et al., 2023). This is noteworthy, not least because early research on tipping points in  
68 the social sciences was mostly concerned with undesirable social processes, such as rapid and non-linear patterns of urban  
69 racial segregation in the United States (Schelling, 1978). More recently, researchers have used dynamical systems analyses to  
70 empirically study tipping points in school segregation (Spaiser et al., 2018), political instability of countries (Grimm &  
71 Schneider, 2011), and rapid proliferation of misinformation (Törnberg, 2018).

72 We argue that studying negative social tipping points in the context of Earth system destabilisation is important because it  
73 highlights the risks generated by overshooting temperature thresholds such as 1.5°C. While indeed every tenth of a degree  
74 matters, framing around climate policy is moving in the direction of making overshoot socially acceptable. Overshoots are  
75 presented as temporary, with the deployment of carbon dioxide removal (CDR) being able to recover temperatures back into  
76 the ‘safe zone’ by the end of the century. The risks of ESTPs however makes overshooting very dangerous, as overshooting  
77 may trigger ESTPs, which then cannot be reversed even if we return to lower global warming after the overshoot period.  
78 Triggering ESTPs on the other hand poses the risk of escalating climate change impacts. Moreover, overshooting would lead  
79 to further ecological destabilisation, which might be reversible in terms of returning to lower global warming, but in the  
80 meanwhile the ecological destabilisation could trigger negative social tipping points described here and these negative social  
81 tipping points could feedback to the Earth system, further destabilising it, potentially leading to ESTPs being triggered. We  
82 believe that understanding these potential complex interactions is important, because humans have agency and can make  
83 decisions trying to prevent such escalating processes. None of the scenarios described here are inevitable and although many  
84 dynamics are already unfolding today, we have not reached a point of no return.

85 Negative and potentially catastrophic consequences are unequally distributed both internationally, as well as within each  
86 society. Research has emphasised that low-income countries that have often contributed least to the destabilisation of the Earth  
87 system, will bear the brunt of the climate change impacts (IPCC, 2022; Lenton et al., 2023). Moreover, within each society, it

88 is the most vulnerable groups, such as children (Thiery et al., 2021; UNICEF, 2021), women (Denton, 2002), minority groups  
89 (Berberian et al., 2022, Donaghy et al., 2023) and generally the less affluent (Thomas et al., 2019), who will be most affected  
90 by climate change impacts. Triggering negative social tipping points will have considerable consequences for these vulnerable  
91 groups, further amplifying their vulnerability and stressing the need for climate justice (Newell et al., 2021).

92 In this perspective, we pose the following questions: (1) What are the potential negative social tipping points that the  
93 destabilisation of the Earth system could trigger? (2) To what extent could the triggering of negative social tipping points  
94 further destabilise the Earth system? (3) How do these negative tipping elements interact and what cascades could these  
95 interactions cause? (4) What research and modelling approaches are suitable to studying negative social tipping points and  
96 cascades? And (5) what intervention options are available to prevent negative social tipping points and cascades?

## 97 **2 Mapping out Negative Social Tipping**

98 We identify five negative social tipping processes that according to some existing evidence could be triggered by Earth system  
99 destabilisation (see Figure 1). The part or subsystem of a larger system that can pass a tipping point is referred to as the tipping  
100 element. Drawing on the positive social tipping element framework developed by Otto et al. (2020), we identify four social  
101 tipping elements (TE) that have the potential for negative tipping processes (TP): socio-psychological systems (TE1), political  
102 systems (TE2), human settlements (TE3) and financial markets (TE4). Figure 1 provides an overview of these tipping elements  
103 and the tipping that could be triggered within these tipping elements: Anomie (TP1.1), Radicalisation & Polarisation  
104 (TP1.2), Displacement (TP2.1), Conflict (TP3.1) and Financial Destabilisation (TP4.1). All these processes can unfold across  
105 different levels of social structure on different time- and spatial scales. Specifically, tipping in all tipping elements can occur  
106 as rapidly as hours, triggered by a major shock event or unfold more slowly (years) over cascading pathways as the effects of  
107 ESTPs accumulate. Tipping can also occur only locally, affecting a specific community or spread across a nation or the globe.  
108 The figure also indicates the potential for interactions between various negative tipping elements. The interactions between  
109 different TEs indicate different possible destabilisation pathways that could lead to the crossing of negative tipping points  
110 across scales. This illustrative selection is based on evidence for tipping processes in these subsystems and evidence that Earth  
111 system destabilisation has a direct effect on these subsystems.

112 [FIGURE 1 HERE]

### 113 **2.1 Anomie**

114 The concept of anomie, which was introduced by Durkheim (1893, 1897) to describe the breakdown of norms and social order  
115 and its relationship to suicide patterns in societies, has evolved over decades of social research (Abrutyn, 2019; Twyman-  
116 Ghoshal, 2021). We define anomie as a state of a society or community that is characterised by a breakdown of social norms,  
117 social trust, social ties, and social reality, resulting in social disorder and disorganisation, disorientation, and disconnection.  
118 These syndromes manifest on the individual level through mental health deterioration, increased suicide rates, and/or increased  
119 deviant behaviour (Brown, 2022; Teymoori et al., 2017). Although this is a relatively new area of research, there is increasing  
120 evidence to suggest that changes in the Earth system can contribute to anomie. For instance, anomie has been observed in the  
121 aftermath of natural disasters, made more likely by climate change (Miller, 2016) and it has been suggested that Earth system  
122 destabilisation may result in a new form of anomie, called environmental anomie (Brown, 2022), where sudden changes to the  
123 physical landscape can upend the established social order and undermine people's ability to comprehend, relate to, and function  
124 within their environment. People from Paradise (California, US), who survived the devastating Camp Fire in 2018 for instance  
125 reported how the wildfire event undermined their ability to comprehend the world around them, because their familiar  
126 environment became unintelligible (e.g. determine wind direction), they were no longer able to relate to and function within

127 their environment. This resulted in a breakdown of self-efficacy, with a sense of unreality taking hold (e.g. burning tree  
128 branches falling from the sky). This experience of environmental anomie was further exacerbated when the affected individuals  
129 witnessed that traditional authorities were overwhelmed and unable to respond to the physical chaos, which undermined  
130 confidence and led to an individuation of suffering and feelings of social isolation, i.e. experience of general anomie. With the  
131 breakdown of social order people were forced to fend for themselves and rules (e.g. regulating traffic) were no longer observed  
132 (Brown, 2022).

133 Beyond anomie resulting from extreme weather events caused by escalating climate change, there is also evidence for a rise  
134 in anomic experiences, particularly by young people and children around the world, contributing to a mental health crisis. In  
135 a first comprehensive study, surveying 10,000 children and young people (aged 16-25 years) in 10 countries (Australia, Brazil,  
136 Finland, France, India, Nigeria, Philippines, Portugal, UK and USA) Hickman et al. (2021) found that more than 45% said  
137 their feelings about climate change negatively affected their daily life and functioning, 75% reported that they find the future  
138 frightening, and 83% said they think people (adults) have failed to take care of the planet. But it is not just the young  
139 experiencing the effects of climate change on mental health – it is negatively affecting the mental health and emotional  
140 wellbeing of people of all ages globally, but more profoundly of poor and vulnerable populations (Lawrence et al., 2021;  
141 Clayton et al., 2017), as well as women and Indigenous people (IPCC, 2022; Sultana, 2022). For a summary of other studies,  
142 see Figure 2.

