11 **Abstract**

12 Winter fog and severe aerosol loading in the boundary layer over north India, especially in the Indo-
13 Gangetic Plain (IGP), disrupts the daily lives of millions of people in the region. To understand better
14 the role of aerosol-radiation feedback on the occurrence, spatial extent, and persistence of winter fog;
15 and the associated aqueous chemistry in fog in the IGP, several model simulations have been
16 performed using the Weather Research and Forecasting model coupled with chemistry (WRF-Chem).
17 While WRF-Chem was able to represent the fog formation for the December 23-24, 2017 fog event
18 over the central IGP in comparison to station and satellite observations, the model underestimated
19 PM_{2.5} concentrations compared to the Central Pollution Control Board of India monitoring network.
20 While evaluating aerosol composition for fog events in IGP, we found that the WRF-Chem aerosol
21 composition was quite different from measurements obtained during the Winter Fog Experiment in
22 Delhi, with secondary aerosols, particularly chloride aerosol fraction being strongly underpredicted
23 (~66.6%). Missing emission sources (e.g., industry and residential burning of cow dung and trash) and
24 aerosol and chemistry processes need to be investigated to improve model-observation agreement. By
25 investigating a fog event on December 23-24, 2017 over central IGP, we found that the aerosol-
26 radiation feedback weakens turbulence, lowers the boundary layer height, and increases PM_{2.5}
27 concentrations and RH within the boundary layer. Factors affecting the feedback include loss of
28 aerosols through deposition of cloud droplets and internal mixing of absorbing and scattering aerosols.
29 Aqueous-phase chemistry increases the PM_{2.5} concentrations, which subsequently affects the aerosol-
30 radiation feedback by both increased mass concentrations and aerosol sizes. With aerosol-radiation
31 interaction and aqueous phase chemistry, fog formation began 1-2 hours earlier and caused a longer
32 fog duration than when these processes were not included in the WRF-Chem simulation. The increase
33 in RH in both the experiments is found to be important for fog formation as it promoted the growth of
34 aerosol size through water uptake, increasing the fog water content over IGP. The results from this

35 study suggest that the aerosol-radiation feedback and secondary aerosol formation play an important
36 role in the air quality and the intensity and lifetime of fog over IGP, yet other feedbacks, such as
37 aerosol-cloud interactions, need to be quantified.

38

39 **1 Introduction**

40 The Indo-Gangetic Plain (IGP; 21°35'-32°28'N latitude. and 73°50'-89°49'E longitude) in the
41 northern part of the Indian subcontinent is one of the most densely populated and heavily polluted
42 regions in South Asia. The rapid population and economic growth in the IGP region over the last
43 decade have increased air pollution over this region. This is evident from the increasing trend in AOD
44 and NO₂ column concentration over India reported in recent studies (Dey and Di Girolamo, 2011;
45 Ghude et al., 2013; Krishna Moorthy et al., 2013), which has slowed and reversed only recently
46 (Sarkar et al., 2019). The high concentration of aerosols along the IGP and their adverse effects on
47 human health and the environment are increasing (Ghude et al., 2016). Consequently, more than 500
48 million people living in the IGP breathe air that exceeds the National Ambient Air Quality Standards
49 (NAAQS), which has reduced the life expectancy of the people (Debnath et al., 2022; Lelieveld et al.,
50 2015). Lelieveld et al., (2015) estimated a very high number of premature deaths (0.716 million per
51 year) linked to aerosols (PM_{2.5}), thus making Southeast Asia one of the largest regions affected by
52 premature mortality globally.

53 One of the major environmental concerns in the IGP is the urban air quality during winter,
54 especially over the mega-cities, e.g., Delhi, located in the north-western part of IGP (Ghude et al.,
55 2020; Jena et al., 2021; Sengupta et al., 2022). Several urban air pollution hotspots along the IGP
56 extend from northwest to east with monthly average PM_{2.5} greater than 200 μgm⁻³ (NAAQS=60μgm⁻³,
57 24 hr average) in the winter season (Bharali et al., 2019; Krishna et al., 2019). IGP is dominated
58 mainly by fine mode particulates, especially over central to eastern IGP, during post-monsoon and
59 winter (Kumar et al., 2018). Biomass burning (agricultural waste burning, domestic heating, etc.) is an
60 important contributor to the observed high PM_{2.5} loading over IGP during these seasons (Kulkarni et
61 al., 2020; Pant et al., 2015; Pawar and Sinha, 2022; Sharma et al., 2010; Yadav et al., 2020). Delhi is
62 affected substantially by the emissions from agricultural waste burning in the north-western states of
63 Punjab and Haryana during the post-monsoon (October-November) season (Badarinath et al., 2009;
64 Jethva et al., 2018; Kumar et al., 2021). Studies showed that PM_{2.5} increased from ~50 μg m⁻³ to as
65 high as 300 μg m⁻³ (Ojha et al., 2020), and AOD reached 0.98 with the presence of absorbing aerosols
66 (Singh et al., 2018) during the peak biomass burning in post-monsoon.

67 IGP experiences fog (both radiation and advection fog) every winter after the passage of the
68 synoptic wind system called the “Western Disturbances”. The majority of fog events in the IGP during
69 December-January are radiation fog (Deshpande et al., 2023; Ghude et al., 2023), formed due to
70 radiative cooling of the surface. The number of low visibility days due to haze/fog formation has been

71 increasing significantly (Ghude et al., 2017; Jenamani, 2007; Singh and Dey, 2012), impacting socio-
72 economic activities, e.g., aviation (Kulkarni et al., 2019). The increase in the intensity and regional
73 extent of fog over IGP is consistent with the increasing trend in aerosol concentration due to
74 increasing anthropogenic emissions (Sarkar et al., 2006; Syed et al., 2012).

75 Several factors control the formation and persistence of fog in the IGP, e.g., stable boundary
76 layer, low temperature, availability of moisture (supplied by the Western Disturbances and irrigation
77 activities), and the aerosol number and composition (Acharja et al., 2022; Dhangar et al., 2021). It has
78 also been suggested that the atmospheric rivers (moisture incursion from Arabian Sea) act as a source
79 of water vapor over IGP, which fuels the intensification of fog and haze (Verma et al., 2022) during
80 winter. The high aerosol concentration in the boundary layer influences fog formation (Gautam et al.,
81 2007; Safai et al., 2019) over the IGP by providing the needed cloud condensation nuclei (CCN) for
82 activation into fog droplets. In addition, aerosols induce surface cooling by reducing solar radiation at
83 the surface while warming the lower troposphere by absorption (Ding et al., 2016; Yu et al., 2002). A
84 reduction in surface-reaching solar radiation by ~19% has been reported during winter over Kanpur in
85 the IGP (Dey and Tripathi, 2007). The reduced solar flux affects the boundary layer stability and
86 depth by suppressing the thermals and thus further increasing the surface aerosol concentration via
87 aerosol-radiation feedback, which is very strong over the IGP (Bharali et al., 2019). Kumar et al.,
88 (2020) have shown that aerosol-radiation feedback significantly improves the accuracy of PM_{2.5} and
89 temperature forecasts in Delhi. Srivastava et al., (2018) reported that the direct aerosol forcing over
90 polluted regions is very large with values up to $-80.0 \pm 7.2 \text{ W m}^{-2}$ over the IGP in the winter season.

91 Aerosol-radiation interaction determines that the aerosol distribution is critical for the evolution
92 of fog (Bodaballa et al., 2022; Steeneveld et al., 2015), while microphysics is important for fog
93 formation and dispersal (Boutle et al., 2018; Maalick et al., 2016). Although the relationship between
94 the aerosol chemical composition and aerosol activation to CCN has not been fully understood yet,
95 studies have found that the chemical composition and mixing state of aerosols affect the
96 hygroscopicity (κ) of aerosols (Bodaballa et al., 2022; Ma et al., 2013; Moore et al., 2012; Zhang et
97 al., 2014a). Fog processes involve a complex interplay between local meteorology, radiation,
98 microphysics, and aerosol chemistry, making it difficult to understand the fog lifecycle (Acharja et al.,
99 2022; Maalick et al., 2016; Zhang et al., 2014b). There is considerable heterogeneity in the spatial and
100 temporal aerosol properties over IGP and the poor estimates of their mixing state. Therefore,
101 prediction of fog by weather models is still challenging with biases in fog's onset and dispersal
102 timings.

