

Response to Reviewer 1

General Comments: Kalmaegi was a fast-moving TC. At 8 m/s, the TC traverses ~600 km in 1 day and spent ~6 hours traversing AE1 (or AE2) with a diameter of about 150 km. In such a super-critically moving storm, most of the wind effect on the ocean is therefore through mixing (including perhaps that caused by near-inertial internal wave breaking in the upper ocean in the wake of the storm) rather than the wind stress curl. The latter would require that wind acts on the ocean in a time scale longer than the inertial period (~1.5 days at 19N). I understand the authors' hypothesis of the negative WSC (thus convergence) on the left side, etc., but I don't think it is a demonstrable one in this case and is most likely incorrect. The increased AE1 after Kalmaegi (Fig.3, etc.) is likely a complex eddy adjustment process. One may suspect such adjustment also from Fig.3 in which the "warm" area between AE1 and AE2, including that on the left side, shrinks or weakens. That area would have expanded following the authors' hypothesis.

Response: We would like to thank you for your careful reading, helpful comments, and constructive suggestions, which have significantly improved the presentation of our manuscript. We have carefully considered all comments from the reviewer and revised our manuscript accordingly. The manuscript has also been double-checked, the typos and grammar errors we found have been corrected. The changes are highlighted in the manuscript. All page numbers refer to the revised manuscript file with tracked changes.

Thank you for your comments.

We agree with the reviewer that during the forcing stage of a fast typhoon, there are exists near inertial waves and they are very important. Here we show the snapshots of AE1 through its lifetime from 26 June to 14 October, 2014. We can see that the entire buoy array located within the AE1 from 31 July to 14 August (Figure S1). It can explain the near-inertial waves propagated downward into ocean interior from this period (Figure S2). It can be seen that near-inertial currents during 18 July to 19 August and 16-30 September, with a maximum

near-inertial velocity of 0.61 cm s^{-1} , which are affected by typhoon Rammasun (16-18, July) and Kalmaegi (14-16, September). The near-inertial energy of Kalmaegi lasts from surface to 200 m, but near-inertial currents caused by typhoon Rammasun lasts longer, it stays at upper 50 m on 18-24 July, then the near-inertial energy enters and traps in AE1, it transmits downward since 25 July and stay at 50-200 m until 17 August. The transfer of energy from anticyclonic eddy to near-inertial waves is the main reason for the downward propagation and longtime persistence of near-inertial energy (Chen et al, 2023). The near-inertial velocity distribution pattern of Station 4 during the period from 30 July to 19 August is different from station 1 and 4, because AE1 gradually moves away from station 4 (located in the northeast of the bouy array, Fig. S1), it captures weakest near-inertial energy. Due to the westward movement of AE1, the eddy center is near station 2, only station 2 catches the subsurface near-inertial signals during the period of 12 August to 8 September (the red box area in Fig. S2), and it is relatively small, with a maximum velocity of 0.18 cm s^{-1} .