143 [FIGURE 2 HERE]

144 The extent of tipping dynamics in anomie have not yet been studied directly, but some studies have demonstrated tipping  
145 dynamics in phenomena that can serve as proxies for the anomic state of a society or community. Specifically, (complex)  
146 contagion processes (see Table 1) have been observed for mental disorders and distress, including suicide (Scatà et al., 2018;  
147 Paz, 2022), for deviant behaviours (Busching and Krahe, 2018), and for distrust (Ross et al., 2022). Societies or communities  
148 that are already in a zone of social instability (e.g. high rates of anti-social behaviour, increasing deviant behaviour such as  
149 crime or substance abuse, high rates of mental health problems) due to other factors, such as poverty, rising inequality and  
150 failing institution (Burns, 2015) or because of a gradual erosion of social norms that can affect affluent communities too (Pfiff  
151 et al., 2012; Bursztyrn et al., 2020), are particular at risk to tip into an anomic state, when additionally being faced with  
152 ecological destabilisation (cf. Douglas et al., 2016). Anomie tipping can also result from a single extreme event, for instance,  
153 triggered by an ESTP being breached. Such an event can instantly disintegrate whole communities, scattering members of the  
154 community in the aftermath (i.e., interaction with displacement), leaving them with depleted social and mental resources  
155 (Miller, 2016) and establishing the perception that society as a whole is failing (Teymoori et al., 2017). Tipping in this case  
156 can be described using Logistic Map models (Bruun et al., 2017), which can model how coupled systems can tumble towards  
157 chaotic system behaviour (see Table 1). Natural and human-caused disasters can bring communities together and strengthen  
158 cooperation, however research suggests that when the experience of solidarity and unity in the disaster aftermath starts to  
159 wane, communities can experience increasing disillusionment and depression, followed by social disintegration (i.e. anomie),  
160 if they are left without adequate, long-term support (Townshend et al., 2015).

161 Anomie can have feedback effects on the Earth system, further destabilising it through various pathways. When social norms  
162 disintegrate, certain pro-social behaviours and collective actions that are necessary to slow down the climate crisis may  
163 diminish (Constantino et al., 2022; Schneider and van der Linden, 2023; Lettinga et al., 2020). Without strong social norms  
164 and social ties supporting collective action and fostering reciprocity, trust, and cooperation, it becomes increasingly  
165 challenging to implement effective measures to address accelerating Earth system destabilisation, hence increasing the  
166 likelihood for Earth system tipping (Fehr et al., 2002; Thøgersen, 2008; Malerba, 2022). Moreover, mental health problems

167 weaken people's capacity to seek solutions, fostering collective inertia and increasing susceptibility to conspiracy theories,  
168 potentially further undermining trust and cooperation to prevent further Earth destabilisation (Burden et al, 2017; de la  
169 Sablonnière & Taylor 2020; Green et al., 2023).

## 170 **2.2 Radicalisation & Polarization**

171 Radicalisation can be a reaction to perceived external threats, including ecological threats. Research suggests that people can  
172 respond to climate change and other ecological threats by becoming more authoritarian and derogative against outgroups  
173 (Fritsche et al., 2012; Jackson et al., 2019; Taylor, 2019; Russo et al., 2020; Uenal et al., 2021). This effect can be further  
174 exacerbated by the well documented effect of heat on aggressive behaviours, including online hate speech (Stechemesser et  
175 al., 2022). Current trends seem to suggest increasing polarisation (Dunlap et al., 2016; Vihma et al., 2021; Cole et al., 2023;  
176 Smith et al., 2024), i.e. a rise of the political right, which is increasingly attracting the political centre (Levitsky and Ziblatt,  
177 2018; Halikiopoulou, 2018; Layton et al. 2021), obstructing climate action and increasingly diverging from the political  
178 left/centre-left, which is demanding climate action (Aasen, 2017; Lockwood, 2018; Gustafson et al., 2019). This polarisation  
179 is driven indirectly by Earth destabilisation too, as it is at least partly a response to climate mitigation policies that are perceived  
180 as a threat to the existing socio-economic system, status and identity (Dunlap et al., 2016; Hoffarth and Hodson, 2016; Dagett,  
181 2018; Clarke et al., 2019; Benegal and Homan, 2021; Ehret et al., 2022; Brännlund and Peterson, 2024) and can be further  
182 exacerbated by inequality and general economic decline (Winkler, 2019; Stewart et al., 2020; Hübscher et al., 2023), which  
183 again can be partly linked to Earth destabilisation at least in some parts of the world (Méjean et al., 2024; Dietz et al, 2021).  
184 However, as climate change progresses and becomes a more concrete existential threat throughout the world (Huggel et al.,  
185 2022), we may see even socially liberal individuals developing increasingly authoritarian and reactionary views (Gadarian,  
186 2010; Hetherington and Suhay, 2011; Huddy and Feldmann, 2011; Hirsch, 2022). At that stage we may see radicalisation  
187 taking a different direction, with currently fringe political ideologies such as ecofascism taking hold. Ecofascism reinterprets  
188 white supremacy ideology in the context of climate/ecological crisis with the goal to defend habitable areas for the white race  
189 and decrease world population (Taylor, 2019). Already, a couple of recent right-wing terrorists have self-identified as  
190 ecofascists, such as Brenton Tarrant, who killed 51 people during a terror attack on a mosque in Christchurch, New Zealand  
191 in 2019. A few months later Patrick Wood Crusius killed 23 people in El Paso, United States, legitimising his actions again  
192 with ecofascist ideologies (Achenbach, 2019). Certain ecofascist themes seem to also appear increasingly in public debates  
193 (Thomas and Gosink, 2021).

194 Radicalisation can exhibit tipping dynamics. Research has described radicalisation, e.g., the spread of right-wing ideology  
195 (Youngblood, 2020), through complex contagion processes (see Table 1). Similarly, the spreading of extremist content on  
196 social media has been observed to follow complex contagion processes (Ferrara, 2017). Indeed, polarisation and radicalisation  
197 around climate change has been observed to be on the rise online (Weber et al., 2020; Teen et al., 2020; Falkenberg et al.  
198 2022), at times displaying non-linear, accelerating diffusion dynamics (Centre for Countering Digital Hate, 2023) and fuelled  
199 by corporate funding (Farrell, 2016; Teen et al., 2020). Moreover, processes of “cross-pollination”, the merging or previously  
200 separate radical clusters facilitating further contagion, have been documented (Kimmel, 2018; Baele et al., 2023), including  
201 for climate denial (Agius et al., 2020). Polarization has also been observed to follow tipping dynamics. Leonard et al. (2021)  
202 describe for instance for the US how subtle public opinion shifts from left and right can have a differential effect on the self-  
203 reinforcing processes of elites, causing Republicans to polarize more quickly than Democrats. As self-reinforcement pushes  
204 societies toward the critical threshold, polarisation speeds up. Political polarisation tipping, often accompanying radicalisation

205 of certain segments of the population, has been found to be difficult to reverse due to asymmetric self-perpetuating trajectories  
206 (Macy et al., 2021).