103 Previous studies have focussed on the impacts of meteorological conditions, topography, or
104 anthropogenic emissions on the poor air quality and intensification of fog during winter over IGP (e.g.
105 Hakkim et al., 2019). However, studies on the effect of feedback induced by the aerosols on the
106 meteorological conditions and thus on aerosol concentration are very limited over this region, except
107 for a few above-mentioned studies which discuss how the aerosol-radiation feedback favors haze and

108 fog during winter. Moreover, fog can provide a medium for aqueous-phase reactions. While several
109 earlier studies have reported an increase in secondary aerosols during fog over IGP, a sensitivity study
110 examining the impact of fog on aqueous phase chemistry has not yet been done over IGP.

111 In the present work, we aim to find the suitable chemistry/physics as well as the meteorology
112 initial/boundary conditions that lead to improved simulations of fog events in the Weather Research
113 and Forecasting model coupled with chemistry (WRF-Chem; (Fast et al., 2006; Grell et al., 2005;
114 Powers et al., 2017). We also explore the role of aerosol-radiation feedback on fog properties as the
115 high aerosol loadings in northern India can impact the heating rates, temperature inversions, and
116 boundary layer height. The role of aqueous chemistry on fog properties and vice-versa is also
117 investigated.

118

119 **2 Methodology**

120 Fog formed due to radiative cooling at the surface on both 23rd and 24th December 2017 over a
121 widespread region of the IGP (Fig. 1a, b). The fog region is located over an area with high PM_{2.5}
122 anthropogenic emissions (Fig. 1c). The IGP is a large region with varying meteorology and aerosol
123 characteristics, therefore, it is divided into three areas, northwest (NWIGP: latitude-longitude range,
124 27°N-32°N,75°E-79°N), central (CIGP: latitude-longitude range, 25°N-28°N,79°E-83°E), and east
125 (EIGP: latitude-longitude range, 24°N-27°N, 83°E-87°E) which are marked by the black rectangles in
126 Fig.1c. Although biomass burning and anthropogenic emissions dominate throughout the IGP during
127 post-monsoon and winter season, the north-westerly wind system results in the gradient distribution of
128 AOD over this region. The downwind regions, CIGP and EIGP are influenced by the long-range
129 transport from the NWIGP, resulting in high AOD with dominant fine particulates over CIGP and
130 EIGP, especially during post-monsoon and winter (Kedia et al., 2014; Kumar et al., 2018). Therefore,
131 representative stations from each region listed in section 2.2 are considered for the sensitivity
132 analyses.

133

134 **2.1 Modeling**

135 The WRF-Chem model version 4.0.3 is used for this study. Earlier studies have successfully
136 used WRF-Chem to predict fog (Pithani et al., 2019) and in the study of aerosol-radiation feedback on
137 air quality (Kumar et al., 2020; Bharali et al., 2019) and fog (Shao et al., 2023). The model domain is
138 centered at Delhi (77.1°E, 28.7°N) with 300 grid points in the east-west, 170 grid points in the south-
139 north direction (Fig. 1c), and 50 vertical eta levels with the model top at 50 hPa. The horizontal grid
140 spacing of the domain is 10 km, while the vertical grid spacing varies from higher resolution (~200 m)
141 in the boundary layer to coarser resolution (~1200 m) near the model top. We conduct three model
142 configurations (Table 1) for December 20-24, 2017 to identify the best configuration for
143 meteorological simulations. The three experiments have been designed with different combinations of
144 meteorological initial/lateral boundary conditions and planetary boundary layer (PBL) physics.

145 Experiment 1 (EXP1) uses the National Centers for Environmental Predictions (NCEP) Final Analysis
146 (GFS-FNL; $1^\circ \times 1^\circ$, 6 hourly) meteorology data for initial and boundary conditions and the YSU
147 (Yonsei University; (Hong et al., 2006) PBL scheme. Experiments 2 and 3 (EXP2, EXP3) use ERA-
148 Interim Project ($1.125^\circ \times 0.703^\circ$, 6 hourly) for meteorology initial and boundary conditions. EXP2
149 uses the YSU PBL scheme while EXP3 uses the ACM2 (Asymmetric Convective Model version 2)
150 PBL scheme. ACM2, is a hybrid of the original nonlocal closure (Pleim and Chang, 1992) and a local
151 closure eddy diffusion scheme (Pleim, 2007a, 2007b). The YSU PBL option was coupled with the
152 Noah LSM while ACM2 was coupled with Pleim-Xiu LSM. While YSU permits investigations of
153 both aerosol-radiation (AR) and aerosol-cloud interactions, aerosol-cloud interactions are not possible
154 when using the ACM2 PBL scheme because the ACM2 PBL scheme does not provide the exchange
155 coefficient for heat, which is required to calculate the activation fraction for mass and number for each
156 bin/mode. ACM2, on the other hand, has been shown to perform well for air quality in the IGP
157 (Mohan and Gupta, 2018), however, they tested the YSU and ACM2 schemes during the summer time
158 (1-15 June 2010) and focused on the evaluation of temperature, wind speed, PBL height, ozone, and
159 PM_{10} . To ensure that model captures all the relevant meteorological parameters including relative
160 humidity reasonably well during fog in winter, we designed EXP1, EXP2 and EXP3.

161 The advantage of Pleim-Xiu LSM (PX-LSM) is that it allows nudging of soil moisture and
162 temperature to improve the prediction of meteorology near the surface (Pleim and Gilliam, 2009;
163 Pleim and Xiu, 2003; Xiu and Pleim, 2001) which Noah LSM does not include. The PX-LSM
164 includes two-layer soil (0–1 and 1–100 cm) model, canopy moisture, and aerodynamic and stomatal
165 resistance. Ground surface (1 cm) temperature is calculated from the surface energy balance using a
166 force-restore algorithm for heat exchange within the soil. Although the two-layer approach in PX-
167 LSM is less detailed than the multilayer soil models such as the Noah LSM (four soil layers; Chen and
168 Dudhia 2001), it performs well with realistic initialization for soil moisture and through dynamic
169 adjustment in the model simulation where soil moisture is indirectly nudged according to differences
170 in 2-m temperature (T2) and 2-m relative humidity (RH) between the model and observation (Pleim
171 and Xiu, 2003). Soil moisture nudging adjusts the surface evaporation (direct soil surface evaporation,
172 vegetative evapotranspiration, and evaporation from wet canopies) which then affects the partitioning
173 of available surface energy into latent and sensible heat flux and thus reduces errors in T2 and 2-m
174 RH.

175 For EXP2, meteorological initial conditions were refreshed every 24 hours, while EXP3 was a
176 continuous run but soil moisture was nudged to the Era-Interim dataset to improve the prediction of
177 surface fluxes. All other physics and chemistry options are the same for all the experiments except the
178 surface physics option, which changes with the PBL scheme used. The deposition of cloud droplets is
179 an important moisture and aerosol sink during fog events. For all these simulations, the deposition
180 velocity of cloud droplets was reduced to 0.01 m s^{-1} based on Stoke's Law and previous studies
181 (Katata et al., 2015; Tav et al., 2018) because its default value (0.1 m s^{-1}), is large.

182 To examine the radiative effects of aerosols and aqueous phase chemistry additional
183 simulations have been done using the meteorological configuration in EXP3, with aerosol-radiation
184 (wFB) feedback plus aqueous chemistry (wAq.chem), without aerosol-radiation feedback (nFB) but
185 with aqueous chemistry, and without aqueous chemistry (noAq.chem) but with aerosol-radiation
186 feedback. The analysis has been done for the fog events on 23rd and 24th December 2017 as

187 Impact of radiation feedback=Parameters in wFB- Parameters in nFB

188 Impact of aqueous phase chemistry= Parameters in wAq.chem- Parameters in noAq.chem

189 Emissions used in the WRF-Chem simulations are from the EDGAR-HTAP v2 (*Emissions*
190 *Database for Global Atmospheric Research- Hemispheric Transport of Air Pollution; 0.1° x 0.1°*)
191 inventory for anthropogenic emissions and FINN v2.2 (*Fire INventory from NCAR; 1 km x 1 km*) fire
192 emission inventory (Wiedinmyer et al., 2011). Trash-burning emissions (Chaudhary et al., 2021) are
193 also included in the simulations. The model calculates the biogenic emissions online using MEGAN
194 v2.04 (*Model of Emissions of Gases and Aerosols from Nature*) (Guenther et al., 2006). The initial and
195 lateral boundary conditions for chemical constituents are from the global chemistry transport model
196 CAM-Chem (*Community Atmosphere Model with Chemistry*) (Emmons et al., 2020).

197 The MOZART (Model for Ozone and Related chemical Tracers) chemical mechanism
198 (Emmons et al., 2010) is used for gas-phase chemistry, which includes 85 gas-phase species, 39
199 photolysis, and 157 gas-phase reactions. It has been updated to include an explicit treatment of
200 aromatic compounds, HONO, C₂H₂, and isoprene oxidation scheme (Knote et al., 2014). The lumped
201 toluene used by Emmons et al., (2010) has been speciated into benzene, toluene, and lumped isomers
202 of xylenes (Knote et al., 2014). For this study, HCl emissions, transport, dry, and wet deposition are
203 represented. However, HCl gas-phase reaction is not included in MOZART.

