7 HIGHLIGHTS

- 8 • Strong aerosol-cloud relations under unstable meteorological conditions led to the
9 formation of thick precipitating clouds.
10 • In thick clouds, the activation of cloud droplets is weakly dependent on aerosols.
11 • Optically thin clouds led to a high precipitation rate.
12

13 ABSTRACT

14 Aerosol-cloud-precipitation-interaction (ACPI) plays a pivotal role in the global and regional
15 water cycle and the earth's energy budget; however, it remains highly uncertain due to the
16 underlying different physical mechanisms. Therefore, this study aims to systematically analyze the
17 effects of aerosols and meteorological factors on ACPI in the co-located precipitating (PCs) and
18 non-precipitating clouds (NPCs) clouds in winter and summer seasons by employing the long-term
19 (2001-2021) retrievals from Moderate Resolution Imaging Spectroradiometer (MODIS), Tropical
20 Rainfall Measuring Mission (TRMM) coupled with the National Center for Environmental
21 Prediction/National Center for Atmospheric Research (NCEP/NCAR) reanalysis-II datasets over
22 the Indo-Gangetic Plains (IGP). The results exhibit a decadal increase in aerosol optical depth
23 (AOD) over Lahore (5.2%), Delhi (9%), Kanpur (10.7%), and Gandhi College (22.7%) and a
24 decrease over Karachi (-1.9%) and Jaipur (-0.5%). The most stable meteorology with high values
25 of lower tropospheric stability (LTS) is found in both seasons over Karachi. In the summer season,
26 the occurrence frequency of clouds is high (74%) over Gandhi College, 60% of which are PCs.
27 Conversely, the least number of PCs are found over Karachi. Similarly, in the winter season, the
28 frequency of cloud occurrence is low over Karachi and high over Lahore and Gandhi College. The
29 analysis of cloud top pressure (CTP) and cloud optical thickness (COT) indicate high values of
30 cloud fraction (CF) for thick and high-level clouds over all study areas except Karachi. The
31 microphysical properties such as cloud effective radius (CER) and cloud droplet number

32 concentration (CDNC) bear high values ($CER > \sim 15 \mu\text{m}$ and $CDNC > \sim 50 \text{ cm}^{-3}$) for both NPCs
33 and PCs in summer. The AOD-CER correlation is good (weak) for PCs (NPCs) in winter. Similarly,
34 the sensitivity value of the first indirect effect (FIE) is high (ranging from 0.2 ± 0.13 to 0.3 ± 0.01
35 in winter, and from 0.19 ± 0.03 to 0.32 ± 0.05 in summer) for PCs and low for NPCs. The
36 sensitivity value for the second indirect effect (SIE) is relatively higher (such as 0.6 ± 0.14 in
37 winter and 0.4 ± 0.04 in summer) than FIE. Sensitivity values of the aerosol-cloud interaction
38 (ACI) are low (i.e., -0.06 ± 0.09) for PCs in summer. Furthermore, the precipitation rate (PR)
39 exhibits high values in summer season, primarily due to the significant contribution from optically
40 thick clouds with lower CDNC ($< \sim 50 \text{ cm}^{-3}$) and larger CER, and intermediate contribution from
41 optically thick clouds with higher CDNC ($> \sim 50 \text{ cm}^{-3}$).

45 effect, second indirect effect, precipitation sensitivity.

46 1. Introduction

47 The aerosol-cloud-precipitation-interaction (ACPI) and aerosol-radiation-interaction (ARI)
48 significantly influence climates at the regional and global scales (Romero et al., 2021). Assessing
49 the direct and indirect effects of aerosols is crucial to understanding and predicting the energy
50 budget and the water cycle. In the direct effect, the absorption and scattering of solar radiation by
51 aerosols lead to the warming of the atmosphere and cooling of the earth's surface (Zhou et al.,
52 2020), causing changes in the lower tropospheric stability (LTS) that further lead to modulation of
53 precipitating (PCs) and non-precipitation clouds (NPCs) (Andreae & Rosenfeld, 2008).
54 Precipitating clouds are thick clouds with significant vertical development and high moisture
55 content form under unstable atmospheric conditions, such as cumulonimbus and nimbostratus, that
56 produce precipitation reaching the ground. In contrast, non-precipitating clouds are typically thin,
57 have low moisture content, and form under stable atmospheric conditions, including cloud types
58 like cirrus, cirrostratus, altostratus, and stratus, which generally do not produce significant
59 precipitation (Houze Jr, 2014).