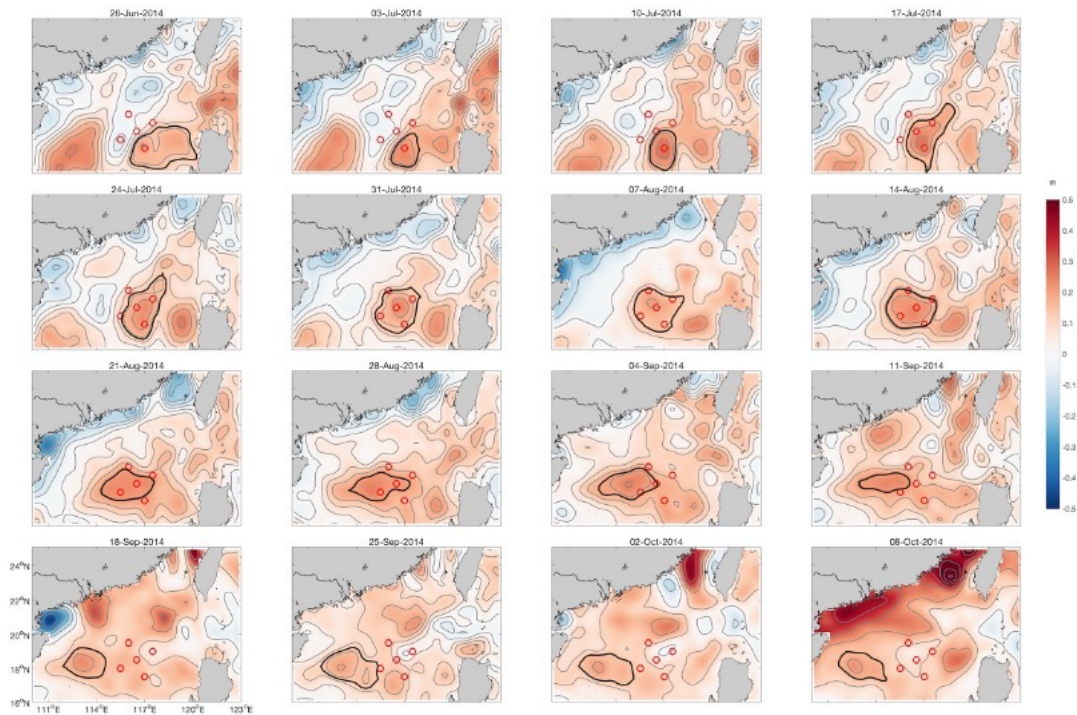

Figure S1. Eddy boundaries of AE1 and its distance from the bouy array during its lifecycle (26 June to 8 October). The color and gray contour lines represent sea level anomaly, while the black solid contours are AE1's boundaries. The five red dots represent the positions of 5 bouys.

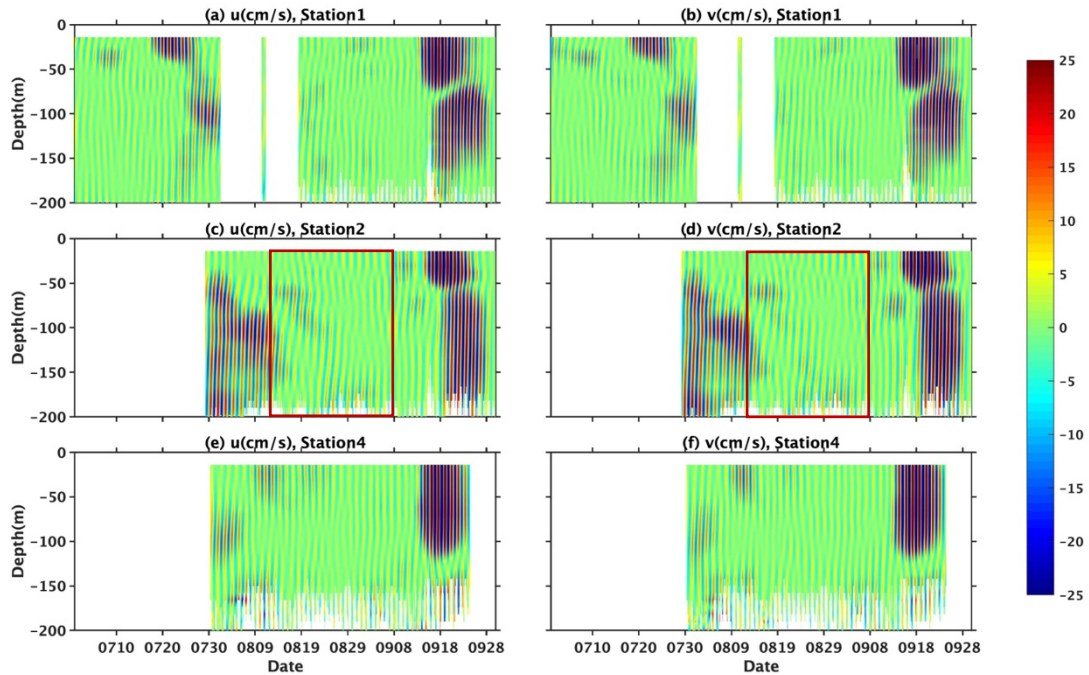

Figure S2. Eastward(a,c,e) and northward(b,d,f) near-inertial currents in the upper 200 m observed at station 1, 2 and 4.

Chen Z, Yu F, Chen Z, et al. Downward Propagation and Trapping of Near-Inertial Waves by a Westward-moving Anticyclonic Eddy in the Subtropical Northwestern Pacific Ocean[J]. *Journal of Physical Oceanography*, 2023.

