Inverse modelling – analytical solution

8 Our inverse modelling method, like most, uses Bayesian theory in order to adapt the surface
9 fluxes of CH₄ used in the TOMCAT model to produce the optimised model – observation

10 comparison. These methods usually assume that the model variables to be optimised,

11 contained within a state vector \mathbf{x} , have associated uncertainties of Gaussian distribution. This

12 assumption allows the model – observation mismatch to be described via a cost function J(x)13 as follows:

14

15

16

$$J(\mathbf{x}) = \frac{1}{2}(\mathbf{x} - \mathbf{x}_b)\mathbf{B}^{-1}(\mathbf{x} - \mathbf{x}_b) + \frac{1}{2}(\mathbf{y} - \mathbf{H}\mathbf{x})\mathbf{R}^{-1}(\mathbf{y} - \mathbf{H}\mathbf{x})$$
(1)

Here, the vector \boldsymbol{y} contains the observations, whilst the matrix \boldsymbol{H} represents both the model 17 18 transport and chemistry acting on the variables within the state vector, and the action of mapping the model output onto the observation space. The observation error covariance 19 matrix \mathbf{R} contains on its diagonal the uncertainties associated with the observations, model 20 21 and model's representation of the observations. The off-diagonals contain the covariances 22 between these uncertainties. Since these problems are generally under-constrained but the observational data, we also include an *a priori* estimate of the state vector, x_b , and its own 23 24 associated error covariance matrix \boldsymbol{B} . Minimising this cost function provides a solution that 25 provides the best possible match between the model and the observations whilst remaining as

close as possible to the *a priori* assumptions for the variables in the state vector.

27

28 There are various methods available to solve this minimisation problem, which can be

29 difficult to achieve for larger problems with large matrices to invert. For such instances,

30 TOMCAT has an iterative variational scheme, INVICAT, available (Wilson et al., 2014).

31 However, the Nord Stream optimisation problem documented here is small enough that

32 Equation (1) can be solved directly with basic computing software. The *a posteriori* solution 32 for the state water t_{i} as decompared by Tarantals and Valette (1082) can be solved for by

for the state vector \mathbf{x}_a as documented by Tarantola and Valette (1982) can be solved for by assuming that the gradient of $J(\mathbf{x})$ is zero, as follows:

35 36 37

$$\boldsymbol{x}_{a} = \boldsymbol{x}_{b} + [\boldsymbol{H}^{T} \boldsymbol{R}^{-1} \boldsymbol{H} + \boldsymbol{B}^{-1}]^{-1} \boldsymbol{H}^{T} \boldsymbol{R}^{-1} (\boldsymbol{y} - \boldsymbol{H} \boldsymbol{x}_{b})$$
⁽²⁾

38 whilst the *a posteriori* error covariance matrix **A** is given by:

- 40 $A = [H^T R^{-1} H + B^{-1}]^{-1}$
- 41

39

42 We use separate 'tagged' tracers in the model to represent the atmospheric transport and 43 chemistry for the members of x, with each tracer sampled at the time and location of all

44 satellite or *in situ* observations. These 'sensitivities' between the simulated mixing ratios and

- 45 the state vector members fill the transport matrix H. In our case, the state vector contains the
- 46 Nord Stream leak emissions for each three-hour window, along with a separate tracer for the
- 47 background CH₄ mixing ratios. All other information is contained in the main text in Section
- 48 3. TOMCAT has previously been used along with this method for the optimisation of
- 49 emissions of CH₄ (McNorton et al., 2018) and halogenated very short lived substances
- 50 (VSLS, Claxton et al. (2020)).

75 Supplementary Figures76

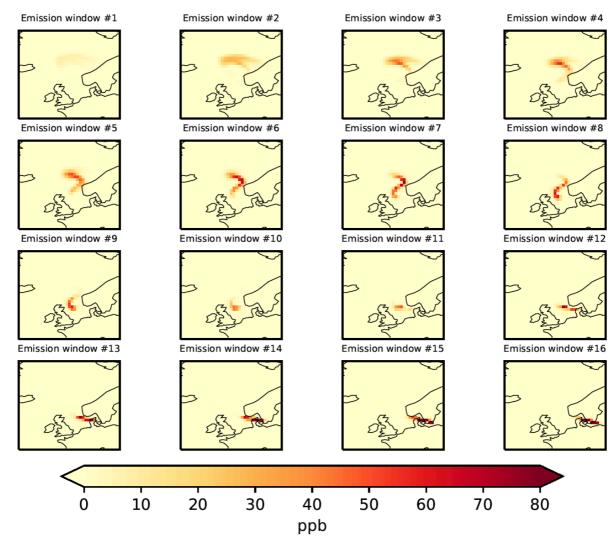

Figure S1: Simulated surface layer CH₄ [ppb] at 9.30am local time on 28th September 2022, for individual 3-hour emission widows over first two days of Nord Stream leaks. Flux from leaks is constant at 4.17 Gg hour⁻¹. Emission window #1 shows the transport of emissions from the first three hours of 26th September 2022, and subsequent panels correspond to subsequent 3-hour time emission windows.

