Text S1: Data Analysis

The calculations for organic matter (OM), sulfur oxidation rate (SOR), nitrogen oxidation rate (NOR), and secondary organic carbon (SOC) were performed using the following formulas:

$$OM = OC \times 1.6 \quad (1)$$

$$SOR = (SO_4^{2-}) / (SO_4^{2-}) + (SO_2) \quad (2)$$

$$NOR = (NO_3^-) / (NO_3^-) + (NO_2) \quad (3)$$

$$SOC = OC - (OC/EC)_{\min} \times EC \quad (4)$$

where OM, SOR, NOR, and SOC represent organic matter, sulfur oxidation rate, nitrogen oxidation rate, and secondary organic carbon, respectively.

The contribution rates of anthropogenic emissions and meteorological conditions were calculated using Formulas 5 and 6.

$$\text{Contribution}_{\text{meteorology}}(\%) = \frac{C_{\text{observed}} - C_{\text{deweathered}}}{C_{\text{observed}}} \times 100\% \quad (5)$$

$$\text{Contribution}_{\text{emission}}(\%) = 1 - \text{Contribution}_{\text{meteorology}} \quad (6)$$

Figure S1. Correlation of aerosol compositions with gaseous pollutants and

meteorological variables during observation. (* represent $p \leq 0.05$, **represent $p \leq 0.01$, ***represent $p \leq 0.001$)

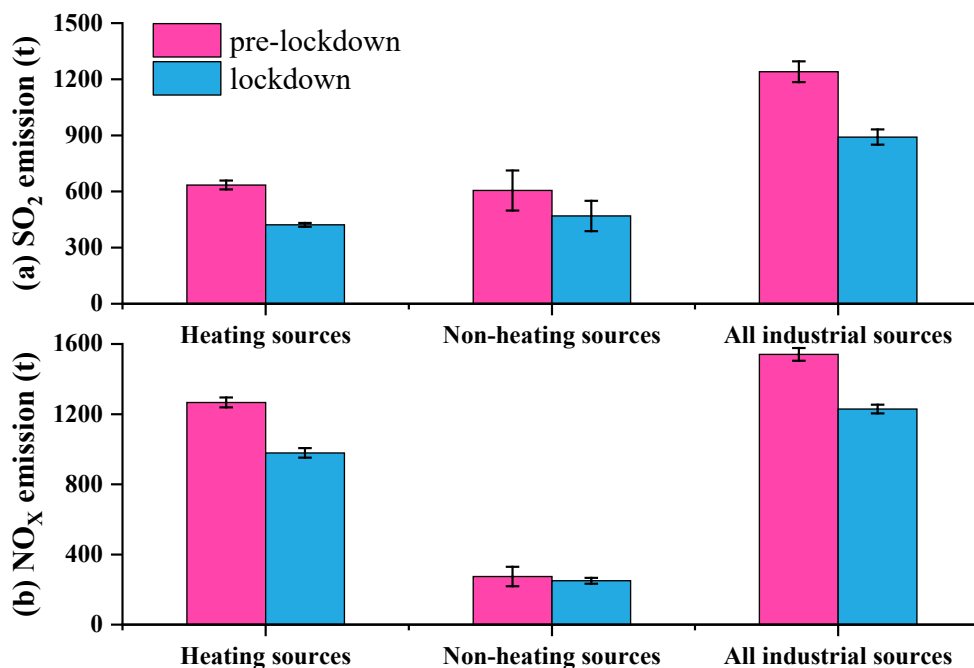

Figure S2. Comparison of (a) SO₂ and (b) NO_x emissions in different periods

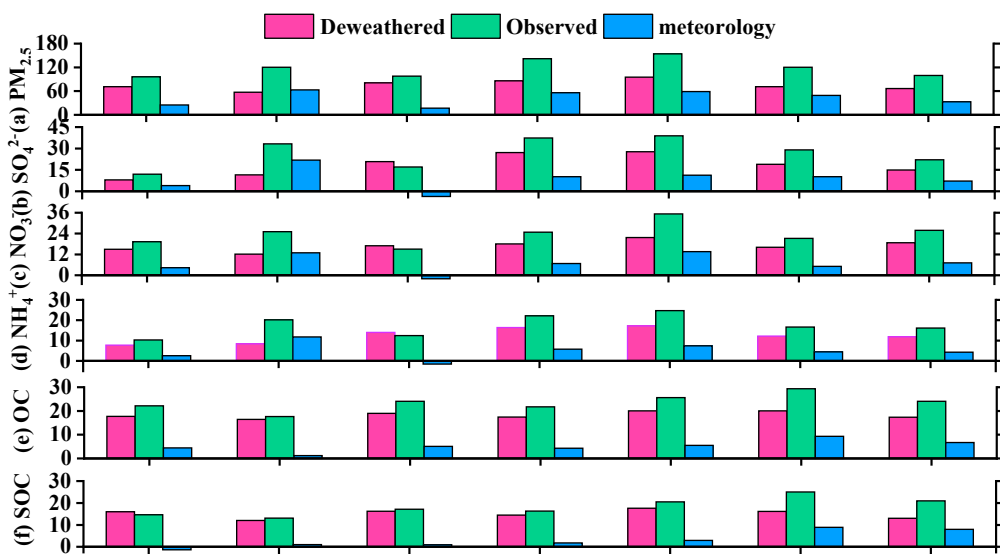

Figure S3. The contribution of anthropogenic emission and meteorological conditions to (a) PM_{2.5}, (b) SO₄²⁻, (c) NO₃⁻, (d) NH₄⁺, (e) OC, and (f) SOC during the pollution episodes.