60 In the indirect effect, the water-soluble aerosols such as soil dust, sulfates, nitrates, and other
61 organic aerosols ejected naturally and anthropogenically serve as cloud condensation nuclei (CCN)
62 and ice nucleating particles (INP). Hence, aerosols affect the aerosol-cloud-interaction (ACI) by
63 influencing the growth of cloud droplets and cloud droplet number concentration (CDNC)
64 (Twomey et al., 1977; Albrecht, 1989; Jiang et al., 2002; Chen et al., 2011; Tao et al., 2012). The
65 increase of CDNC and decrease of cloud droplet effective radius (CER) inhibit the onset of
66 precipitation and increase the cloud lifetime (Albrecht, 1989). Conversely, the decrease in CDNC
67 and increase in CER increases the probability of precipitation rate (PR). Conversely, Stevens and
68 Feingold (2009) have shown that initially, more sea salt carried by high wind speed inhibits
69 precipitation formation. However, the same sea spray tends to seed the coalescence by producing
70 larger CER that leads to enhanced precipitation.

71 In the last few decades, most of the cultivable land of the Indo-Gangetic Plain (IGP) has been
72 replaced by urban developments. Due to the fastest growth of population, urbanization,
73 industrialization, and massive combustion of biomass and fossil fuels in residential homes and
74 factories, a decadal increase in aerosols is observed over IGP. The high aerosol loading may affect
75 the formation of tropospheric clouds and seasonal precipitation patterns (Kaskaoutis et al., 2011;
76 Singh et al., 2015; Thomas et al., 2021). The high aerosol loading makes IGP suitable for the study
77 of ACPI. Besides, frequent variations in cloud fraction (CF), extreme precipitation and drought
78 abrupt temperature changes (e.g., heat waves), and irregular unseasonal rains may cause major and
79 unavoidable hazards at local and regional levels in the future (Zhou et al., 2020).

80 In the last two decades, the scientific community has focused on quantification of ACI using both
81 observations (Feingold et al., 2003; Koren et al., 2004; Costantino et al., 2010; Wang et al., 2015;
82 Zhao et al., 2018, Guo et al., 2019; 2020; Anwar et al., 2022) and modeling techniques (Chen et
83 al., 2016, 2018; Wang et al. 2020; Zhou et al., 2020; Sharma et al., 2023). Although, a similar
84 recent study (Anwar et al., 2022) attempted to understand the sensitivities of ACI and the first
85 indirect effect of different subsets of AOD to the different conditions of RH and wind directions
86 and found a decrease (increase) in CER with aerosol loading Twomey effect (anti-Twomey effect)
87 over the monsoon (weak and moderately intensive monsoon) regions. However, the above study
88 excluded the other significant meteorological parameters such as LTS, PR, and T_{850} and was also
89 limited to the monsoon regions of Pakistan only. Further, in the context of warm rain processes, it

90 is generally understood that the high concentration of aerosols capable of serving as CCN leads to
91 enhanced CDNC known as the first indirect effect (FIE) or Twomey effect (Twomey et al., 1977).
92 It is also widely acknowledged that CDNC plays a pivotal role in cloud microphysics and
93 significantly influences the onset of precipitation and retention of water in clouds called the second
94 indirect effect (SIE) (Gryspeerd et al., 2016; Naud et al., 2017). Whilst, in the above study, the
95 analysis of CDNC is also not addressed. Therefore, the present study aims to deepen the previous
96 study (Anwar et al., 2022), by a long-term and detailed analysis of the ACPI including aerosol-
97 indirect effects for low-level liquid clouds extended over the whole IGP for understanding different
98 mechanisms (condensation, droplet growth and precipitation rate) of cloud and precipitation
99 formation.