Since our corresponding author Han Zhang has previously published 6 papers (listed at below) and discussed the ocean response of typhoon Kalmaegi from multiple perspectives, including variations of near-inertial energy, vertical temperature, heat changes and their mechanisms during typhoon, so in this paper, near-inertial effect and mixing is not the focus. Moreover, AE1 is already far from the buoy array during typhoon Kalmaegi passed over NSCS, so the near-inertial waves at this period has little impact on AE1 and is excited by the first baroclinic mode (Zhang et al, 2017). Furthermore, daily reanalysis data is insufficient to study near-inertial waves in AE1 at this time.

Wu R, Zhang H, Chen D, et al. Impact of Typhoon Kalmaegi (2014) on the South China Sea: Simulations using a fully coupled atmosphere-ocean-wave model[J]. *Ocean Modelling*, 2018, 131: 132-151.

Wu R, Zhang H, Chen D. Effect of Typhoon Kalmaegi (2014) on northern South China Sea explored using Multi-platform satellite and buoy observations data[J]. *Progress in Oceanography*, 2020, 180: 102218.

In addition, we believe that the ocean responds quickly to wind stress curl caused by typhoon Kalmaegi with no time lag. Ekman layer depth (D_E) varied with typhoon passage is shown in Fig. S3, when Kalmaegi approaches at 0000 UTC on 14 September, the mean D_E within AE1 is only 21 m, while AE2 is 114 m, indicates that AE2 has already influenced by typhoon Kalmaegi. Then D_E of AE2 sharply deepens, reaching a maximum depth of 241 m (Fig. S4) at 0000 UTC on 15 September when the center of Kalmegi is near AE2. As Kalmaegi moved northwest, the D_E within AE1 reached its maximum depth of 262 m at 0000UTC on 16 September. The trends of D_E within AE1 and AE2 are almost consistent, but AE1 lags AE2 by one day. From 15 September, D_E within AE1 and AE2 gradually shallower, with the minimum D_E of 60 m, which is 28 m higher than before typhoon, indicating that typhoon's effect through wind is still exist. For AE2, D_E reached its minimum of 45 m at 0000 UTC on September, later increased gradually under the influence of tropical storm Fung-wong.

Due to the fact that near-inertial oscillation mainly manifests as the transfer of vertical energy, and Ekman Pumping can truly bring about vertical velocity changes, we believe that the theory of Ekman Pumping can be used to explain the vertical variation of AE1 and AE2. We have added these sentences at lines 447-456.