207 Radicalisation and polarisation can have feedback effects on the Earth's system, destabilising it further. According to research  
208 (Stanley et al., 2017; Stanley and Wilson, 2019; Julhä and Hellmer, 2020), authoritarian and social dominance attitudes are  
209 negatively related to environmental attitudes and support for environmental/climate change policies. Indeed, right-wing  
210 ideology has been repeatedly correlated with climate change denial (Hornsey et.al, 2016; Hoffarth and Hodson, 2016; Czarnek  
211 et al., 2020; Julhä and Hellmer, 2020). When climate change is denied, no attempts are made to mitigate climate change, on  
212 the contrary, decisions may be taken to further prop up high-emitting industries (Ekberg et al., 2023; Darian-Smith, 2023).  
213 There is however increasingly a retreat of pure climate denial (primary climate obstruction), instead we see a rise in secondary  
214 and tertiary climate obstruction, which can include deliberate polarisation of societies on the issue (Kousser and Trantr, 2018;  
215 Goldberg and Vandenberg, 2019; Lamb et al., 2020; Mann, 2021; Flores et al., 2022; Ekberg et al., 2023; Burgess et al., 2024).  
216 Research moreover demonstrates that the increasing success of the radical right influences also the policies of mainstream  
217 parties (Abou-Chadi and Krause, 2020), i.e. even if radical parties are not in government, they still can undermine climate  
218 policies.

### 219 **2.3 Displacement**

220 Acute and slow-onset environmental pressures, such as [heatwaves](#), [long-term temperature and humidity changes](#), extreme  
221 weather events and sea level rise (e.g. due to the melting of Greenland glaciers, and the West Antarctic Ice Sheet), are likely  
222 to impact the migration (voluntary) and displacement (forced, involuntary) [circumstances](#) of a large proportion of the [global](#)  
223 [population](#) (Mastorillo et al., 2016; Berlemann et al., 2020; Hauer et al., 2020; Hoffmann et al., 2020; Lu and Romps, 2023).  
224 [In the context of ESTPs](#), sea-level rise is projected to be one of the most costly and irreversible consequences of climate change  
225 (Hauer et al., 2020, McLeman, 2018, Kaczan & Orgill-Meyer, 2020; [Armstrong McKay et al., 2022](#)). Another [rapid-onset](#)  
226 [hazard](#) is [land degradation due to permafrost melt](#), both in coastal areas and inland (Irrgang et al., 2022; [Streletskiy et al.,](#)  
227 [2023](#)). [Accelerated Polar warming or Arctic Amplification](#) warms Arctic surface temperatures by a factor two-to-four times  
228 [faster than the rest of the globe](#) (Rantanen et al., 2022), which - in addition to the direct impact on permafrost thawing - results  
229 [in the loss of protective sea ice and, consequently, rapidly increasing coastal erosion](#) (Casas-Prat and Wang 2020; Nielsen et  
230 [al., 2022; Wunderling et al., 2024](#)). As the proportion of the global population living in coastal regions continues to grow,  
231 likely surpassing one billion people this century, [this will have profound implications for both individuals and societies](#) (Hauer  
232 [et al., 2020, McLeman, 2018, Kaczan and Orgill-Meyer, 2020](#)). However, sea level rise is not the only driver of adaptive  
233 [mobility](#) (Gioli et al., 2016). Even if international efforts towards mitigating climate change are successful (RCP 4.5 – low  
234 [emissions scenario](#)), models have projected drought-induced international displacement to increase substantially by the end of  
235 [the 21st Century](#). High emissions scenarios (e.g. RCP 8.5) would push the number of displaced due to droughts even further  
236 [up](#) (Smirnov et al., 2023).

237 Displacement can happen suddenly and amplifying or positive feedbacks can increase or maintain the [dislocation of](#)  
238 [populations](#) even after the extreme weather event or initial shock has passed. [This can create a cycle that reinforces, extends,](#)  
239 [or renders the displacement permanent](#). Displaced populations must grapple with the loss of their livelihoods, often by  
240 identifying new temporary sources of income that can become permanent due to the challenges of returning to origin  
241 communities (Young and Jacobsen, 2013; [Wilson, 2020](#)). [The displacement is often linked with turning away from traditional](#)  
242 [ways of life and economical support](#), e.g. in the cases of Arctic Inuit population fishing, hunting, and trapping (Ford et al.,  
243 [2023; Streletskiy et al., 2023](#)), and the movement away from traditional agricultural and pastoralist livelihoods in areas of  
244 [Central and Southwest Africa](#) (Akinbami, 2021; Thorn et al., 2023). This can result in cultural heritage loss (Pearson, 2023).  
245 These compounding and reinforcing effects can exacerbate pre-existing social inequities, and determine the pattern of

246 displacement (e.g. short or long-term/permanent) among different populations (Lama, 2021; Boas et al, 2022). Additionally,  
247 with slow-onset events, decisions to migrate can be driven by social networks and connections; when members of a community  
248 migrate, others may make the decision to follow (Manchin and Orazbayev, 2018; Thorn et al., 2023; Tubi and Israeli, 2023).  
249 This can, in and of itself, be subject to tipping dynamics; when a certain percentage of a community has left, this has been  
250 observed to negatively impact those left behind, potentially triggering subsequent outmigration (Rai, 2022).

251 In the absence of appropriate governance mechanisms and protocols for how and where to relocate displaced communities,  
252 negative feedback consequences for the Earth systems are possible (Islam et al., 2021; Thorn et al., 2023). Hosting  
253 communities may face strains on their natural resources and/or sinks to meet the additional needs of the displaced. For example,  
254 Tafere (2018) identified environmental degradation resulting from the influx of displaced populations in East Africa, often in  
255 environmentally sensitive (e.g. protected forests) or already strained regions (e.g. arid or semi-arid areas). Such straining of  
256 ecological systems to accommodate increased ecoservices demand due to forced migration could contribute to accelerating at  
257 the very least regional ecological destabilisation.

## 258 2.4 Conflict

259 Despite growing concerns about conflict, the causal link between climate change and conflicts as well as their underlying  
260 dynamics remain debated (Burke et al., 2009; Buhaug, 2010; Buhaug et al., 2014; Solow, 2013, Kelley et al., 2015; Selby et  
261 al., 2017). While statistical models inferred either significant coincidences of particular civil conflict events with concurrent  
262 climate extreme events or significant associations of warming and drought trends with civil conflict trends, many qualitative  
263 in-depth assessments of the particular civil conflict events and their underlying mechanisms dismiss such coincidences and  
264 associations (e.g. Buhaug, 2010; Selby et al., 2017). Though not the only cause (Sakaguchi et al., 2017; Mach et al., 2019;  
265 Scartozzi, 2020; Ge et al., 2022), climate change undermines human livelihoods and security, because it increases the  
266 vulnerability of populations (e.g. to extreme events, food/water scarcity), grievances, and political tensions through an array  
267 of indirect – at times non-linear and latent (i.e. not measurable) – pathways, thereby increasing human insecurity and the risk  
268 of violent conflict (Scheffran et al., 2012; van Baalen and Mobjörk, 2017; Koubi, 2019; von Uexkull and Buhaug, 2021; Ide  
269 et al., 2023). It is difficult to separate mutually enforcing vulnerabilities to both climate and conflict that trigger an escalating  
270 spiral of violence and amplify cascading crisis events beyond critical thresholds (Buhaug and von Uexkull, 2021) and  
271 connected through telecoupling (Franzke et al., 2022).