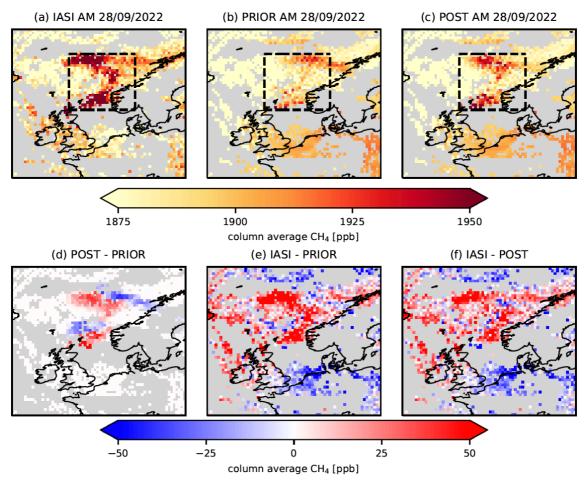

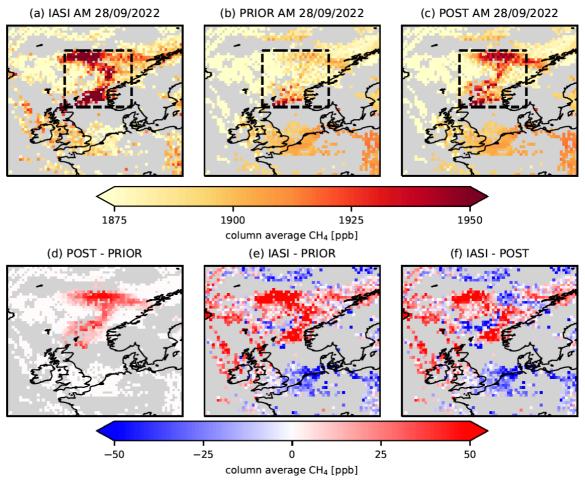

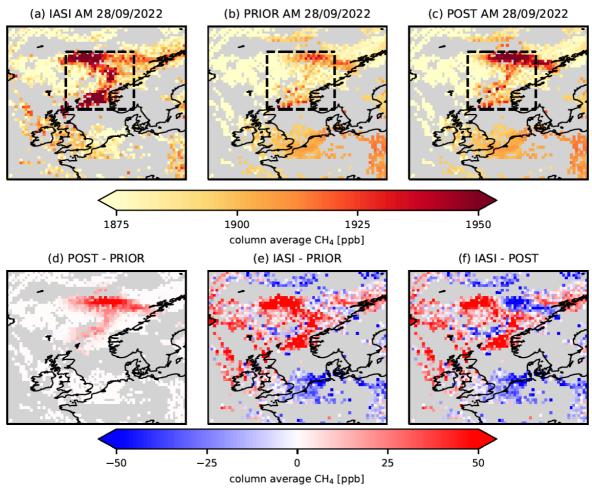

Figure S2: Column average CH₄ (ppb) on the morning of 28th September over the region of the Nord Stream gas leaks from (a) IASI; (b) TOMCAT using the decaying prior emissions; and (c) TOMCAT using the nocorr_1.0_plume posterior emissions based on that prior. Also shown is the difference between the model posterior and prior (d); the difference between IASI and the model prior (e); and the difference between IASI and the model posterior (f). Retrievals and model output are averaged onto $0.25^{\circ} \times 0.25^{\circ}$ grid boxes, weighted inversely to the observations' uncertainties. IASI averaging kernels are applied to the TOMCAT output.

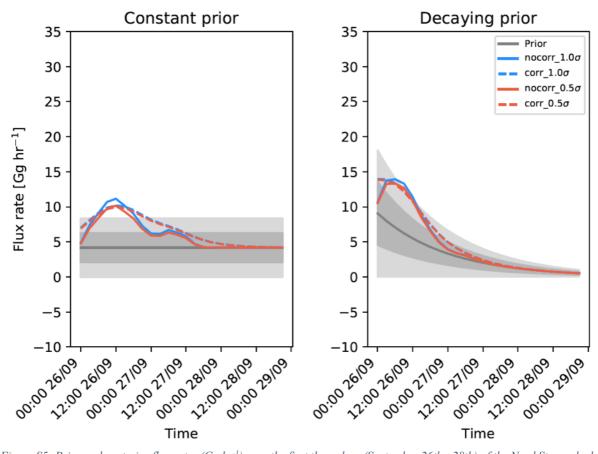

102 103 Figure S3: Column average CH₄ (ppb) on the morning of 28th September over the region of the Nord Stream gas leaks from 103 104 105 106 107 108 (a) IASI; (b) TOMCAT using the constant prior emissions; and (c) TOMCAT using the nocorr_1.0_plume posterior emissions based on that prior for which the regional mean is optimised. Also shown is the difference between the model posterior and prior (d); the difference between IASI and the model prior (e); and the difference between IASI and the model posterior (f). Retrievals and model output are averaged onto $0.25^{\circ} \times 0.25^{\circ}$ grid boxes, weighted inversely to the

observations' uncertainties. IASI averaging kernels are applied to the TOMCAT output.