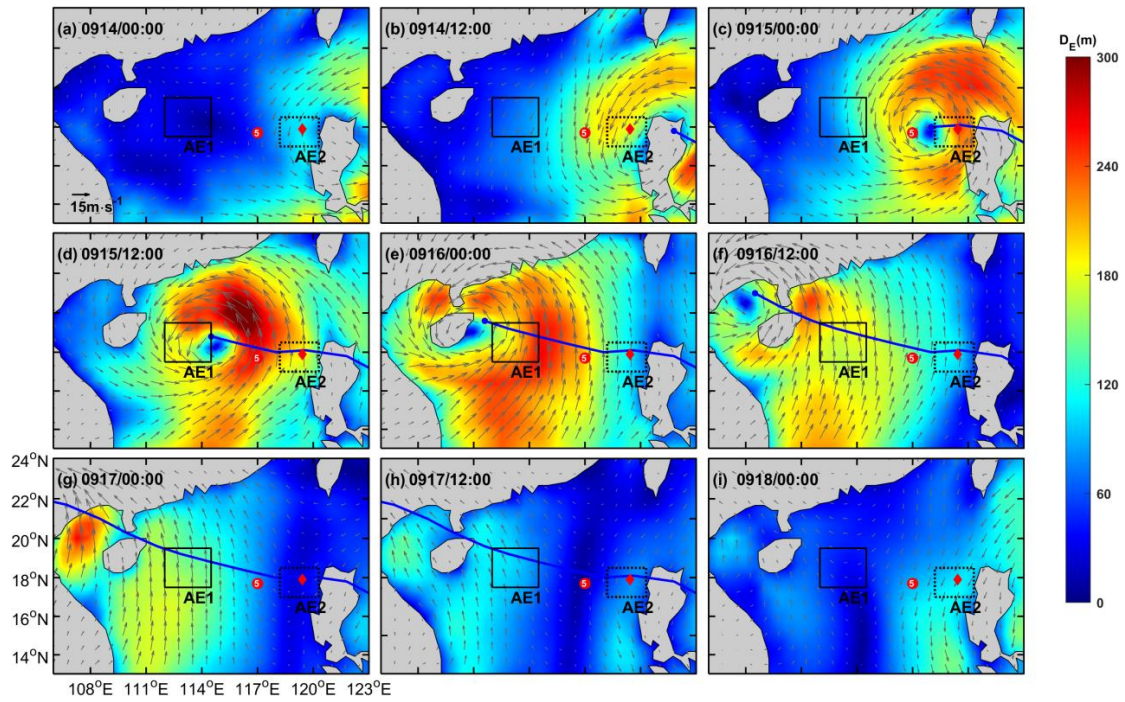

Figure S3. Ekman layer depth (DE) from 14 September to 18 September (a-i). The color represents the DE, the blue solid line is the path of Kalmaegi, the red dot and diamond are the positions of Station 5 and Argo 2901469 on 15 September, respectively. (Fig. 10 in manuscript)

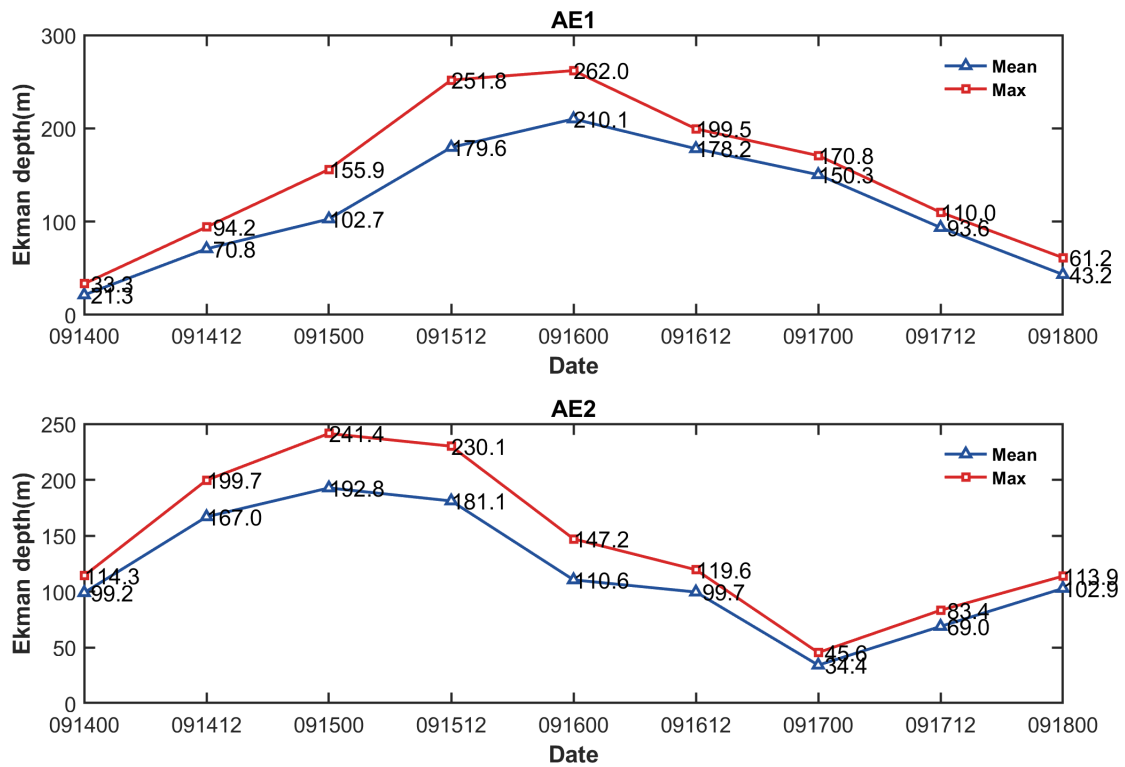

Figure S4. Timeseries of D_E from 14 September to 18 September within AE1 (a) and AE2 (b), respectively. The red line is the maximum D_E and the blue line represents the mean maximum.

Regarding the second question, it can be seen from Figure 9 (line 458) that during typhoon Kalmaegi, the Ekman Pumping Velocity (EPV) on the left side of the typhoon path has both positive and negative values, so there exists both upwelling and downwelling on the left side of the path. In AE1, vertical velocity is downwelling, and most other places on the left side are upwelling. With the effect of advection, the overall cooling effect is greater than the warming effect, so the warm area is decreasing.