272 Many conflicts can be described in terms of social tipping mechanisms, which can be triggered by Earth system destabilisation,  
273 where causal mechanisms are inferred using data (Sun et al., 2022) and can be modelled through socially connected tipping  
274 dynamics, for instance using the logistic map approach (see Table 1) (Guo et al., 2018, Aquino et al., 2019, Ge et al., 2022,  
275 Guo et al., 2023). Using a complex systems lens and connecting the human–environmental–climate security (HECS) nexus  
276 framework (Daoudy, 2021; Daoudy et al., 2022; Scheffran et al., 2012) and the social feedback loop (SFL) framework  
277 (Kolmes, 2008) can help clarify conflict tipping mechanisms in coupled social-ecological systems. The HECS framework  
278 infers that climatic drivers of civil conflicts are best understood as a result of policy decisions and governance that reflect the  
279 ideology and preferences of ruling elites or ethnic bias instead of investigating the direct functions of climate extremes. SFL  
280 suggests that initial social disruptions directly caused by gradual climate change and climate extreme events can itself generate  
281 a distinct positive feedback loop leading to self-accelerating rates of societal disintegration and in turn to civil conflicts  
282 (Kolmes, 2008). In turn, using a combined HECS-SFL lens, civil conflicts can be perceived as amplified social disintegration  
283 and disruption resulting from societal and political responses to the initial disintegration and disruptions caused directly by  
284 climate extremes and climate change. Self-reinforcing feedbacks emerge in social-ecological systems as a result of complex  
285 interactions among socio-economic, environmental and political events and variables, such as institutional capacity for solving  
286 social-ecological problems initially caused by climate change (Daoudy et al., 2022). These complex interactions result in the

287 amplification of social-ecological shocks that climate change and extremes initially caused and potentially disrupt and  
288 negatively tip the system in concern to a conflict state. The affected system becomes entrapped in the conflict state until  
289 sufficient incentives can move it out. However, there remain gaps in understanding latent mechanisms which introduce variable  
290 delay (e.g. slow social transformations), confounding factors, non-linear bifurcations (e.g. some transformations are  
291 irreversible) and regional variability.

292 When conflicts escalate, exhibiting a tipping dynamic, they can in turn impact the Earth system, either directly as warfare itself  
293 is producing excessive GHG emissions and destroying vital ecosystems such as forests, as is for instance currently the case of  
294 Russia's war in Ukraine (de Klerk et al., 2022). For example, the Kakhovka Dam was destroyed in 2023 during the Russia-  
295 Ukraine conflict. Early assessments (UKCEH & HRW, 2023; UNEP, 2023) indicated a maximum downstream flood extent  
296 of around 83,000 hectares (6 - 9 March 2023) including inundation of downstream urban areas and disruption of irrigation for  
297 agriculture, water supply and sanitation systems. Over half a million hectares of habitat of conservation importance was  
298 estimated to have been affected by the dam breach, from the upstream Kakhovka Reservoir and its wetland habitats to the  
299 downstream Black Sea Biosphere Reserve. This impact area covered the distribution of 567 species that have a listing on the  
300 IUCN European Red List, 28 of these species have a threat status of vulnerable or worse. There were also concerns about the  
301 supply of cooling water to the upstream Zaporizhzhia Nuclear Power Plant, i.e. one war-induced ecological disaster could have  
302 resulted in another ecological disaster. Illegal logging, deforestation and charcoal production also support militia in many  
303 protracted conflicts throughout Africa (Branch et al., 2023). But, even beyond involvement in war activities, everyday military  
304 operations directly generate vast emissions of GHGs (Kester and Sovacool, 2017; Crawford, 2019). The feedback impact of  
305 conflicts on the Earth system can also occur indirectly through impeding humanity's ability to collaborate to find solutions to  
306 global challenges such as climate change. Within societies entangled in a conflict, resources are diverted to winning the conflict  
307 rather than to mitigate climate change, also affecting a country's environmental governance mechanisms. Finally, the continued  
308 presence of a large number of tactical and nuclear weapons represents a significant threat to global climate and other Earth  
309 system processes (Turco et al., 1983; Xia et al., 2022).

## 310 **2.5 Financial Destabilisation**

311 The impacts of Earth system destabilisation on the financial sector are now receiving increasing attention, with studies  
312 suggesting that climate-related damages will impact the stability of the global banking system significantly (Lamperti et al.,  
313 2019), as can biodiversity loss (Kedward et al., 2023). For instance, stocks of capital at risk due to climate-induced extreme  
314 and more frequent weather events such as floods, would adversely affect insurance companies (Lamperti et al., 2019).  
315 Reinsurance companies are withdrawing increasingly from areas exposed to high climate change risks, e.g., areas vulnerable  
316 to wildfires and floods (Frank, 2023). Earth system destabilisation is likely to result in stranded assets (Caldecott et al., 2021).  
317 Escalating climate change can also destroy the capital of firms, reduce their profitability, deteriorate their liquidity, reduce the  
318 productivity of their workforce, leading to a higher rate of default, harming the financial sector and the economy in general  
319 (Dafermos et al., 2018; Dietz et al., 2021). One issue with the existing empirical evidence and models that try to estimate  
320 climate damage for the financial sector is however that they do not account for ESTPs (Keen et al., 2022; Trust et al., 2023).

321 Still, first advances are being made. Martin et al. (2024) propose an Integrated Dynamic Environment-Economic model on the  
322 coupling of an Earth Model of Intermediate Complexity and a non-linear macroeconomic model in continuous time. Using  
323 this model, they found that above a warming of about +2.3°C, damages drastically foster the need for additional investments  
324 in productive capital for adaptation, which could potentially lead to the emergence of private-debt tipping points and a  
325 worldwide cascade of defaults. The inability to repay obligations generates non-performing loans (or bad debt) in the balance  
326 sheets of banks and other financial institutions, with possible systemic implications such as those experienced during the 2008  
327 global financial crisis. It is estimated that climate change will increase the frequency of banking crises by 26% to 248%

328 depending on the extent of climate change (Lamperti et al., 2019). If the banks' equity deterioration due to economic  
329 imbalances reaches a certain threshold, secondary systemic effects can be triggered. Financial institutions exposed to troubled  
330 banks would suffer losses in the market value of their assets, potentially triggering contagion phenomena (Kiyotaki and Moore,  
331 2002; Yan et al., 2010; Roukny et al., 2013; Chinazzi and Fagiolo, 2015). These contagion phenomena can result in a financial  
332 tipping point being reached, when contagion becomes self-perpetuating due to feedback loops in the system that amplify the  
333 initial shocks (Haldane and May, 2011; May et al., 2008, Gai and Kapadia, 2010). If ESTPs are triggered, destroying assets  
334 and the economic productivity of whole regions, we can expect rapid non-linear tipping effects in the coupled financial sector  
335 (Battiston et al., 2017). The financial and economic system would eventually settle into a new state, although this state may  
336 be characterized by recession, high unemployment, austerity, and other deteriorating economic conditions. The consequences  
337 of such a financial [upheaval](#) are often a rapid increase in social instability (i.e. interaction with anomie), increase in  
338 radicalisation (i.e. interaction with radicalisation) as more people are forced to compete for basic needs (i.e. interaction with  
339 conflict) (Dietz et al., 2021).

340  
341 [This could also impact societies' abilities to mitigate climate change, thus risking the derailment of sustainability transition](#)  
342 [\(Laybourn et al., 2023\)](#). Governments will likely try to stabilise financial markets through bailing-out policy such as providing  
343 fresh capital and saving insolvent banks and it is predicted that climate change will likely increase the frequency of bailouts  
344 (Lamperti et al., 2019). Recent government bailouts in response to COVID-19 have shown a distinct lack of sustainability  
345 focus (Rockström et al., 2023). Bailouts negatively affect the public budget and lead to increasing government debts, leaving  
346 decreasing resources for addressing Earth system destabilisation, for instance through effective climate change mitigation  
347 measures. Financial destabilisation would also deplete businesses and individuals of resources to invest in post-carbon  
348 transition (Laybourn et al., 2023).