204 The Model for Simulating Aerosol Interactions and Chemistry (MOSAIC) with four size bins
205 (0.039–0.156, 0.156–0.625, 0.625–2.500, and 2.5–10.0 μm dry diameters) coupled with MOZART
206 gas-phase chemistry is used (Fast et al., 2006; Zaveri et al., 2008). The bin sizes are defined by their
207 lower and upper dry particle diameters, so there is no transfer of particles between bins during water
208 uptake or loss. It is assumed that aerosols in each bin are internally mixed with the same chemical
209 composition while they are externally mixed in different bins.

210 The aerosol composition includes sulfate (SO₄²⁻), ammonium (NH₄⁺), nitrate (NO₃⁻), aerosol
211 water, sea salt (Na⁺, Cl⁻), methanesulfonate (CH₃SO₃⁻), carbonate (CO₃²⁻), calcium (Ca⁺), black carbon
212 (BC), organic mass (OC), and unspecified inorganic species such as silica, inert minerals, and trace
213 metals lumped together as other inorganic mass (OIN). For OC, primary OC and secondary OC are
214 represented separately, where the latter is simulated using the volatility basis set (VBS) approach.
215 Reactive inorganic species such as potassium (K⁺) and magnesium (Mg⁺) are usually present in much
216 smaller amounts and are equivalent to Na⁺ since their sulfate, nitrate, and chloride salts are similar in
217 terms of their solubility in water.

218 MOSAIC treats condensation and evaporation of trace gases to/from particles, nucleation
219 (new particle formation), and coagulation. Aerosol coagulation (Brownian) is based on (Jacobson et
220 al., 1994) and nucleation is based on (Wexler et al., 1994) parameterization of H₂SO₄-H₂O
221 homogeneous nucleation. Sulfate, nitrate, chloride, and ammonium aerosols are mainly formed
222 through oxidation and neutralization/condensation of gas precursors. Gas-phase sulfuric acid (H₂SO₄)
223 is produced by the gas-phase oxidation of SO₂ by OH and nitric acid (HNO₃) formation is via the
224 oxidation of NO₂ by OH. HCl is a primary emission product. The neutralization/condensation of
225 H₂SO₄, HCl, and HNO₃ with NH₃ produces ammonium such as ammonium sulfate (NH₄)₂SO₄,
226 ammonium bisulfate (NH₄HSO₄), ammonium chloride (NH₄Cl) and ammonium nitrate (NH₄NO₃),
227 respectively. The thermodynamic modules in MOSAIC for the dynamic gas-particle partitioning of
228 aerosols MTEM (Multicomponent Taylor Expansion Method) and MESA (Multicomponent
229 Equilibrium Solver for Aerosols) calculate the activity coefficient in aqueous phase aerosols and
230 compute the intraparticle solid-liquid phase equilibrium respectively (Zaveri et al., 2005, 2008). The
231 Adaptive Step Time-split Euler Method (ASTEM) coupled with MESA-MTEM dynamically
232 integrates the mass transfer equations.

233 Aqueous-phase chemistry uses a bulk water approach employing the Fahey and Pandis (2001)
234 mechanism. It calculates sulfate formation, formaldehyde oxidation, and non-reactive uptake of nitric
235 acid, hydrochloric acid, ammonia, and other trace gases (Chapman et al., 2009; Pye et al., 2020).
236 Aqueous-phase sulfate is produced via oxidation of SO₂ by H₂O₂, O₃, TMI (Transition metal Ion:
237 Fe(III), Mn(II)) catalyzed O₂ and NO₂. TMI concentrations are prescribed in the model to 0.01 μg m⁻³
238 for Fe(III) and 0.005 μg m⁻³ for Mn(II) (Martin and Good, 1991). The Fe(III) values are within the
239 range of water soluble iron in winter time aerosol reported in India (Kumar and Sarin, 2010). Wet
240 removal (scavenging), is represented by the (Neu and Prather, 2012) scheme for trace gases and Easter
241 et al., (2004) for aerosols.

242

243 **2.2 Observations**

244 To evaluate the model output, observations of aerosols and meteorology have been obtained
245 from several satellites as well as ground-based measurement platforms. To examine the aerosol
246 loading and spatial and temporal distribution, daily Level 2 Aerosol Optical Depth (AOD) retrievals
247 from the Moderate Resolution Imaging Spectroradiometer (MODIS) aboard Terra and Aqua satellites
248 are obtained at the spatial resolution of 10 km x 10 km (at nadir) pixel array. It provides aerosol
249 properties from the Dark Target (DT) algorithm applied over the ocean and dark land (e.g.,
250 vegetation) and Deep Blue (DB) algorithms over the entire land areas, including both dark and bright
251 surfaces. Each MOD04_L2 (Terra) / MYD04_L2 (Aqua) products are available at a 5-minute time
252 interval with an output grid of 135 pixels in width by 203 pixels in length.

253 The Indian National Satellites (INSAT-3D) in the geostationary orbit at inclinations of 82°
254 longitude provide an imager fog product (3DIMG_L2C_FOG) with a spatial resolution of 4 km every
255 30 min (www.mosdac.gov.in). For daytime, the visible channel observation is used to detect fog,
256 whereas thermal infrared is used to reduce false alarms such as medium/high clouds and snow areas.
257 INSAT 3D's 'day microphysics' data component analyzes solar reflectance at three wavelengths: 0.5
258 μm (visible), 1.6 μm (shortwave infrared), and 10.8 μm (thermal infrared). Night-time fog is derived
259 from TIR-1 (12.0 μm and 10.0 μm) and MIR (10.8 μm and 3.9 μm) channel brightness temperature
260 over the Indian region. INSAT-3D provides fog intensity varying from 1 to 4 indicating SHALLOW
261 for visibility > 600 m; MODERATE, DENSE, and VERY_DENSE, respectively for visibility varying
262 from 0 to 500 m (Banerjee and Padmakumari, 2020). If the visibility is greater than 700 m it indicates
263 no fog while visibility > 1000 m represents very clear skies. Validation of INSAT-3D fog products
264 over the IGP shows a 66%-68% probability of detection and a 10% false alarm rate. It also captures
265 the entire life cycle of fog from formation to dissipation. However, detecting fog during multilayer
266 clouds is still challenging with INSAT-3D (Arun et al., 2018; Chaurasia and Gohil, 2015; Chaurasia
267 and Jenamani, 2017).

268 Ground-based monitoring sites provide hourly data of relative humidity, surface temperature,
269 and wind speed measured by the Central Pollution Control Board, CPCB (<http://cpcb.nic.in>). Given
270 the data availability from CPCB stations, nine stations have been considered representing each region
271 of IGP, which include, Amritsar, IGI Airport (Indira Gandhi International Airport, Delhi), IHBAS
272 (Delhi), Dwarka (Delhi), RKP (Delhi) in the North-West IGP; Kanpur, Lucknow in Central IGP and
273 Patna, Muzaffarpur in East IGP.

274 In addition, measurements of several aerosols, trace gases, and meteorology at Delhi (IGI
275 Airport) from the Winter Fog Experiment (WiFEX) for the period December 10-31, 2017, have also
276 been used to validate the model output. The WiFEX, an initiative of the Ministry of Earth Sciences
277 (MoES), India, is a ground-based measurement campaign at the IGI Airport Delhi to understand fog's
278 physical and chemical features. Additional details of the WiFEX project and related publications can
279 be found in Ghude et al., (2017).

280

281 **3 Meteorology Evaluation**

282 Previous studies simulating fog highlight the importance of high model vertical resolution
283 (Pithani et al., 2019; Van Der Velde et al., 2010) for representing the fog formation and the growth of
284 the fog layer, model initialization (Yadav et al., 2022), initial relative humidity (Bergot and Guedalia,
285 1994; Pithani et al., 2020), and PBL schemes (Chen et al., 2020; Pithani et al., 2019). In the present
286 study, 2-m relative humidity (RH2), 2-m temperature (T2), and 10-m wind speed (WS) from WRF-
287 Chem have been evaluated using ground-based measurements from CPCB monitoring network and
288 WIFEX campaign for nine stations across the IGP. The comparison of WRF-Chem results with
289 observations shows that RH2 and T2 are sensitive to the choice of the meteorological initial and

290 boundary conditions as illustrated by six stations in major cities (Fig. S1). WRF-Chem compares
291 better with the observations for simulations driven by the ERA-Interim reanalysis than with GFS-FNL
292 reanalysis since ERA-Interim provides more realistic RH2 than GFS-FNL (Figs. S2 a-f). For example,
293 RH2 from EXP1 (GFS) varies from 10 to 50%, while RH2 from EXP2 and EXP3 varies from 30 to
294 100%, which is closer to observation, especially for NWIGP and CIGP. For EIGP, RH2 from EXP1
295 (GFS) compares better than ERA-Interim, which overestimates the observed RH2. ERA-Interim and
296 YSU PBL scheme showed damping of RH2 continuously increasing the bias in RH2 with time (not
297 shown), which was corrected in EXP2 by refreshing meteorology every day at 00h UT during the
298 model simulation. In addition, maps of surface RH2 and T2 (Figs. S2 g-j) show that the GFS-FNL
299 dataset has lower relative humidity throughout the domain as compared to ERA-Interim. There are
300 differences in simulated 2-m temperature between these two datasets which are of smaller relative
301 magnitude compared to the RH2.