110 111 112 113 114 Figure S4: Column average CH₄ (ppb) on the morning of 28th September over the region of the Nord Stream gas leaks from (a) IASI; (b) TOMCAT using the decaying prior emissions; and (c) TOMCAT using the nocorr_1.0_plume posterior emissions based on that prior for which the regional mean is optimised. Also shown is the difference between the model posterior and prior (d); the difference between IASI and the model prior (e); and the difference between IASI and the model posterior (f). Retrievals and model output are averaged onto $0.25^{\circ} \times 0.25^{\circ}$ grid boxes, weighted inversely to the observations' uncertainties. IASI averaging kernels are applied to the TOMCAT output.

Figure S5: Prior and posterior flux rates (Gg hr⁻¹) over the first three days (September 26th - 28th) of the Nord Stream leaks based on IASI data from the morning of 28^{th} September 2022. Posterior fluxes represent those when the regional mean in the region highlighted in **Error! Reference source not found.** is optimised rather than the individual retrievals. Prior flux rate is shown in grey, with dark grey shaded region showing the 50% prior uncertainty and the light grey shaded region showing the 100% prior uncertainty. Dashed lines show posterior inversions with prior temporal correlations imposed whilst solid lines show those without prior correlations. Blue lines show inversions with 100% prior uncertainty imposed, whilst red lines show those with 50% prior uncertainty.

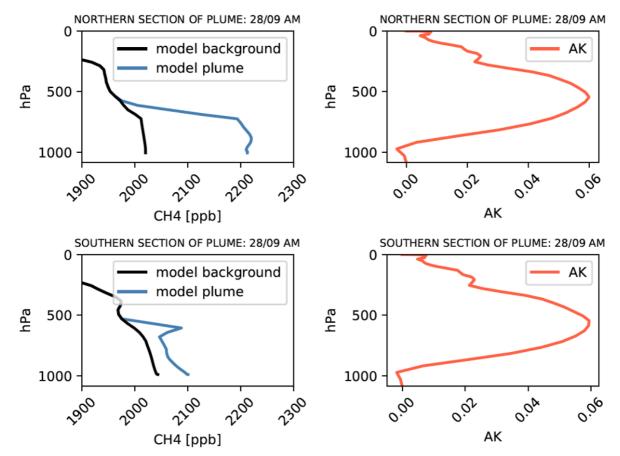

Figure S6: Simulated vertical profiles of CH₄ mixing ratios (ppb) in the northern (top left) and southern (bottom left) sections of the observed plume on the morning of 28th September 2022. Background CH₄ (black) and CH₄ from the Nord Stream leaks (blue) are highlighted separately. Also shown is the mean averaging kernel distribution for the IASI-retrieved column average CH₄ for the northern (top right) and southern (bottom right) sections of the plume.

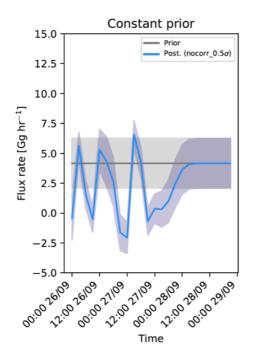

Figure S7: Prior and posterior flux rates (Gg hr⁻¹) over the first three days (September 26th - 28th) of the Nord Stream leaks
based on ICOS data at NOR, BIR and UTO. HTM is excluded do to its proximity to the Nord Stream emission grid cell.
Prior flux rate is shown in grey, with grey shaded region showing the 50% prior uncertainty. Blue line shows posterior
fluxes.

144Table S1: Total flux from Nord Stream leaks (Gg) over the first two days for all inversion scenarios. Uncertainties represent145derived posterior uncertainty from the inversion. For the reported mean values in each column, we allocate the uncertainty146as the largest uncertainty of the individual results instead of propagating the individual uncertainties, which often do not147overlap.

	Constant prior (all data)	Decaying prior (all data)	Constant prior (plume only)	Decaying prior (plume only)	Constant prior (regional mean)	Decaying prior (regional mean)
nocorr_1.0	292 ± 22	224 ± 21	291 ± 23	241 ± 23	342 ± 31	311 ± 31