### 349 **3 Cascading Negative Social Tipping Dynamics**

350 [The basis for many tipping point behaviours in social-ecological systems is a non-linear relationship between critical pairs of](#)  
351 [variables. Non-linearities create disproportionate relationships between cause and effect, potentially leading to change that is](#)  
352 [faster, more intense, or more extensive than expected \(and hence, harder to reverse or control\). Cascades, as defined by Klose](#)  
353 [et al. \(2021\), are sequential occurrences of events in which an initial event triggers a series of subsequent events and are one](#)  
354 [important attribute of systemic risk \(Sillmann et al., 2022\). Cascades are more likely when multiple variables within a given](#)  
355 [system exhibit and transform non-linear relationships to each other, i.e. when coupled, these relationships transform in ways](#)  
356 [that often cannot be understood. Crossing multiple negative tipping points in diverse systems increases the likelihood of \(partial](#)  
357 [or localised\) societal collapse.](#)

358 In the context of migration, this can manifest as a domino effect, where an environmental or socio-political event causes  
359 involuntary displacement or voluntary migration as people search for improved living conditions and better economic  
360 opportunities. This is well documented in the Lake Chad Basin case where climate change and unsustainable resource  
361 management affect the sustainability of natural resources, increasing vulnerability and leading to coping strategies such as  
362 migration (McLeman et al., 2021). [In Ukraine, the war-induced ecological devastation in the aftermath of the Kakhovka Dam](#)  
363 [destruction has displaced thousands of people, and a major humanitarian programme was initiated in response \(WHO, 2023\).](#)

364 A possible tipping cascade can be identified between [climate change, food insecurity, and migration](#). The last five years have  
365 seen an increase in food insecurity, representing a problematic reversal of the progress done since the 1990s to reduce world  
366 hunger (FAO et al., 2022). Climate tipping points could dramatically impact food security through direct impacts on production  
367 (availability) and indirect impacts on access to food when displacement occurs. One of the most direct ways in which tipping

368 points can affect food insecurity is through changes in rainfall distribution, which would render agricultural livelihoods in  
369 rainfed regions unfeasible without irrigation (or other) technologies (Giannini et al., 2017; Benton et al., 2017). Indeed, even  
370 in the most optimistic climate mitigation scenarios which would lead to a temporary overshoot over 1.5°C, and then return to  
371 temperatures below that threshold, a tipping point might occur in precipitation patterns which can result in adverse food  
372 security impacts (cf. Ritchie et al., 2020). Additionally, recent studies suggest that escalating climate change could result in  
373 concurrent weather extremes driven by a strongly meandering jet stream, which could trigger simultaneous harvest failures  
374 across major crop-producing regions, posing a serious threat to global food security (Kornhuber et al., 2023). Food security  
375 can change seasonally. As such, food security does not exhibit traditional bifurcation in the sense of irreversibility. However,  
376 a permanent change towards a state of food insecurity would be catastrophic, representing a permanent food crisis.  
377 Krishnamurthy et al. (2022) offer a framework to identify “transitions” as prolonged periods of food insecurity (Figure 3),  
378 using the Integrated Food Security Phase Classification (IPC), the leading global metric for standardized food security  
379 assessment, which combines data on agricultural production, food prices, nutrition rates, weather patterns, and other variables  
380 to determine the general food security situation in a given location. With these metrics, a tipping point in a food system can be  
381 thought of as a shift between periods with minimal food insecurity (IPC 1 or 2) to periods of sustained food crisis (IPC 3 or  
382 higher). An example of a potential tipping point using the IPC categories was found in East Africa in 2015/2016 due to  
383 anomalously low rainfall in both the summer and autumn. This trend, combined with insufficient drought preparedness,  
384 resulted in crop failures and livestock mortality—and consequently a depletion of livelihood assets, food stocks, and overall  
385 food security in northern and eastern regions of Ethiopia (Figure 3).

386

387 [FIGURE 3 HERE]

388 The links between food insecurity and migration are complex, severe food insecurity has been found to trap people locally,  
389 who wish to migrate, but are unable to (Sadiddin et al., 2019) but there is also evidence that migration can be driven by food  
390 insecurity (Smith and Wesselbaum, 2022). Migration flows are also impacted by climate change directly (i.e. the local  
391 environment becomes unsuitable for favourable habitation) and indirectly (i.e. by impacting relative wages through effects on  
392 farmers’ crop yields). A climate disaster, for instance triggered by a climate tipping point being breached, may also lead to  
393 sudden displacement, whether temporary or permanent. To summarise, a cascading dynamic plays out when various tipping  
394 points become coupled, for instance, when the tipping in an Earth system, triggers the tipping in food insecurity and potentially  
395 simultaneously a tipping in displacement, which in turn may reinforce food insecurity.

396 Other potential cascading links exist as well, for instance, societies may tip into a state of conflict because of competition over  
397 dwindling resources as tipping in food insecurity occurs and conflicts in turn may reinforce food insecurity, a cascade made  
398 likely when institutions are weak, and governance fails (Martin-Shields and Stojetz, 2019; Anderson et al., 2021; Shemyakina,  
399 2022). Radicalisation and polarisation can fuel conflicts (McNeil-Willson et al., 2019; Rousseau et al., 2021), radicalisation  
400 and polarisation has been also observed in countries hosting displaced communities (Ravndal, 2018), a link often moderated  
401 by socio-economic inequality and perceived insecurity. Radicalisation, polarisation, and anomie can reinforce each other too.  
402 Research suggests for instance that in countries with greater polarisation, people trust each other less (Rapp, 2016). On the  
403 other hand, people with mental health issues are more susceptible to conspiracy theories, which can fuel radicalisation (Green  
404 et al., 2023). Finally, financial destabilisation can be a driver for radicalisation, polarisation, and anomie (Funke et al., 2016;  
405 Bygnes, 2017; Doerr et al., 2022). However, these and other potential cascading links and processes, are still little researched  
406 and understood.

## 407 4 Emerging research questions and intervention options

### 408 4.1 Methods and models and emerging data questions

409 Various methods and approaches have been suggested for the study of tipping processes in social and socio-ecological systems,  
410 which can be used to study negative social tipping points and the cascading interactions between them. In Table 1 we discuss  
411 the most prevalent methods and some new emerging approaches. We would like to emphasise here that we are not suggesting  
412 that negative social tipping points are knowable in advance, in terms of determining or predicting the exact threshold or time  
413 when a tipping will occur. In fact, the knowability of tipping points is a challenge not only for social tipping points but equally  
414 for ESTPs (Boulton et al., 2023). It is usually only possible to determine a tipping point subsequently. However, even then  
415 there is often not a single negative social tipping point, the exact threshold may vary for instance from one country to another  
416 or from one community to another (e.g. c.f. Spaiser et al. 2018 deriving from data specific segregation tipping points for  
417 various schools, located on a curve), as the setup of reinforcing and dampening feedbacks will be different in every context.  
418 This is also true for some ecological tipping points; e.g. different lakes will have different tipping points (Hessen et al., 2023)  
419 The methods we are suggesting here are useful (1) to study tipping processes, once they have occurred or to generate various  
420 model-based scenarios to build our general understanding of tipping processes, so we are better equipped to respond to them  
421 and (2) to build early warning systems that could potentially capture a system becoming more unstable, chaotic or exhibiting  
422 more unusual behaviour before a tipping point has been reached. The purpose is to increase our agency (see 4.2).

423  
424 We are also conscious that all models are oversimplification of many stories and perspectives and detailed mechanisms.  
425 Tipping models can be higher dimensional to capture more dimensions. But even a low dimensional tipping model, such as a  
426 neural network (see Table 1), can be used to inform the tipping parameters. In effect a simple model is a projection of more  
427 complex mechanisms in a function space. The question is how much information we lose in projecting to a tipping model,  
428 comparing to a projection to a different model. The question is also how useful the projection is in enhancing our understanding  
429 and in determining agency pathways. We believe tipping model development is important to advance our understanding and  
430 enhance our agency, but we also advocate to comparing different models (i.e. different projections) to find the “wrong”, but  
431 most useful model.