Two other general comments. 1) AE1's increased amplitude, R_o and $EKE = 1.3 \text{ cm}$, $1.4e-2$ and 107 (cm/s)^2 are small. Are they statistically significant, and were errors and confidence levels estimated? Similarly for AE2. 2) Inertial oscillatory response persists long (~5 days and longer) after a storm passes (see e.g. Wu et al. Effect of Typhoon Kalmaegi (2014) on northern South China Sea explored using Multi-platform satellite and buoy observations data; Prog Oceanogr. 180 (2020) 102218). The effects of inertial motions on the Authors' results and analyses were not discussed and I am unsure, for example, how the effects were filtered out or accounted for and how they may affect their estimates.

Response: Thank you. Because there are only two eddies studied here, too few samples to conduct significant testing. Although the increase (decrease) of amplitude, R_o , EKE of AE1 (AE2) are small, their proportion is not small compared to their average value. So we add these sentences on abstract at lines 14-17:

The amplitude, Rossby number (R_o) and eddy kinetic energy (EKE) of AE1 increased by 1.3 cm (5.7%), 1.4×10^{-2} (20.6%) and $107.2 \text{ cm}^2 \text{ s}^{-2}$ (49.2%) after the typhoon, respectively, while AE2 weakened and the amplitude, vorticity and EKE decreased by 3.1 cm (14.6%), 1.6×10^{-2} (26.2%) and $38.5 \text{ cm}^2 \text{ s}^{-2}$ (20.2%), respectively.

2) Thank you for recommending a very good paper and results. We have cited some of the conclusions from Wu et al (2020) at introduction of line xx. From Fig. S2, the near-inertial oscillation can persistence longer than 1 month.

Wu R, Zhang H, Chen D, et al. Impact of Typhoon Kalmaegi (2014) on the South China Sea: Simulations using a fully coupled atmosphere-ocean-wave model[J]. Ocean Modelling, 2018, 131: 132-151.

Other Comments:

L14: Rossby number ($Ro = \text{relative vorticity}/\text{Coriolis parameter}$);

Response: Thanks, we have added this definition.

L16: Rossby number;

Response: Thanks you, it have been corrected.

L166: vertical feedback of the ocean by ... Kalmaegi: Not sure what this means, what "feedback", maybe "response..."?

Response: Sorry for misunderstanding. It is proper to use "response", we have replaced it.

Also: I assume GLORY assimilates Argo data but not the Station data. If so, then it is unsurprising that GLORY agrees with ARGO but not Station 5 (Figure 1).

Only Station 5 on the left side of the storm was used to support the authors' hypothesis. To support (refute?) the Authors' hypothesis I suggest using data from other Stations (except #3), right and left of Kalmaegi.

Response: Due to the lack of temperature data at S1, we added the vertical profiles of S2 and S4 were compared with GLORYS12v1. The RMS between GLORYS12V1 and Station 2 (Station 4) is 0.14 (0.10), with significant deviations in the mixed layer and thermocline.

Although compared to S5, the RMS of S2 and S4 is a little larger, but still acceptable.