302 The GFS-FNL driven meteorology EXP1 has a warm bias in NWIGP and CIGP, especially during
303 night-time, while over EIGP, the model prediction agrees well with observations. EXP2 with the
304 ERA-Interim driven meteorology and YSU PBL scheme also shows good agreement between
305 modeled and observed T2 in EIGP. The ERA-Interim driven meteorology with the ACM2 PBL
306 scheme in EXP3 has a cold bias of up to 7°C over EIGP during daytime from 22nd to 24th December.
307 The wind speed evaluation shows that WRF-Chem is over-predicting wind speed. However, it is also
308 possible that some CPCB stations (e.g., Amritsar and RK Puram) have a wind speed low bias due to
309 the low measurement height and obstructions such as tall trees near the monitoring station as shown in
310 FigS3. WRF-chem in general overestimates wind speed and several earlier studies have reported this
311 bias in wind speed (e.g., Mohan and Gupta 2018; Pithani et al.,2019). Moreover, WRF-Chem does not
312 have the capability to represent building meteorology and parameterizes the effects of urban areas on
313 meteorology through roughness length, which likely leads to overestimation of wind speed. Note that
314 at other sites (e.g., over IGI-Delhi and Kanpur) the model measurement agreement is better.

315 The WRF-Chem performance has been statistically assessed against observation using the
316 Taylor Diagram (Taylor, 2001), which provides a statistical summary of how well the model output
317 agrees with the observation in terms of the Pearson correlation, their centered root-mean-square error
318 (RMSE) difference, and the ratios of their variances (Fig. 2).

319 The centered RMS difference, the correlation, and the standard deviation are related by the following
320 formula:

$$321 E'^2 = \sigma_o^2 + \sigma_m^2 - 2\sigma_o\sigma_m R$$

322 where R is the correlation coefficient between the model-simulated and observed fields, E' is the
323 centered RMS difference between the fields, and σ_m^2 and σ_o^2 are the variances of the model-simulated
324 and observed fields, respectively. The correlation(R), centered RMS difference (E') and standard
325 deviations of the model simulated and observed fields are calculated by the following formulas:

326
$$R = \frac{\frac{1}{N} \sum (M_n - \bar{M})(O_n - \bar{O})}{\sigma_m \sigma_o} \quad (1)$$

327
$$E'^2 = \frac{1}{N} \sum [(M_n - \bar{M}) - (O_n - \bar{O})]^2 \quad (2)$$

328
$$\sigma_m^2 = \frac{1}{N} \sum (M_n - \bar{M})^2 \quad (3)$$

329
$$\sigma_o^2 = \frac{1}{N} \sum (O_n - \bar{O})^2 \quad (4)$$

330 where the overall mean of a field is indicated by an overbar.

331 The percentage bias has also been included to further evaluate the WRF-Chem results. In Fig.
 332 2, better agreement of WRF-Chem results with observations are shown by the marker's proximity to
 333 the "OBS" dashed black line. The WRF-Chem RH has a good correlation for all three experiments
 334 with $r > 0.75$ at all the locations in IGP for all the experiments. However, the RMSE (shown by red
 335 dashed contours) and the standard deviations are larger for the EXP1. The relative bias is also large
 336 ($>20\%$) for EXP1 (GFS-FNL) compared to EXP2 and EXP3 which lie closer to the dashed black line
 337 indicating that the simulated RH variations are similar to observations. For all the experiments, WRF-
 338 Chem T2 agrees well with observations with a correlation between 0.8 and 0.95. The points are
 339 concentrated near the dashed line showing a low RMSE and standard deviation for T2, signifying a
 340 good agreement of simulated T2 with observation in terms of temporal variation but the T2 relative
 341 bias is large for EXP1 ($>20\%$). The RMSE and relative bias for EXP1 are larger for several of the
 342 stations. The temporal variability of T2 and RH is predicted well for all the combinations of inputs
 343 (Fig. S1), however, the accuracy of simulated T2 and RH is sensitive to the choice of meteorological
 344 initial/boundary conditions. WRF-Chem predicted RH and T2 agree better with observations when
 345 initialized with ERA-Interim meteorology than with GFS-FNL.

346 The WRF-Chem runs driven by ERA-Interim with YSU (EXP2) and ACM2 PBL (EXP3)
 347 schemes predicted the surface meteorology better over the IGP than the WRF-Chem run driven by
 348 GFS (EXP1). By examining the modeled cloud water content in the lowest model level with the
 349 INSAT-3D satellite fog intensity for the 23rd and 24th December 2017 (Fig. 3), it is apparent that
 350 WRF-Chem with the ACM2 PBL scheme compared qualitatively well with observations obtained
 351 from INSAT-3D satellite in terms of fog coverage over CIGP, while the WRF-Chem run with the
 352 YSU PBL scheme did not produce widespread fog. However, there is also fog over EIGP in WRF-
 353 Chem with the ACM2 PBL scheme although it is not observed by the satellite. This is because the
 354 model has a cold bias in T2 and a high surface RH over East IGP with ACM2 PBL and Pleim-Xiu
 355 surface scheme as discussed earlier, which favors the formation of fog in this region. The time series
 356 in Fig. 4 shows that EXP3 is capable of predicting the duration of fog on 23rd and 24th December.
 357 There is a data gap from INSAT 3D observations because it is unable to capture fog during daytime in
 358 the presence of mid and high-level clouds.

359 In conclusion, EXP3 is the best configuration for predicting fog formation where the ERA-
 360 Interim meteorology, the ACM2 PBL and surface schemes, and soil moisture nudging is used in the

361 WRF-Chem simulation. Therefore, the evaluation of predicting AOD, surface aerosol concentrations,
362 and aerosol composition as well as analysis of the impact of aerosols on fog formation uses the EXP3
363 configuration.

364

365 **4 Aerosol Evaluation**

366 Aerosol is an important factor in correct prediction of fog (Maalick et al., 2016; Stolaki et al.,
367 2015) as the number of fog droplets depends on the aerosol size distribution and concentration.
368 Aerosols as CCN can affect the liquid water content in fog and therefore an increase in aerosol
369 concentration can significantly affect fog lifetime (Stolaki et al., 2015; Zhang et al., 2014b). AOD
370 retrievals from the MODIS satellite have been used to validate the modeled AOD (Fig. 5). It is
371 observed that the model captures several important features of the MODIS retrieved AOD spatial
372 distribution but at the same time somewhat struggles to reproduce the observed AOD magnitude in
373 some parts of the domain. One possible reason for the underestimation would be the EDGAR-HTAP
374 emission inventory, which has a low bias for residential sector PM_{2.5} emissions in India (Sharma et al.,
375 2022). For instance, the model successfully predicts high aerosol loading seen by MODIS on 20 and
376 21 December over CIGP and EIGP. This is the region with dense fog both in model and observation.
377 Higher AOD (>0.5) over CIGP and EIGP can be attributed to the accumulation of aerosols that are
378 transported by north-westerly winds to these regions from NWIGP (Dey and Di Girolamo, 2011; Jain
379 et al., 2020; Jethva et al., 2018; Kumar et al., 2018; Yadav et al., 2020). However, WRF-Chem
380 underestimates AOD over the NWIGP (AOD<0.3) throughout the simulation period and during 23-24
381 December over CIGP and EIGP where the latter may be related to enhanced scavenging of aerosols by
382 fog droplets.