432 [TABLE 1 HERE]

433 Further emerging data questions include:

- 434 ● What are the most relevant and appropriate datasets for early warning of negative social tipping points? Social tipping  
435 points are more complex than physical tipping points due to the interacting relationships between climate parameters  
436 and social responses. Given this complexity, there is a need to identify relevant data sources and methods that can be  
437 used to detect and anticipate tipping points. Recent advances in machine learning and increasing digital social data  
438 all offer an unprecedented opportunity to understand early warning signals for social tipping points. Once datasets  
439 are identified, ensuring that these are accessible and usable for analysis is highly important. Moving forward, it will  
440 be important to consider sharing platforms to ensure access.
- 441 ● What are the characteristics of datasets that can render them more (or less) useful for detecting social tipping points?  
442 A key, practical question for tipping point analysis is whether there are specific characteristics that make datasets  
443 more appropriate for detection of critical transitions. Early warning of tipping points ultimately depends on reliable,  
444 high-frequency data (Scheffer et al. 2009, Dakos et al. 2015). For example, in an analysis of data requirements for  
445 early warning of food security tipping points, Krishnamurthy et al. (2020) highlighted the importance of temporal  
446 resolution over spatial resolution to detect autocorrelation or flickering in coupled climate-food systems. However,

447 research has shown that even limited datasets such as Soil Moisture Active Passive (SMAP) can provide game-  
448 changing opportunities for detecting food security transitions (Krishnamurthy et al., 2022).

- 449 ● Which early warning signals are more meaningful for different applications? Identifying the most useful metrics and  
450 statistics for early warnings of tipping points translates to actionable information, but it requires a clear understanding  
451 of underlying system functioning and mechanisms. For instance, in food security applications, autocorrelation is the  
452 key metric used to detect a transition in food security states, with the rolling average statistic indicating the direction  
453 of the transition (Krishnamurthy et al., 2022). Such insights can help leverage resources in a timely fashion to avert  
454 negative effects associated with social systems that exhibit tipping points.
- 455 ● Moreover, probabilistic insights from research on collective social dynamics may complement insights from new  
456 early warning signals for social tipping. These approaches identify measurable qualities of social systems or networks,  
457 such as heterogeneity, connectivity and individual-based thresholds that make social tipping points more likely  
458 (Bentley et al., 2014). For maximum efficacy, these modelling efforts should derive from both qualitative and  
459 quantitative methods so as to benefit from both data and lived experience.

#### 460 **4.2 Intervention options and emerging policy questions**

461 Given that negative social tipping points are under-researched, there is little knowledge on how they can be prevented or  
462 managed. As noted for instance by Milkoreit (2023), social tipping point governance has not really been developed yet. In  
463 Table 2 we nevertheless provide a preliminary overview of potential intervention options, linked to the discussed negative  
464 social tipping points and their main potential interactions. Future research needs to focus on identifying other potential  
465 intervention options and tying these together into a coherent tipping points governance framework. Ultimately, effective  
466 governance of negative (social) tipping points will hinge upon the understanding of collective social dynamics and proactive  
467 resource-based interventions. [The main line of agency we would like to emphasise is the strengthening of societal institutions  
468 and polycentric governance mechanisms \(Carlisle and Gruby, 2019; Morrison et al. 2023\). We also would like to emphasise  
469 agency in driving positive social tipping processes that improve long-term sustainability and well-being of people and planet  
470 \(Gaupp et al., 2023\) and prevent societies sliding into negative social tipping dynamics.](#)

471 [TABLE 2 HERE]

472 Further emerging policy questions include:

- 473 ● How do multiple climate extremes and other shock and stressors combine, especially do slow onset climate change  
474 processes drive systemic changes and tipping points? Evidence provided here, suggests that severe climate events,  
475 such as droughts and hurricanes, can result in highly complex social change, including negative social tipping points.  
476 Additional research is required to understand if and how climate and social tipping points interact, and whether one  
477 tipping point can result in a plethora of other transitions.
- 478 ● As critical transitions unfold, how does the risk landscape shift in response? Societies respond to environmental stress  
479 and resource scarcities. However, these responses may lead to new risks. Understanding how critical transitions affect  
480 the current (and future) risk landscape can provide essential information for decision-makers to prioritize investments  
481 in adaptation and mitigation.
- 482 ● What are the processes required to integrate research into policy making? There is growing research on early warning  
483 signals for tipping points. However, once suitable datasets and early warning diagnostics are identified, what are the  
484 enabling processes and steps required to integrate actionable early warning systems into decision-making? New data  
485 analytics, dashboards and communications material may go a long way towards facilitating the transition to early  
486 warning systems of tipping points that can translate into action.

## 487 **5 Conclusion**

488 We mapped selected key potential negative social tipping points and their potential cascading interactions. We have also briefly  
489 discussed potential intervention options and provided examples of methods and models that need to be advanced in the future.  
490 We do not claim to have captured all possible social negative tipping points in the context of Earth system destabilisation, and  
491 we acknowledge that other social subsystems could experience negative tipping points as well, e.g. breakdown of (certain)  
492 global supply chains (Marcucci et al., 2022), or breakdown of the public health system (at least in certain areas) triggered for  
493 instance by a massive freak heat event or the breakout of a disease due to climate change (Sharma 2023, Skinner et al., 2023).  
494 Our goal is to highlight that if societies fail to stabilise the Earth system through decarbonisation, land use reallocation and  
495 other measures, societies will not merely stay in the business-as usual state. Through mechanisms of negative social tipping  
496 accompanying further Earth system destabilisation, they instead risk transitioning into a new social system state, which may  
497 be characterised by greater impoverishment, authoritarianism, hostility, discord, violence, conflict, and alienation. Societies  
498 more vulnerable to climate change are likely to experience such negative social tipping sooner, but this will inevitably have  
499 knock-on effects globally. It is increasingly likely that in some regions large-scale climate adaptation will need to be  
500 undertaken to reduce vulnerabilities to the current and future magnitude of climate change.

501 The acceleration of climate tipping points perpetuates a vicious cycle that weakens societies and their abilities to respond,  
502 feeding further Earth system destabilisation. This vicious cycle is also fed by widening socioeconomic inequalities (Millward-  
503 Hopkins, 2022). As the consequences of climate change intensify, societal trust, cooperation, and altruism may erode due to  
504 increased competition for scarce resources, displacement of populations, and other climate-related challenges. Our knowledge  
505 on negative social tipping points is still very patchy and fragmented, with many estimations and models likely to be  
506 underestimating the effects of breaching Earth system tipping points. This is particularly true for economic and financial sector  
507 models. Researchers (Keen et al., 2022) are advocating for developing future loss calculations in close collaboration with  
508 climate scientists to ensure adequate representation of climate catastrophes.

514 [Viktoria Spaiser](#) acknowledges support from the [UKRI Future Leaders Fellowship](#) award (MR/V021141/1).

515 [Yevgeny Aksenov](#) and [Stefanie Rynders](#) acknowledge support from the following projects: COMFORT (grant agreement no.  
516 820989) under the European Union's Horizon 2020 research and innovation program; the EC Horizon Europe project  
517 OptimESM "Optimal High Resolution Earth System Models for Exploring Future Climate Changes" under grant 101081193  
518 and UKRI grant 10039429; EPOC, EU grant 101059547; UKRI grant 10038003; and the UK NERC projects LTS-M  
519 BIPOLE (NE/W004933/1), CANARI (NE/W004984/1), and Consequences of Arctic Warming for European Climate and  
520 Extreme Weather (ArctiCONNECT, NE/V004875/1). [Yevgeny Aksenov](#) and [Stefanie Rynders](#) acknowledge the use of the  
521 ARCHER UK National Supercomputing and JASMIN.