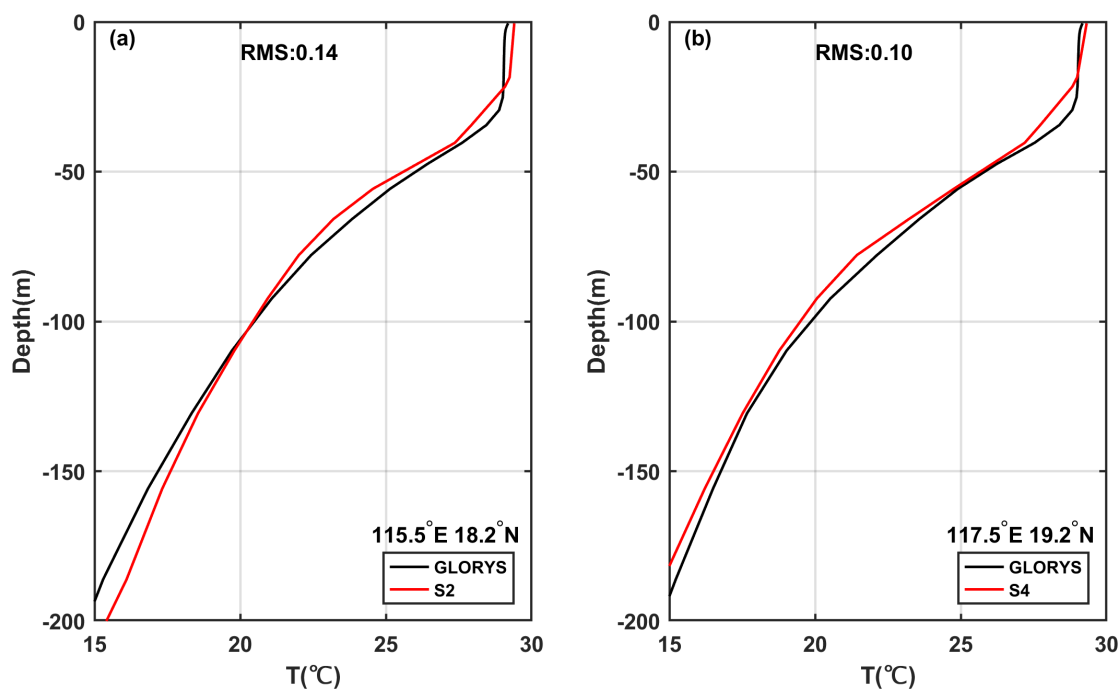

Figure S5. Evaluation of GLORYS12V1 data performance during September 2014. (a) Vertical monthly mean temperature within the anticyclonic eddy AE2 (119.5°E 17.9°N) as measured by Station 2 (115.5°E 18.2°N) . (b) Comparison of vertical monthly mean temperature recorded at Station 4 (117.5°E 19.2°N).

L223: ... weak wind stress curl, to be more precise. The term "wind shear" is also customarily taken as "vertical wind shear" in TC studies in meteorology so can be confusing.

Response: Thank you, the word "vertical" has been added to be more precise.

L245: ... with 6-hourly dots.

Response: Thank you, the word "6-hourly" has been added to be more precise.

All of the co-authors are so grateful to the reviewer for the time spent on our manuscript. The comments and suggestions provided by the reviewer are invaluable for us to improve our manuscript. We are so appreciated.

Response to Reviewer 2

General comments:

The authors investigated the responses of two warm eddies to a typhoon using observational and reanalysis data. There have been lots of efforts on eddy feedback to TC evolution, while our understanding of eddy response to TCs remains limited. The work is potentially interesting and contribute to broaden the knowledge of TC-eddy interaction, but I have some comments before the paper can be published. I recommend moderate to minor revision of the manuscript.

Response: We would like to thank you for your careful reading, helpful comments, and constructive suggestions, which have significantly improved the presentation of our manuscript. We have carefully considered all comments from the reviewer and revised our manuscript accordingly. The manuscript has also been double-checked, the typos and grammar errors we found have been corrected. In the following section, we summarize our responses to each comment from the reviewer. We believe that our responses have well addressed all concerns from the reviewer. The changes are highlighted in the manuscript. Please see below, in blue and black, for a point-by-point response to the reviewer's comments and concerns. All page numbers refer to the revised manuscript file with tracked changes.

Primary comments:

1. The motivation of conducting the study should be more clarified. Just stating that “However, there has been relatively limited exploration of different responses exhibited by warm eddies under the influence of typhoons” is not adequate from my opinion. There have been several studies on the eddy response to TCs. The authors should be more carefully summarize what have been reported from these previous studies, and what new knowledge will be reported in this study.

Response : Thank you for your nice comments on our manuscript. According to your suggestions, we re-summarized what has been reported in previous studies of eddy-typhoon interactions, as well as what new knowledge will be reported in this study. please check Lines 98.

“Previous studies on the interaction between eddies and typhoons have primarily focused on two aspects, one is the influence of ocean eddies on typhoons: the enhancement of warm eddies on typhoons; and the other is how typhoons affect ocean eddies: the response of cold eddies to typhoons. However, the exploration of the response of warm eddies under the influence of typhoons and the three-dimensional response of eddies to typhoons is relatively limited. In this paper, we explore the effects of the different positions of warm eddies on the response of eddies as well as the changes in their three-dimensional thermohaline structure characteristics, which will provide inputs to the study of eddy-typhoon interactions.”