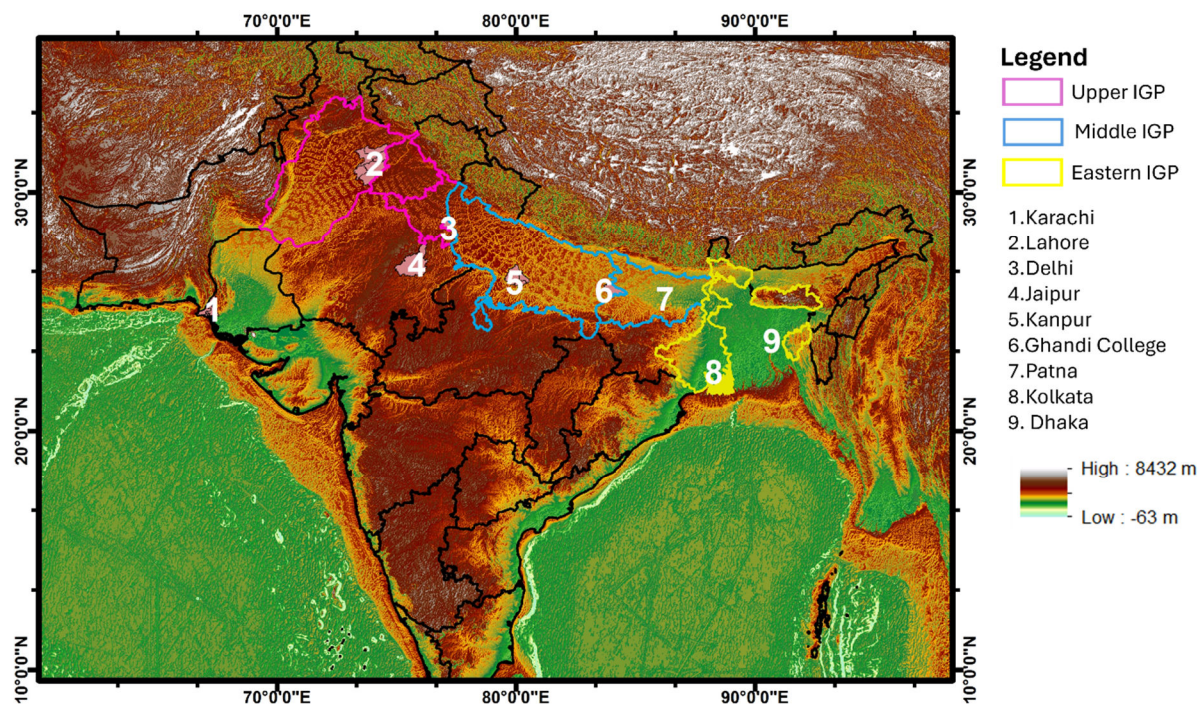

100 This study is focused on estimating the variations in sensitivities of aerosol-cloud relationship to
101 the variations in aerosol loading at specified meteorological conditions for low-level PCs and
102 NPCs in the summer and winter seasons over the IGP. This study is unique in using a large number
103 of samples, classification of liquid clouds in PCs and NPCs, further classification of clouds in low,
104 mid, and high-level clouds through joint COT-CTP histograms, quantification of the sensitivities
105 of FIE, SIE, total indirect effect (TIE), and ACI to CDNC. The significant meteorological
106 parameters considered include temperature at 850 hPa, LTS, relative humidity (RH%) at 850 hPa,
107 vertical velocity (ω), and PR. Furthermore, by utilizing the Moderate Resolution Imaging
108 Spectroradiometer (MODIS) and Tropical Rainfall Measuring Mission (TRMM) data, the
109 correlation of cloud microphysical properties (CER and CDNC) and AOD at specified values of
110 LTS and cloud liquid water path (CLWP) is examined, and precipitation sensitivity at constant
111 macro-physical condition is estimated.

112 **2. Study area and methodology**

113 **2.1. Study area**

114 The selected study area (Fig. 1) comprises the upper, middle, and eastern portions of the IGP. The
115 upper part consists of the densely populated and developed regions of the eastern part of Pakistan
116 i.e., Karachi (24.87°N, 67.03°E) and Lahore (31.54°N, 74.32°E) whereas the middle part comprises
117 the northern part of India i.e., Delhi (28.59°N, 77.22°E), Kanpur (26.51°N, 80.23°E), Jaipur
118 (26.91°N, 75.81°E), Gandhi College (25.87°N, 84.13°E), Kolkata (22.57°N, 88.36°E), Dhaka

119 (23.80°N, 90.41°E) and Patna (25.59°N, 85.13°E). The data analysis for the eastern part of IGP
120 (Kolkata, Dhaka, and Patna) is documented as supplementary materials.

121

122

2.2. Methodology

123

2.2.1. MODIS, NCEP/NCAR reanalysis-II and TRMM data

124

125 Moderate Resolution Imaging Spectroradiometer (MODIS) is a major constituent of NASA's Earth
126 Observing System (EOS). MODIS is orbiting with two onboard satellites, Terra and Aqua,
127 launched in 1999 and 2002 respectively, with a range of 2330 km spanning the entire globe in a
128 day. It provides data and information with a spatial resolution of 1° to study atmospheric processes
129 and physical structure (Kedia et al., 2014; Srivastava et al., 2015). This study uses the daily mean
130 of combined dark target and deep blue AOD at 0.55 μm , cloud top pressure (CTP), cloud top
131 temperature (CTT), CF, CER, and COT for liquid clouds from level 3 aerosol-cloud data product
132 MOD08-TERRA. Data with AOD > 1.5 are excluded to avoid potential misidentification of
133 aerosols as clouds. The following adiabatic approximation (Brennguier et al., 2000; Wood, 2006;
134 Kubar et al., 2009; Michibata et al., 2014) is used to calculate CDNC (cm^{-3}):

135
$$CDNC = \left(\frac{B}{CER} \right)^3 * \sqrt[3]{(2 * CLWP * \gamma_{eff})}$$

136 (1)