522 [Weisi Guo](#) acknowledges support from EPSRC Complexity Twin for Resilient Ecosystems (EP/R041725/1).

523 [Jürgen Scheffran](#) and [Jana Sillmann](#) acknowledge support under Germany's Excellence Strategy—EXC 2037: "CLICCS—  
524 Climate, Climatic Change, and Society"—Project Number: 390683824 funded by Deutsche Forschungsgemeinschaft.

525 [Uche Okpara](#) acknowledges support from the UKRI Future Leaders Fellowship Award (MR/V022318/1)

529 John T. Bruun gratefully acknowledges the UK Research Councils funded Models2Decisions grant (M2DPP035:  
530 EP/P0167741/1), ReCICLE (NE/M004120/1), and STFC Spark Award (ST/V005898/1), which helped fund his involvement  
531 with this work.

**Table 1. Models and Methodological Approaches for Studying Negative Social Tipping Points and Cascades**

Model/ Approach	Rationale	Modelled phenomena	Examples	Further Questions
(Complex) Contagion Processes on (Social) Networks	In a simple contagion direct exposure to a viral entity (beliefs, behaviours, emotions, price signals) is sufficient for a node to get “infected”. In a complex contagion a node gets “infected” if a certain number (can be heterogeneous) of its neighbour nodes are infected (Guilbeault et al., 2018; Wiedermann et al., 2020; Andreoni et al., 2021). Models of contagion on networks can be used to study radicalisation, anomie, and financial tipping.	In a contagion a viral entity spreads initially gradually until a critical threshold (critical number of “infected” nodes) is reached at which stage the social system tips through saddle-node bifurcations and hysteresis. Hysteresis ensures that the contagion spreads further and leads to the phase transition, even if the original seeders of the viral entity are removed from the network, i.e., the contagion processes become self-reinforcing (Dodds and Watts, 2004; Wiedermann et al., 2020; Xie et al., 2021). Network structure (e.g. clustering) can facilitate or prevent various contagion processes (Guilbeault and Centola, 2021).	Research shows that beliefs (incl. misinformation), mental states, behaviours and practices (e.g. technology adoption) can spread through complex contagion across social networks (Karsai et al., 2014; Törnberg, 2018; Fink et al., 2021; Xie et al., 2021; Alexander et al., 2022). Research on financial contagion also shows that volatility can spread across a network of financial institutions (Summer, 2013; Wunderling et al., 2021).	There are gaps in our understanding of the mechanisms underlying complex contagion in the real world, where at any given time multiple, conflicting diffusion processes are taking place (Min and Miguel, 2018; Vasconcelos et al., 2019; Yletyinen et al., 2021).
Logistic Maps Models	The logistic map is a mathematical function that models the population change of an ecosystem over time and it is a useful tool for policy and climate analysis as it represents a wide range of regular and chaotic features (Feigenbaum, 1980; Bruun et al., 2017). Logistic Maps can be used to study anomie social tipping and cascading dynamics for instance in financial and political systems (incl. conflicts).	The logistic map provides the capability to investigate non-abrupt and/or reversible tipping point changes that are features of the system. It represents the socio-economic system through the population level, at time $t$ , as $X_t$ , and its future population state at time $t+1$ is specified by the non-linear relationship $X_{t+1} = r X_t (1 - X_t)$ . It enables us to identify and explore tipping point transitions and complexity cascades properties across a set of different system types.	<a href="#">Logistic maps have been used to model financial and economic cycles and crises (Ausloos and Dirickx, 2006; Guégan, 2009).</a> <a href="#">Logistic maps have also been employed to study conflicts (Guastello, 2008; Scheffran and Hannon, 2007).</a>	The model could be useful to study phenomena such as anomie, where the ecological and social system are closely coupled and the tipping in the ecological system would have direct repercussions for the social system with one possible outcome being disintegration of the social system, i.e. chaotic, random and irregular behaviour of the social system.
Causal Loop Diagrams (CLD) and Causal Inference	Causal loop diagrams (CLD) are a structural approach for systemic risk assessment on different scales and to identify whether a society is at risk of reaching a negative social tipping point (Groundstroem and Juhola, 2021; Sillmann et al., 2022). Causal inference is the attempt to empirically test causal assumptions. CLDs and causal inference can be used to study displacement, conflicts, and cascading dynamics.	CLDs map out the structure of a system and its networks and reveal causalities and feedbacks within the system (Haraldson, 2004; Sanches-Pereira and Gómez, 2015). Variables are connected with arrows that indicate positive or negative causal links between them. Links between variables may have temporal delays (Sanches-Pereira and Gómez, 2015). Feedback effects arise when variables affect each other in a cascading manner, ultimately leading back to a previous variable, creating a feedback loop. This loop can be either reinforcing (R), leading to unbounded growth or decline, or balancing (B), if some variables create counteracting changes, resulting in equilibrium.	CLDs have been used to model socio-ecological system dynamics, for instance the coupling of climate change, food insecurity and societal collapse (Richards et al., 2021). Causal inference has been used to model for instance climate induced conflict as an excitation causal process (Sun et al., 2022). Machine learning methods have also been used for causal inference, i.e. to self-discover causal trees between Earth system and social systems, <a href="#">including climate conflict</a> (Ge et al., 2022).	Improving causal understanding of how changes in the Earth system affect social systems is challenging when many of the latent mechanisms and pathways lack data, and when different regions experience diverse mechanisms. End-to-end causal inference has limited success (Guo et al., 2023).