2. The writing of the paper needs a substantial improvement. There are lots of sentences that are hard to follow and hinder understanding. The logics between paragraphs should be clear. On

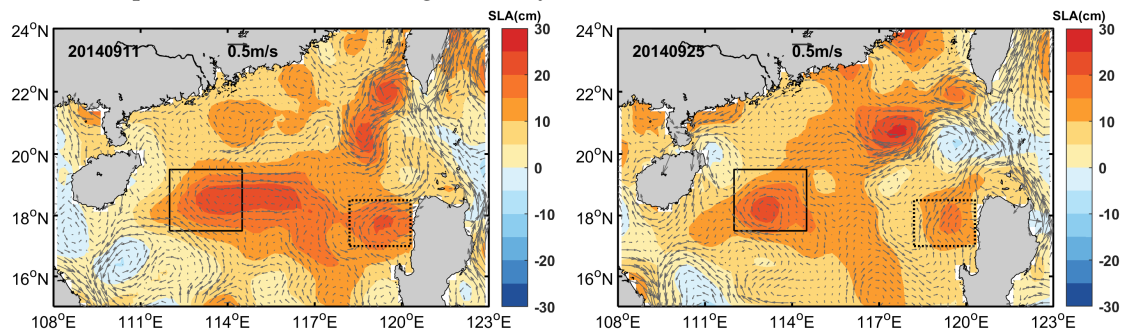

Line 31, the word of “typhoon” is used, but in the following the “tropical cyclone” is used instead. The paper should keep consistency in word usage.

Response : Thanks for your suggestion. As some papers and also our study show that some tropical storm also play important role in air-sea interaction. So we change the word “typhoon” to “Tropical cyclones (TCs)” in Line 31. We also keep consistency in the revised manuscript.

Specific comments:

1. Is it reasonable to use the rectangle areas represent AE1 and AE2 (Figure 1)? As eddies always move during typhoon.

Response : Thank you for your asking. We have figured the spatial distribution of SLA and geostrophic current from 11 September to 25 September, and both AE1 and AE2 were active within the rectangular frames during this period. Here, we just show two days’ snapshots, on 25 September (right panel), these two eddies still in the rectangular frames. Moreover, the moving speed of the two eddies from 11 September to 25 September was calculated through the “Mesoscale Eddy Trajectory Atlas” product. The mean moving speed of AE1 is 0.18 m s^{-1} , and 0.07 m s^{-1} for AE2 during this period, so the mean travelling distance is about 217.7 km and 84.7 km, respectively, which are still in the rectangular frames during this period. Further more, we focus on the fixed area are helpful for comparison. So it is reasonable to use rectangular areas to represent the eddies during the study.

2. There are several common issues with the figures in the manuscript that need to be addressed, including the addition of x-labels and y-labels, as well as the unification of font sizes etc. Specific comments are as follows:

1). Figure 1: The first letter of “depth” in Y-label needs to be capitalized.

Response: Thanks, the figure has been modified as suggested.

2). Figure 4: Just keep one arrow legend and text of “15 m/s” in (a), the quiver and the text should be larger.

Response: Thanks, the figure has been modified as suggested.

3). The coordinate axes are duplicated in Figure 5, delete the x-axis and y-axis in Figure 5 (a), (d), (g), (j), just like Figure 4; Set the range of SST colorbar as 26 to 31 °C; Change the red dots to larger black dots.

Response: Thanks, the figure has been modified as suggested.

4). Figure 6: The first letter of “date” needs to be capitalized, like “Date”.

Response: Thanks, the figure has been modified as suggested.

5). Figure 7: The first letter of “date” and “depth” needs to be capitalized; The unit of “psu” should be “PSU”.

Response: Thanks, the figure has been modified as suggested.

6). Figure 8: The first letter of “date” and “depth” needs to be capitalized; Please use the density excess replace the density, that means density minus 1000 kg. m⁻³; The unit of buoyancy should be written as “N² (10⁻⁴ s⁻²)”.