383 The west to east gradient in aerosol loading over IGP is consistent with surface PM_{2.5}
384 distribution (Fig. 6a). Surface PM_{2.5} concentration is highest in EIGP (>100 µg/m³) and it decreases
385 gradually towards NWIGP (~60-80 µg/m³). The time series of PM_{2.5} from CPCB measurements and
386 the model at stations representative of each region in IGP shows that simulated PM_{2.5} compares well
387 with observation in terms of day-to-day variation over most of the locations in the IGP (Fig. 6 b-e).
388 The comparison is good over Amritsar (an NWIGP location), where PM_{2.5} is mostly primary aerosols
389 from local emissions e.g., residential heating related biomass burning. Agricultural waste burning is at
390 its peak during post monsoon months (Oct-Nov), whereas during winter burning for residential
391 heating increases and the stable boundary layer confines these emissions near the surface (Kumar et
392 al., 2021; Pawar and Sinha, 2022). PM_{2.5} at Amritsar shows a bimodal distribution with morning and
393 evening peaks whereas it is absent in the model likely due to the absence of diurnal variations in the
394 WRF-Chem anthropogenic emissions.

395 A statistical analysis (Table S1) shows a minimum mean bias for PM_{2.5} at Amritsar (-2.2%) while in
396 other stations it ranges from 48 to 53% similar to the reported range of model bias (underestimated by
397 40–60%) in winter over IGP by earlier studies (Bran and Srivastava, 2017; Ojha et al., 2020). RMSE

398 values range from 41 to 138 $\mu\text{g}/\text{m}^3$ (normalized RMSE~0.4 to 0.7) comparable to the reported values
399 by these studies. The Pearson correlation coefficient (r) for the simulated and observed day-to-day
400 variation in $\text{PM}_{2.5}$ lies between 0.4 and 0.7 for all the stations in Fig. 6 except at Patna which lies
401 within the range in these studies. Poor correlation at Patna is due to the loss of $\text{PM}_{2.5}$ during fog in the
402 model as discussed earlier.

403 At Delhi, the daily variations are predicted well although WRF-Chem underestimates $\text{PM}_{2.5}$
404 observations during the first 4 days. Delhi experiences severe air pollution and haze with high PM
405 loading ($> 500 \mu\text{g m}^{-3}$) (Bharali et al., 2019). The model is successful in predicting the high $\text{PM}_{2.5}$
406 episode on the 24th of December, but WRF-Chem underpredicts the SO_4^{2-} , NH_4^+ , NO_3^- and Cl^-
407 concentrations (Fig. 7). Although simulated SO_2 and NH_3 are comparable with observation, sulfate,
408 and ammonium are underestimated in the model. SO_4^{2-} is underestimated by $\sim 9 \mu\text{g m}^{-3}$, while NH_4^+ ,
409 NO_3^- and Cl^- are underestimated by $\sim 30 \mu\text{g m}^{-3}$, $\sim 19 \mu\text{g}/\text{m}^3$ and $\sim 40 \mu\text{g}/\text{m}^3$ on average, respectively. In
410 addition, the WRF-Chem model results show that a large percentage of $\text{PM}_{2.5}$ is classified as “other
411 inorganics”, which is usually dominated by $\text{PM}_{2.5}$ other than BC and OC. This leads to the
412 underestimation of $\text{PM}_{2.5}$ over Delhi. Studies report very high chloride over the IGP with values
413 exceeding $100 \mu\text{g m}^{-3}$ (Lalchandani et al., 2021) during winter emitted from increased trash burning
414 and industrial emissions (Pant et al., 2015; Patil et al., 2013). WRFChem incorporates trash-burning
415 emissions which include HCl emissions from Chaudhury et al., (2021) for this study however, the
416 inventory contains annual emissions and fails to resolve the seasonality of trash-burning emissions as
417 identified by Nagpure et al., (2015). They suggested almost all the waste-burning emissions in
418 neighbourhoods with higher socioeconomic status in Delhi occur due to the use of waste as cheap
419 heating fuel by individuals such as night watchmen and pavement dwellers. Chaudhary et al., (2021)
420 considers waste burning that occurs due to lack of collection infrastructure, and at landfills and,
421 therefore, shows a concentration of waste burning emissions around the periphery of Delhi but low
422 waste burning emissions in the relatively prosperous city centre. In addition, emissions from other
423 sources (e.g., industries) are unaccounted for in the model which likely leads to the underestimation in
424 modeled chloride.

425 Over the CIGP and EIGP, the underestimation in $\text{PM}_{2.5}$ is mostly observed at the east IGP
426 locations during the dense fog. It is well known that the hygroscopic aerosols grow in size and are
427 deposited to the surface during fog (Gupta and Mandariya, 2013; Kaul et al., 2011). $\text{PM}_{2.5}$ shows an
428 increase initially with the onset of fog and then it decreases as the aerosols grow and get deposited
429 through fog droplets. A two order higher deposition rate (Fig. 6 f, g) during fog compared to the
430 deposition rate of dry aerosol results in the lower $\text{PM}_{2.5}$ over CIGP and EICP during fog events.

431 Previous studies have reported that models tend to underestimate the AOD observation (David
432 et al., 2018; Pan et al., 2015) during the post-monsoon and winter when agricultural waste burning and
433 anthropogenic emissions dominate. While anthropogenic emissions include a contribution from the
434 residential sector, the emissions from small-scale burning for residential heating over IGP especially

435 during winter are likely underestimated in the current emission inventory (Sharma et al., 2022). This
436 leads to an underestimation of aerosol concentration in the model. Other possible causes for the
437 underestimation are the biases in the simulated meteorology (Govardhan et al., 2015; Kumar et al.,
438 2015; Pan et al., 2015) which affects the aerosol concentration. We corrected some of the biases in
439 meteorology as discussed earlier however there are still residual biases in the simulated meteorology
440 e.g., overestimation of wind speed by WRF-Chem. We also observe underestimation of secondary
441 aerosols over NWIGP which contribute significantly to the aerosol loading over IGP. Secondary
442 aerosol formation is substantial over CIGP and EIGP in the model compared to NWIGP which will be
443 discussed in a later section. The underestimation of $PM_{2.5}$ could also be linked to the uncertainty in the
444 model's chemistry scheme to simulate the secondary aerosols due to missing chemical processes or
445 due to underestimation of sulfur oxidation at different RH levels (Acharja et al., 2022; Pawar et al.,
446 2023; Ruan et al., 2022) . Moreover, several modeling studies have shown significant improvements
447 in forecasting surface $PM_{2.5}$ by assimilation of satellite AOD and $PM_{2.5}$ (Ghude et al., 2020; Jena et al.,
448 2020; Kumar et al., 2020) suggesting the importance of correct initialization of the model in
449 simulating aerosols over IGP.

450

451 **5 Effect of Aerosol Radiation feedback**

452 Interactions of aerosols with radiation affects temperature and surface heat fluxes, thereby
453 weakening the turbulence in the PBL and stabilizing the boundary layer height (Fig. 8b) compared to
454 the clean environment (Fig. 8a). In the presence of well mixed aerosols within the PBL, the radiative
455 effect of aerosols lowers the noontime PBL height (Fig. 8b). However, the presence of absorbing
456 aerosols in the PBL warms the air and changes the thermodynamics. Three cases are shown in Fig.
457 8(c-e) where increases of scattering aerosol concentrations at the top of PBL (Fig. 8c) increases
458 scattering of radiation by the aerosol layer and reduces the surface reaching solar radiation similar to
459 Fig. 8b. Higher concentrations of absorbing aerosols at the top of PBL (Fig. 8d) warms the air above
460 the boundary layer and strengthens the capping inversion stabilizing the PBL and suppressing its
461 growth. The shallow PBL and weakened daytime vertical mixing confines aerosols and water vapor
462 near the surface and worsens the air quality of a region. The aerosols trapped in the stagnant PBL
463 further affects the radiation flux at the surface and creates a positive feedback loop wherein the PBL is
464 continually suppressed until interrupted by some synoptic weather phenomenon, such as the western
465 disturbances in the IGP. On the other hand, higher concentration of absorbing aerosols within the PBL
466 (Fig. 8e) warms the air in the PBL and this results in the higher PBL height. The raised PBL decreases
467 the aerosol concentration near the surface which is termed as a negative feedback effect.