Multi-Stable Differential Equation Models	<p><a href="#">Approaches building on mathematical dynamical systems theory</a> (Hirsch et al., 2012), analyse time series data to identify possible phase transitions from stability to instability until a new equilibrium is found. Differential equation models can have multiple equilibrium points, where the rate of change of a variable (e.g. degree of cooperation) does not change further. These models can be used to study negative social tipping phenomena, where sufficient time-series data is available, e.g. conflicts and financial systems tipping.</p>	<p>The specific functional form of the models can vary depending on the studied phenomenon. A tipping model can be for instance a 3<sup>rd</sup>-order polynomial in the form of a bi-stable ordinary differential equation (ODE): <math>dx/dt = x(x-C)(x-K)</math>. Here, we can see that the rate of change (<math>dx/dt = 0</math>) has three equilibrium points: <math>x=0</math>, <math>x=C</math>, <math>x=K</math>. Two of the three equilibria are stable, i.e. a small perturbation will cause the system to return to the closest point 0 (conflict) or <math>K&gt;C</math> (cooperation). One of the three is unstable, i.e. a small perturbation will cause the system to deviate away completely (this is the tipping criticality point C).</p>	<p>Multi-Stable Differential Equation Models have been also used for assessing the risks of emerging tipping cascades in interconnected climate tipping elements (Krönke et al., 2020; Wunderling et al., 2023) and financial systems (Wunderling et al., 2021) using Monte Carlo approaches to propagate parametric and structural uncertainties. They have also been used to study conflict dynamics (Aquino et al., 2019).</p>	<p>The models rely on rich and dense multiple time-series data. They are also constrained in terms of complexity representation. This results partly from their aggregate nature, as they are mainly concerned with macro-level dynamics; as such they might be less suitable where micro-level interactions are of interest.</p>
Agent-Based Modelling (ABM)	<p>Agent-Based Modelling (ABM) represents the rule-based behaviour and interaction of individual agents which ranges from simple homogenous to complex heterogeneous agents characterised by diverse response functions regarding their motivation and reasoning, capability to act and adaptive learning, perception, and anticipation of changing environmental situations (BenDor and Scheffran, 2019). ABM can be used to study conflicts and cascading dynamics.</p>	<p>Multiple agents show collective behaviour via opinion dynamics, coalition formation, network building, inducing social feedback, structural shifts, social norms, and transformative policies, including the transition between conflict and cooperation (Juhola et al., 2022). ABM captures macro-scale phenomena from micro-scale interactions among many heterogeneous adaptive and learning agents with bounded rationality (Filatova et al., 2013; Weber et al., 2023).</p>	<p>ABM is applied to study agents' adaptation behaviour and the possible limits to adaptation (Juhola et al., 2022). ABM approaches are well suited to model game-theoretical approaches to predict agent-induced tipping points when collaboration for instance breaks down (Grimm and Schneider, 2011). They can simulate self-reinforcing chain reactions and cascading effects in dynamic social networks (BenDor and Scheffran, 2019).</p>	<p>Where ABM lacks empirical foundation (i.e. insufficient data for large number of agents), it is difficult to verify the predictions they are making. They can be useful to generate hypotheses and explore theoretical mechanisms, which should be tested empirically.</p>
Machine Learning (ML)/AI	<p>Machine Learning (ML) approaches have been already mentioned in the context of previous sections (causal inference). But ML methods can also be used to explicitly detect tipping points (Bury et al., 2021). ML can be used to study negative social tipping phenomena, where sufficient time-series data is available, e.g. conflict, financial systems tipping etc. (<a href="#">Ge et al., 2022</a>) <a href="#">Generative AI is also discussed for the purpose of generating in-silico data (fine-tuned by human data)</a> (<a href="#">Argyle et al., 2023</a>; <a href="#">Park et al., 2023</a>; <a href="#">Törnberg et al., 2023</a>), e.g. <a href="#">high-dimensional, dynamic social network data for in-silico large-scale experiments, mimicking real life and real people, to study otherwise difficult to study phenomena, such as negative social tipping processes.</a></p>	<p>ML models have been used for instance to model bifurcations, i.e. the divergence of an outcome trajectory. These are often mechanism-informed ML models. Hawkes excitation model has been used for instance to model the coupling between successive improvised explosive device (IED) attacks and security retaliation (Tench et al., 2016). Point process modelling has been used to identify complex underlying processes in conflicts, such as diffusion, relocation, heterogeneous escalation, and volatility (Zammit-Mangion et al., 2012).</p>	<p>ML approaches can be useful to forecast tipping in conflicts for instance (Guo et al., 2018). With increasing availability of rich digital data, negative social tipping processes (e.g. radicalisation or social disintegration) could be detected using for instance Deep Learning models in combination with social network analyses (Gaikwad et al., 2022). ML-based tools are also emerging to predict tipping in financial systems (Samitas et al., 2020)</p>	<p>Pure data driven prediction models (e.g. using Gaussian Processes, Deep Recurrent Neural Networks), typically lack the ability to model irreversible transformations, such as tipping and understand causal relation strength. But if sufficient data is available and if the ML models are informed by theory and deep understanding of the underlying mechanisms (Guo et al., 2018) they can be a useful method.</p>

**Table 2 Negative (social) tipping points and options for prevention and impact management**

Negative (Social) Tipping Points	Prevention Options	Impact Management Options
Earth System Tipping Impacts (e.g. food insecurity)	Early warning systems to detect escalating food insecurity and anticipatory action mechanisms, incl. investment in irrigation, crop diversification and investment in long-term adaptation options to improve climate-smart agriculture (Krishnamurthy et al., 2020)	Risk finance (e.g., weather index insurance) (Benso et al., 2023) and emergency response (e.g., food assistance), managed relocation from areas that become uninhabitable/uncultivable (Ferris and Weerasinghe, 2020).
Anomie	Strengthening resilience of individuals and communities (Ogunbode et al., 2022). Strengthening social cohesion (Orazani et al., 2023). Ensuring authorities can respond to ecological hazard effectively through capacity building and resilient infrastructure (Miller, 2016; Brown, 2020)	Mental health support to individuals and communities affected by extreme weather events and displacement (Wood and Kallestrup, 2021). Working with affected communities to re-build and integrate displaced communities in host communities (Hawkins and Maurer, 2011)
Radicalisation & Polarisation	Preventing the spread of misinformation/disinformation (Aïmeur et al., 2023). Psychological inoculation against misinformation/disinformation (Van der Linden et al., 2017). Monitoring radicalisation. Radicalisation prevention programmes. Public engagement in democratic, deliberative decision making (Devaney et al., 2020).	Deradicalization and dialogue building programmes (Kimmel, 2018; Hangartner et al., 2021). Containing the influence of radical groups (Flache et al., 2017). Early warning systems for detecting the potential for violence (Guo et al., 2018).
Displacement	Early warning systems and anticipatory action mechanisms, e.g. managed relocation. Investing in resilience of displaced communities, through stability, education, and employment opportunities (Ferris and Weerasinghe, 2020).	Host community and refugee support (e.g., humanitarian support, food aid, housing, mental health support) (Pearce et al., 2017). Financial compensation for host communities. Legal frameworks and policies to support mixed movements (McAdam, 2012)
Conflict	Conflict early warning systems (CEWS) (Guo et al., 2018). Conflict prevention processes, through conflict management and democratic procedures. Agreements on scarce resource management and distribution. Climate change adaptation support. Resilience building of societies at risk of violent conflict (Abrahams, 2020). Conduct conflict risk assessment of critical infrastructure identifying impact cascades across rural, urban and natural environments to inform redevelopment or security measures to mitigate risks.	Conflict resolution process (Ngaruiya and Scheffran, 2016). Humanitarian support to citizens trapped in conflicts. Managed relocation from active fighting zones. <a href="#">Provision of evidence to support post-conflict reconstruction and recovery building. Provision of clean water, sanitation, hospitals, and schools. Biodiversity recovery planning to restore critical habitats and species, including those of high economic value to support social recovery.</a>
Financial Destabilisation	Early and stable transition away from fossil fuel assets (i.e. divestment). Implementation of a green corporate quantitative easing programme to reduce climate-induced financial instability and restrict global warming (Lamperti et al., 2019)	Macroprudential regulation in climate risk management. A counter-cyclical capital buffer (as proposed in the Basel III framework) could help address climate physical risks, even though it may be insufficient when damages surge (Lamperti et al., 2019)
Cascading dynamics	<a href="#">A big potential lies in recovery and reconstruction efforts that have the goal to build resilience to prevent future negative social tipping points cascading (Hanson, 2018). During recovery and reconstruction planning, options for climate change adaptation and biodiversity recovery may provide a level of risk management for future conflict and natural disasters (e.g. adapting to future flood risk in the lower Dniro basin caused by climate change in Ukraine). An approach to assessing impact cascades may be transferable to risk assessment and mitigation of natural disasters globally (Ward et al., 2020). The United Nations Disaster Risk Reduction (UNDRR) Programme Framework may provide a starting point for such an approach (UNDRR &amp; ISC 2020).</a>	<a href="#">Overall, management options for cascading impacts have been studied relatively little. Management options depend greatly on the type of cascading impact and the systems between which it occurs. In general, collaborative governance, bilaterally or multilaterally, between governing entities can yield better outcomes.</a>