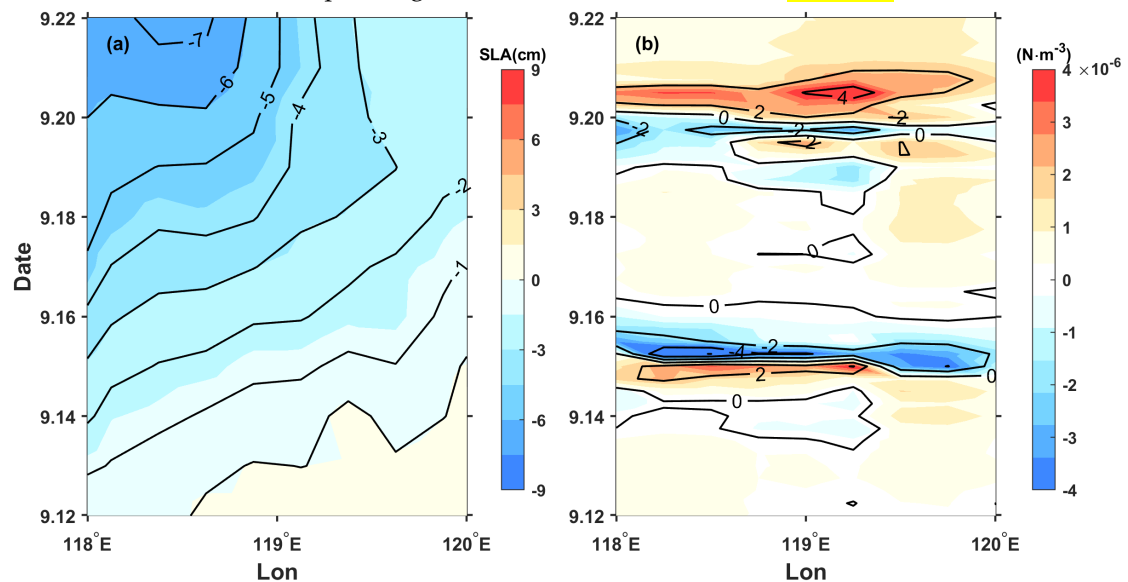

Response: Thanks, the figure has been modified as suggested.

7). Figure 9: The first letter of “depth” needs to be capitalized; “psu” should be “PSU”.

Response: Thanks, the figure has been modified as suggested.

8). Figure 10: The unit of wind stress curl unit should be “N.m⁻³”, so the colorbar will make some confuse, move “N.m⁻³” to the right side of colorbar or another proper place. To compare AE1 and AE2, the same figure as Figure 10 but for AE2 is needed.

Response: Thanks, the figure has been modified as suggested. The similar figure for AE2 has been added and the corresponding sentences have been added at **Line xxx.**

9). Figure 11: The first letter of “date” and “depth” needs to be capitalized.

Response: Thanks, the figure has been modified as suggested.

3. There are some spelling or inappropriate use of singular and plural in the manuscript, for example,

L39 on ‘the’ one hand

L65 the typhoon track ‘are’ more intensely

L87 of a ‘near-inertial’ wake

L118 The daily Sea Level Anomaly (SLA) and geostrophic current data ‘are’ provided by Archiving

L131 ‘database’

L156 temperature and salinity ‘from’ 1 September to 30 September 2014 ‘were’ chosen to study.

L216 ‘where’

L278 ‘passage’

L398 warm anomaly of 1.2 °C ‘was’ observed at a depth

L444 'Compared'

L508 'contributes'

Response: Thank you for your carefully reading and correction. In our resubmitted manuscript, the typos are revised at Line 39, 65, 87, 118, 131, 156, 216, 278, 398, 444 and 508, accordingly.

4. Inconsistent use of tenses. When describing the work of previous researchers, you should generally use the **past tense**. This is because those studies have been completed in the past and form part of the background for your research. When describing your own work, you should generally use the **present tense**. This helps emphasize that your results are current and still valid.

For example, L122 the data access needs to use the past tense. ?

L309-313 please use the past tense

L316-319 please use the present tense, etc?

Please check the full manuscript carefully.

Response : Thank you for your suggestions. We have corrected tense misuses in our new manuscript.

5. Many abbreviations have repeated definitions, including but not limited to:

L71 and L118 SLA duplication definitions.

'EPV' is firmly defined 4-5 times, 'Rossby number', 'SST', 'EKE', etc.

Response: Thanks. All abbreviations are only defined at the first time.

6. A mix of American and British spellings, such as Typhoon 'center' and 'centre' are appeared in the manuscript.

Response: Thanks for your careful checks. We have corrected the 'centre' to 'center' to make the word harmonized within the whole manuscript.

7. Line 650: Please check out the format of the reference.

Response: Thank you for your suggestion. We have checked the format of the reference at Line 650, it is correct. Please see the screenshot of this reference we cited.

Effects of a Warm Oceanic Feature on Hurricane Opal