468 The aerosol radiation feedback can affect shortwave heating rates (SWHR). The high aerosol
469 loading over the IGP (Fig. 6 and Fig. 7) allows the AR feedback to reduce the PBL height by more
470 than 140 m throughout the IGP compared to the surrounding region with AR feedback (Fig. 9a). The
471 difference in PBL height with and without aerosol radiation feedback is largest during noontime. The

472 suppressed PBL is due to the decrease in the surface heating flux and the consequent weakening of
473 turbulence in the PBL. The surface solar radiation flux (SWF) decreases by 5-35 % while the surface
474 latent heat (LH) and sensible heat (HFX) fluxes decrease by 5-35 % and 10-60 %, respectively (Fig.
475 S3). The stable, shallow PBL reduces the vertical mixing of aerosols and moisture and confines them
476 near the surface, resulting in increased $PM_{2.5}$ concentrations and RH near the surface with AR
477 feedback (Fig. 9). Although T2 should decrease with the reduction in surface SWF, T2 shows mixed
478 signals with both cooling and warming over IGP. While surface cooling is observed over NWIGP and
479 EIGP, T2 increases with AR feedback over most of CIGP. The response of AR feedback to T2 varies
480 in these three regions probably due to differences in the distribution and types of aerosols and the
481 presence of fog. Increase in surface concentration of $PM_{2.5}$ occurs more over NWIGP and EIGP with
482 increase in BC and OIN over NWIGP, and sulfate aerosol over EIGP which results in the surface
483 cooling due to positive AR feedback in these two regions. Over the CIGP, the AR feedback causes a
484 depletion of surface $PM_{2.5}$ (Fig. 9d), which is likely due to their hygroscopic growth, and then dry
485 deposition (average dry deposition flux of $PM_{2.5}$ =331 $\mu\text{g}/\text{m}^2/\text{hr}$ with AR feedback and 282 $\mu\text{g}/\text{m}^2/\text{hr}$
486 without AR feedback) in dense fog. The increase in RH with AR feedback favours the growth of
487 aerosols in size by the uptake of water

488 Examining further, the time variation of the changes in PBL height, T2, and RH between the
489 simulations with and without aerosol-radiation feedback (Fig. 9g) shows an increase in T2 while the
490 surface fluxes, sensible heat flux, latent heat flux, and downward shortwave radiation flux decrease
491 over CIGP (Fig. 9h). AR feedback affects mostly the lower atmosphere at multiple levels; however,
492 our finding suggests that the decreased shortwave radiation flux decreases the surface fluxes and thus
493 the turbulence in the boundary layer resulting in a reduced PBL height on both days. Figure 9 g and h
494 clearly show a decrease in HFX and LH following the decrease in SWF. Moreover, we observe that
495 the PBL height is sensitive to latent heat flux likely due to its strong dependence on moisture
496 availability (Xiu and Pleim, 2001; Zhang and Anthes, 1982).

497 The impact of AR feedback on T2 depends on factors such as the presence of absorbing
498 aerosols and their vertical distribution via heating or increased SWF (as observed in CIGP, Fig. S4).
499 Absorbing aerosols in WRF-Chem include BC and OIN (other inorganic aerosols), which both
500 increase near the surface (Fig. 9e, Fig. S5) due to their confinement in the stable PBL. Some areas in
501 the fog-affected region show a decrease in BC as well as SO_4^{2-} likely due to increased dry deposition
502 in fog water as discussed earlier in this section for $PM_{2.5}$. As a result, AR feedback changes the
503 absorbing to scattering ratio of aerosols over IGP indicated by the decrease in SSA (Single Scattering
504 Albedo; Fig. S6). In EIGP, sulfate concentrations is larger with AR feedback than without AR
505 feedback with time periods where the difference is $>1 \mu\text{g}/\text{m}^3$ (Fig.11). The BC concentration changes
506 are small ($<0.5 \mu\text{g}/\text{m}^3$) in the EIGP, resulting in a higher SSA near the surface with AR feedback in
507 EIGP. In the CIGP, BC concentrations increase while sulfate aerosols decrease within the PBL with
508 AR feedback (Fig.11) compared to the simulation without AR feedback. A decrease in SSA is seen for

509 the CIGP throughout the boundary layer while in EIGP the decrease occurs near the top of the PBL;
510 difference in SSA due to AR feedback is negligible in NWIGP. Also contributing to the higher SSA in
511 EIGP is the increase in RH (Fig. 9) due to AR feedback favoring the growth of aerosols in size by
512 uptake of water and the production of secondary aerosols such as SO_4^{2-} and NH_4^+ .

513 A similar observation has been made by Ramachandran et al., (2020) where SSA decreases
514 with increasing altitude due to absorbing carbonaceous aerosols at higher elevations which contributes
515 $\geq 75\%$ to the aerosol absorption over IGP. Increased shortwave heating (Fig. 10) is probably caused by
516 the increased absorbing aerosols near the surface which overwhelms the surface cooling due to
517 reduced shortwave radiation at the surface.

518 The increase in 2-m RH is substantial over CIGP on 24th December (Fig. 9g) compared to the
519 previous day following the decrease in PBL height which constrains the moisture near the surface.
520 The decrease in RH by 2% or more when aerosol-radiation feedback is included compared to no
521 aerosol-radiation feedback is likely due to increase in T2. However, the increase in RH in the
522 afternoon associated with a decrease in LH and PBL height is important for the air to saturate which
523 then favors the formation of fog in a polluted environment. Note that the increase in T2 with AR
524 feedback is very small ($< 0.5^\circ\text{C}$) which reduces further after noon ($\sim 12:30$ pm IST) on both days.

525 Another important factor that can affect the extent of change in PBL height is the distribution
526 of aerosols in the vertical (illustrated in Fig. 8). The pressure-time cross-sections of differences in T,
527 $\text{PM}_{2.5}$, BC, and SO_4^{2-} between aerosol radiation (AR) feedback (wFB) and no aerosol radiation
528 feedback (nFB) for three regions, NWIGP, CIGP, and EIGP are shown in Fig. 11. The difference in
529 the PBL height reaches a maximum with the AR feedback during midday (12:30-15:30 IST). Increase
530 in temperature in the boundary layer is observed with AR feedback particularly at the upper PBL in all
531 the regions of IGP. This induces a temperature inversion resulting in a stable and suppressed PBL. In
532 all the regions the decrease in PBL height (100-200 m) is larger on 24th December compared to 23rd
533 December. The difference in the PBL height on 23rd and 24th December with AR feedback on these
534 days is possibly controlled by the aerosol distribution during the previous day or early morning on the
535 same day. For example, in all the regions an increase in $\text{PM}_{2.5}$ is observed the previous night (23:30
536 onwards) till $\sim 11:30$ of December 24, with increased BC over NWIGP and CIGP whereas both BC
537 and SO_4^{2-} over EIGP. The increased $\text{PM}_{2.5}$ concentrations suppress the development of the PBL after
538 sunrise with AR feedback on December 24 compared to that on December 23, leading to the observed
539 differences in ΔPBL height on these two days. Increase in BC concentrations in NWIGP and CIGP are
540 found above the PBL on 24th December whereas BC concentrations decrease within the PBL. This BC
541 concentration gradient creates a temperature inversion, for example between 10:30-14:30 IST. The
542 increase in BC warms the air in the PBL; however, the warming is not strong enough to cause
543 negative feedback over CIGP. On 23rd December a small increase in BC is uniform throughout the
544 PBL, while there is a decrease in SO_4^{2-} concentrations, resulting in a warmer PBL (Fig. 11) with AR
545 feedback.

546 In EIGP, BC distribution is similar to that in CIGP with AR feedback while there is a
547 substantial increase in sulfate aerosol in the PBL. This results in the strongest extinction in EIGP as
548 evident from the largest difference in PBL height and surface cooling with AR feedback among the
549 three regions. Although Δ PBL is small on 23rd December, it still results in the accumulation of
550 aerosols during night-time (~23:30 pm onwards) which further strengthens the AR feedback effect the
551 next day in NWIGP and CIGP. Thus, AR feedback stabilizes the PBL, increases PM_{2.5} and RH in the
552 PBL making conditions favourable for persistence of fog over IGP.

553

554 **6 Effect of Aqueous phase chemistry**

555 In this section we discuss the impact of aqueous phase chemistry on aerosol composition and
556 its interaction with meteorology. There is a considerable difference in the surface concentration of
557 PM_{2.5} (>16 $\mu\text{g m}^{-3}$) in the absence of aqueous chemistry over CIGP and EIGP where fog occurs (Fig.
558 12a) while the difference is negligible over NWIGP where fog does not occur. This is due to the
559 formation of secondary aerosols through aqueous phase chemistry and the hygroscopic growth of
560 aerosols during fog in these regions with the inclusion of aqueous chemistry in the model. In the
561 region between CIGP and EIGP (83E-84E; marked by the box in Fig. 12a), PM_{2.5} concentration is less
562 in the simulation with aqueous-phase chemistry than without aqueous-phase chemistry because
563 deposition of fog water aerosols to the surface increases as the fog thickens (Fig. 13, Fig. S7). Figure
564 13 shows the relation between formation of secondary aerosols, deposition flux of PM_{2.5}, and fog with
565 and without aqueous phase chemistry. During the fog event, the secondary aerosols (SO_4^{2-} , NH_4^+)
566 increase significantly by 4-10 $\mu\text{g m}^{-3}$ due to aqueous phase chemistry adding to the PM_{2.5} burden over
567 IGP. The intensity of fog is high around midnight December 24-25 compared to that on 23rd and 24th
568 (1:30-11:30 IST)) which increases the dry deposition flux of PM_{2.5} causing a sharp drop in the PM_{2.5}
569 concentration on 24th December compared to the previous night's fog event. The observed change in
570 PM_{2.5} over a region is the net result of the formation of secondary aerosols and its deposition with fog
571 droplets.

572 The composition distribution of PM_{2.5} (Fig. 12b) has a similar distribution for the simulations
573 with and without aqueous phase chemistry over NWIGP where fog did not occur. The primary
574 aerosols are higher (BC > 9%, OC ~ 16-30%, OIN > 50%), than the secondary aerosols (<5%). While
575 the model requires fog for accelerated formation of secondary inorganic aerosol, experimental data
576 (Fig. 7) supports significant formation of secondary inorganic aerosol at elevated RH levels even in
577 haze aerosol (Acharja et al., 2022). On the other hand, the central and east IGP stations are fog-
578 covered and therefore, there is an increase in secondary aerosols especially SO_4^{2-} and NH_4^+ when
579 aqueous phase chemistry is included in the simulation. SO_4^{2-} is chemically produced via aqueous
580 phase chemistry in cloud water, hence the abrupt increase whereas NH_4^+ maintains a gas-aerosol and
581 gas-cloud equilibrium with NH_3 and SO_4^{2-} via neutralizing the drop or aerosol. NO_3^- is high in the
582 model compared to SO_4^{2-} and NH_4^+ and it decreases by ~1-2 % with aqueous phase chemistry. We

583 observe a small increase in NO_3^- during fog, however it drops as fog intensifies, more rapidly than that
584 without aqueous phase chemistry likely due to increase in dry deposition. This results in lower
585 average NO_3^- to $\text{PM}_{2.5}$ ratio with aqueous phase chemistry. Moreover, NO_3^- is high over the fog
586 covered CIGP and EIGP compared to NWIGP suggesting that transport and chemistry of NO_x in
587 CIGP and EIGP produce more HNO_3 . Aerosol NO_3^- is also in equilibrium with HNO_3 and it is formed
588 only if excess NH_3 is available beyond the sulfate neutralization. Thus, NH_4^+ and NO_3^- changes are
589 likely due to changing the partitioning between gas and liquid based on the production of sulfate.

590 $\text{PM}_{2.5}$ is mostly composed of organic aerosols (OA) over CIGP and EIGP (Lalchandani et al.,
591 2021; Srinivas and Sarin, 2014) whereas $\text{PM}_{2.5}$ is OIN (dust) and OA over NWIGP (Ram et al., 2012a;
592 Sharma and Mandal 2023). Although observational studies report Cl^- as one of the largest contributors
593 (12-17%) to $\text{PM}_{2.5}$ after the organics (Lalchandani et al., 2021; Pant et al., 2015) during winter, Cl^- is
594 largely underestimated by the model as discussed in section 4 and contributes only ~3%. A small
595 increase (2-4%) in secondary organic aerosols (SOA) from glyoxal production in aerosols occurs for
596 the simulation with aqueous phase chemistry included during intense fog, suggesting there are
597 feedbacks between cloud chemistry (without glyoxal aqueous chemistry) and aerosol chemistry.
598 However, similar to NO_3^- , average SOA (ASOA (anthropogenic)+BSOA (biogenic) + GlySOA)
599 shows a decrease when aqueous phase chemistry is included. SOA contributes significantly to organic
600 aerosol loading over IGP (Kaul et al., 2011; Mandariya et al., 2019).

601 The WRF-Chem results on aerosol composition during fog behave similarly to observational
602 studies. For example, Ram et al., (2012a) reported an increase of EC, OC, and WSOC concentrations
603 by ~30% during fog and haze events at Allahabad, a location in the Central IGP, and a marginal
604 increase of these constituents at Hisar (NWIGP). Several studies report an increase in inorganic ions
605 (NH_4^+ , NO_3^- , and SO_4^{2-}) during fog over IGP and elsewhere (Gundel et al., 1994; Ram et al., 2012a).
606 Recent studies suggest that a significant fraction of atmospheric particulate matter in the IGP is
607 comprised of carbonaceous aerosol (~30–35% of the PM) and water-soluble inorganic species (~10–
608 20% of the PM) during October–January when emissions from biomass burning (including residential
609 heating) are dominant over IGP (Ram et al., 2012b; Rengarajan et al., 2007; Tare et al., 2006).

610 Both the simulations with and without aqueous-phase chemistry include the AR feedback. The
611 aqueous chemistry increases the mass of $\text{PM}_{2.5}$ and the size of the aerosols, both of which contribute to
612 AR feedback, thus increasing RH and PBL stability. The increase in RH also saturates the air,
613 promotes aerosol growth by water uptake, and thus favors fog formation. Since the secondary
614 inorganic aerosols are scattering aerosols, the increased scattering of radiation further reduces the
615 solar radiation reaching the surface (Fig. 14a). Over CIGP the presence of higher aerosol loading
616 reduces the T2 during daytime, particularly on the 24th of December which then reduces the PBL
617 height and increases RH near the surface (Fig. 14b). These conditions favor fog formation over the
618 CIGP. Further, the fog water content with aqueous-phase chemistry is higher than that without
619 aqueous-phase chemistry on 24th December post-midnight (Fig. 13b). This is likely due to saturation

620 of air due to increase in RH and lower T2, induced by the AR feedback caused by the increase in
621 PM_{2.5}. Although the difference in T2 is small (<0.4), favourable conditions mentioned above are
622 conducive to fog formation. Because aqueous chemistry increases sulfate concentrations, the size of
623 the aerosols also increase. The increased aerosol size, which can grow further by water uptake, also
624 impacts the solar radiation reaching the surface, affecting fog formation and dissipation.

625

626 **7 Effect of AR feedback and aqueous chemistry on the duration of fog**

627 Aerosol and its radiative effects impact fog characteristics, including the fog liquid water content
628 (LWC), the fog lifetime over a region and hence its spatial and temporal distribution. Variations of fog
629 LWC in WRF-Chem contrast the fog in the CIGP and EIGP (Figure 15) as well as among the three
630 experiments (with aqueous chemistry plus AR feedback, with aqueous chemistry without AR
631 feedback, and without aqueous chemistry but with AR feedback). WRF-Chem does not simulate fog
632 over NWIGP in the model for the study period. In Figure 15, only foggy grid points are considered for
633 the first fog event on 23-24 December. The LWC is 5-15% higher with AR feedback than without AR
634 feedback and without aqueous phase chemistry for both CIGP and EIGP. The interquartile range is
635 larger for the simulation with and without AR feedback than without aqueous phase chemistry in
636 CIGP showing large variability in the LWC. On the other hand, in EIGP the variability in LWC is
637 greater in the simulation with AR feedback compared to the other two experiments.

638 The formation and dissipation times of the two fog events for the three experiments are listed
639 in Tables 2 and 3 for CIGP and EIGP. The 23-24 December fog starts forming two hours earlier and
640 the 24-25 December fog forms one hour earlier in both CIGP and EIGP with AR feedback than
641 without AR feedback. In the simulation without aqueous phase chemistry, fog formation is delayed by
642 an hour or two compared to the simulation with aqueous chemistry plus AR feedback in CIGP. In
643 EIGP the 23-24 December fog forms at the same time with AR feedback and without aqueous phase
644 chemistry while the 24-25 December fog is delayed by an hour without aqueous phase chemistry. Fog
645 dissipation usually occurs after sunrise when the shortwave radiative warming at the surface warms
646 the air, which results in PBL mixing. In addition, absorbing aerosols like BC affect fog dissipation by
647 increasing the radiative heating in and above the fog. We find an increase in BC and shortwave
648 heating in the PBL with AR feedback (Fig. 10,11) and warming over CIGP with AR feedback. Fog
649 intensity starts to decrease after 01:00 UTC (06:30 IST), however, in our study, we find that the fog
650 dissipates completely in the afternoon (~10:00 UTC or 15:30 IST) for both the simulations with AR
651 feedback and no aqueous chemistry while an hour later without AR feedback in CIGP. Fog dissipation
652 is delayed in EIGP with AR feedback compared to that without AR feedback and without aqueous
653 phase chemistry. In both the regions, fog lifetime increases with AR feedback. All the stations,
654 however do not show the same pattern, for example, the 23-24 December fog in Lucknow forms and
655 dissipates at the same time for simulations with AR feedback and without aqueous phase chemistry,
656 and the 24-25 December fog forms later with AR feedback than without AR feedback. Patna shows no

657 difference in the 24-25 December fog formation in all the three experiments. To gain better insights on
658 the fog timing, we recommend that simulations at higher spatial and temporal resolutions be
659 performed to represent better the fog dynamics at point locations. Furthermore, there are other
660 important factors to consider, e.g., improved emissions, better simulations of aerosol chemical
661 composition, and evaluation of aerosol deposition.

662 The AR feedback and aqueous-phase chemistry have the potential to impact aerosol-fog
663 interactions. We can learn about the effect of the aerosol-radiation interactions on CCN concentrations
664 because the WRF-Chem model calculates the CCN concentrations at different supersaturations as a
665 diagnostic output. We compare CCN at 0.02% supersaturations, a value typical of fog, among the
666 three experiments. For the 23-24 December fog in CIGP, hourly CCN concentrations are ~10% higher
667 for the simulations with AR feedback with or without aqueous chemistry than with no AR feedback
668 (Figure S8) during the first 8 hours of the fog event (16:00-24:00 IST 23 December). Surprisingly, the
669 simulation with no aqueous chemistry has higher CCN concentrations than the simulation with
670 aqueous chemistry, as more CCN are expected with aqueous chemistry. However, the dry deposition
671 flux (ddmass) also increases in dense fog which causes rapid loss in CCN and activated aerosols
672 during fog events with the AR feedback (Fig. S7) and more so without aqueous-phase chemistry.
673 Shao et al. (2023) examined aerosol-fog interactions for two consecutive fog events by comparing
674 WRF-Chem results with current emissions strengths to those with low emission strengths. They show
675 that the first fog event promotes formation of the second fog event leading to wider fog distribution,
676 and longer fog lifetime favoured by multiple feedbacks including AR feedback i.e., low temperature,
677 high humidity and high stability similar to our study. While Shao et al. (2023) observe a delay in
678 dissipation of the first event and early formation of second fog event, we find an early dissipation and
679 early formation of fog with AR feedback as discussed earlier in this section. In summary, aqueous
680 phase chemistry together with AR feedback promotes early formation of fog while AR feedback alone
681 promotes early dissipation of fog and plays a critical role in the formation and evolution of the fog
682 over IGP.

683

684 **8 Conclusions**

685 The effects of aerosol-radiation (AR) feedback and aqueous chemistry in air quality and fog
686 have been assessed over IGP. We carried out three experiments using WRF-Chem testing different
687 combinations of PBL schemes and meteorology initial and boundary conditions. The best
688 representation of surface meteorology for the IGP region for the case study (December 20-24, 2017)
689 used ERA-Interim reanalysis to drive the meteorology and ACM2 PBL scheme with soil moisture
690 nudging to ERA-Interim. With this meteorology configuration for WRF-Chem, evaluation of aerosol
691 concentrations with measurements and the impact of aerosols on atmospheric processes during fog
692 were examined. Further, we included trash-burning emissions to represent anthropogenic chloride
693 aerosols in our configuration. Incorporation of trash burning emissions did improve the model

694 simulations of $PM_{2.5}$ and better captured the day-to-day variability of $PM_{2.5}$ in IGP, however
695 underestimated its magnitude compared to CPCB observations. Moreover, secondary aerosols
696 particularly, chloride aerosols are underestimated in the model. This underestimation is likely caused
697 by a low bias in the residential burning emission inventory and a failure of the emission inventory to
698 represent residential sector emissions from the use of trash as cheap heating fuel properly. AOD
699 regional distribution is predicted well by the model for most of the IGP. However, AOD is
700 underestimated over NWIGP likely due to an underestimation of fugitive emissions during wintertime
701 cold spells.

702 The AR interactions showed a significant impact on meteorology and air quality over IGP. A
703 WRF-chem simulation with AR interactions resulted in a lower PBL height by ~50-270 m compared
704 to a simulation without AR interactions leading to accumulation of aerosols and moisture near the
705 surface. Reduced surface shortwave radiation flux and the surface sensible and latent heat fluxes due
706 to aerosol radiative effect suppressed the turbulence resulting in a stable PBL. The shallow PBL
707 further increased surface $PM_{2.5}$ ($> 8 \mu g m^{-3}$) and RH (2-8%) over IGP and this positive feedback
708 mechanism promoted thickening of fog over IGP. However, an increase in absorbing aerosols in the
709 PBL gave negative feedback, increasing the shortwave heating and temperature particularly over
710 CIGP. Fog forms when air is saturated which occurs when the surface temperature is reduced or the
711 moisture content increases causing saturation of air. This study suggests that increase in RH saturated
712 the air and the increase in aerosols favoured fog formation as depicted by the thickening of fog
713 intensity. Aqueous phase chemistry on the other hand contributed significantly to secondary aerosols
714 in the fog, especially sulfate aerosols, indicating substantial formation of secondary aerosols in the
715 cloud. The underpredicted secondary aerosols over NWIGP where no fog occurred implies
716 underestimation of formation of aerosols through gas and aerosol chemistry in the model. This
717 underestimation could also be linked to an underestimation of pH in the default MOSAIC scheme
718 (Ruan et al., 2022) which slows the secondary aerosol formation, or an underestimation of the aqueous
719 sulfur oxidation in haze aerosol at $> 80\%$ RH before the onset of fog (Acharja et al., 2022), or missing
720 multiphase oxidation processes (Wang et al., 2022). Nevertheless, we find that the model successfully
721 simulates the same changes in the inorganic composition during fog in IGP as reported by
722 observational studies referred earlier in section 6. We also observed that AR feedback with aqueous
723 chemistry initiated the fog formation 1-2 hours earlier than the initiation time in the simulation
724 without AR feedback and without aqueous phase chemistry whereas AR feedback alone led to early
725 dissipation of fog. In addition, fog acted as an important sink of aerosols in a polluted environment
726 with increased dry deposition with cloud water. Thus, AR feedback and aqueous chemistry play a
727 significant role in modulating the distribution and concentration of aerosols and evolution of fog in the
728 PBL.

729 The large emission of aerosols and trace gases in the IGP makes the atmospheric dynamics as
730 well as chemistry complex, suggesting the need for more studies using both models and ground-based

731 measurements to better understand the processes. While all aerosol types interact with solar radiation
732 and reduce the surface reaching flux, presence of absorbing aerosols in the boundary layer and its
733 vertical distribution plays an important role in modulating the meteorology over IGP. It is therefore
734 crucial to improve the simulation of absorbing aerosols e.g., BC in the vertical as well as at the surface
735 to increase the accuracy in predicting formation as well as the dissipation of fog in this region.
736 Emissions from burning for residential heating are an important source of aerosols in IGP during post-
737 monsoon and winter and the inclusion of these sources in the emission inventory would improve the
738 prediction of wintertime aerosols. For example, the underestimation of chloride aerosol in the model
739 indicates unaccounted emission sources over IGP and the need for more work on better quantifying
740 trash burning emissions, which may not only improve particulate chloride in the model but also
741 improve simulations of other aerosol chemical components through aerosol thermodynamics.
742 Additionally, more detailed modeling studies are required to understand the missing chemical
743 processes if any in the model which leads to biases in sulfate, nitrate and ammonium partitioning
744 between gas and aerosol phases. We find that the change in PBL height with AR feedback is sensitive
745 to changes in LH, signifying the role of soil moisture in PBL dynamics. Several studies have reported
746 cooling over IGP due to an increase in irrigation (Kumar et al., 2017; Mishra et al., 2020). Further
747 investigations into the role of irrigation in the increasing fog events over NWIGP would help in better
748 understanding the formation and persistence of fog over this region. It can be concluded that fog
749 forecasting is a complex process due to the multiple factors involved and this work suggests that AR
750 feedback is important in fog forecasting while aqueous phase chemistry plays an important role in
751 defining the composition of aerosols over IGP.

1305

1306 Figure 15 Averages (stars), medians (horizontal lines), quartiles (boxes), maxima, and minima for
 1307 LWC (QCloud) averaged over CIGP (left panel) and EIGP (right panel) for the fog event on 23-24
 1308 December 2017. Gold is for the simulation with AR feedback and aqueous chemistry, magenta for the
 1309 simulation with no AR feedback but includes aqueous chemistry, and blue for the simulation with AR
 1310 feedback but no aqueous chemistry. WRF-Chem does not produce fog in the NWIGP during the study
 1311 period.

1330 Table 2: Table showing the start time of fog 2 on 24 December 2017 with LWC for the sensitivity
 1331 experiments, with AR feedback, no AR feedback and no Aqueous phase chemistry. Fog2 end time
 1332 could not be noted as simulation ended on 25 December 2017, 00UT (5:30 IST) before fog2
 1333 dissipates.