137 Where $B = \sqrt[3]{\left(\frac{3}{4}\pi\rho_{water}\right)} = 0.0620$, ρ_{water} is the liquid water density, γ_{eff} is the adiabatic
 138 gradient of liquid water content in the moist air column (Wood, 2006). Value of γ_{eff} range from 1
 139 to 2.5×10^{-3} at a temperature of 32 K to 104 K (Brenguier, 1991; Zhu et al., 2018; Zhou et al.,
 140 2020). The CLWP is estimated by use of

141
$$CLWP = \frac{5\rho_w(CER)(COT)_w}{9},$$

142 (2)

143 Where, ρ_w is the water density at room temperature (Koike et al., 2016).

144 National Center for Environmental Prediction/National Center for Atmospheric Research
 145 (NCEP/NCAR) reanalysis datasets provide global reanalysis data sets that combine satellite
 146 observations with the simulation of models through data assimilation (Purdy et al., 2016). Daily
 147 data for meteorological parameters including temperature, RH%, and ω at 850 hPa are retrieved at
 148 a spatial resolution of T62 Gaussian grid ($1.915^\circ \times 1.875^\circ$) from NCEP reanalysis-II datasets, and
 149 used to calculate lower tropospheric stability (LTS) defined as (Li et al., 2017):

150
$$LTS = \theta_{700} - \theta_{1000}$$

151 (3)

152 where θ is the potential temperature and the subscripts denote the pressure levels of 700
 153 hPa and 1000 hPa.

154 The Tropical Rainfall Measuring Mission (TRMM) is the first Joint satellite mission between
 155 NASA America and National Space Development Agency (NASDA) Japan, utilizing the visible
 156 infrared and microwaves to measure the rain precipitation over tropical and subtropical regions.
 157 The main TRMM instruments that are used to measure rain precipitation are precipitation radar
 158 (PR) and TRMM Microwave Imager (TMI). Where PR is operating at a frequency of 13.8 GHz
 159 and TMI is a passive microwave radiometer consisting of nine channels. A calibrated data set
 160 TRMM-2B31 of TRMM Combined Instrument (TCI) for TRMM Multi-Satellite Precipitation
 161 Analysis (TMPA) is formed from an algorithm that uses TMI and PR. The product TMPA 3B42

162 gives the rain precipitation averages on a daily and sub-daily basis. In the current study, the data
 163 product TMPA or TRMM 3B42 is used for the retrieval of PR daily. The spatial resolution of
 164 TRMM 3B42 is $0.25^\circ \times 0.25^\circ$ and is available from the year 1998 to till date.

165 2.2.2. Methodology

166 The present study is designed to analyze and quantify the ACPI for PCs and NPCs in winter and
 167 summer under a variety of meteorological conditions. The daily mean data of each parameter for
 168 warm clouds are retrieved from the respective satellites and NCEP/NCAR reanalysis-II for each
 169 study site. Subsequently, the VLOOKUP function in Microsoft Excel is applied to filtering out
 170 counts where data is not available, searching for values of a parameter in the first column, and
 171 retrieving the values of other parameters in the same rows on the corresponding dates in a large
 172 dataset. The data are then segregated into two subsets for the summer and winter seasons. Based
 173 on precipitation data from TRMM, the subsets are further divided into precipitating and non-
 174 precipitating clouds.

175 The sensitivities of cloud parameters to CDNC are analyzed through the following formulation
 176 considered from previous studies (Zhou et al., 2020):

$$177 \frac{d\ln(COT)}{d\ln(CDNC)} = -\frac{d\ln(CER)}{d\ln(CDNC)} + \frac{d\ln(CLWP)}{d\ln(CDNC)} \quad (4)$$

178 In this study, the term on the left side of equation (3) is defined as total indirect aerosol effect
 179 (TIE), and the first and second terms on the right side of the equation are defined as the first indirect
 180 aerosol effect (FIE), *and second indirect effect (SIE), respectively*. Similarly, the sensitivity
 181 of CDNC to AOD is evaluated by employing the index of ACI:

$$182 \text{ACI}_{CDNC} = \frac{d\ln(CDNC)}{d\ln(AOD)} \quad (5)$$

183 The sensitivity of PR to CDNC is calculated from the following equation (Jung et al., 2012) :

$$184 S_0 = \left(-\frac{\partial \ln(PR)}{\partial \ln(CDNC)} \right)_{COT} \quad (6)$$

185 3. Results and Discussion

186 3.1. Regional and seasonal distribution of AOD

187 AOD is a commonly used proxy for aerosol concentration in the atmosphere and is analyzed here
188 (Fig. 2-3).

189 IGP characteristically exhibits a diverse and massive pool of aerosols due to its unique topography.
190 The western part of IGP is a coastal location and inlet for the westerly winds. Therefore, dry
191 regions and the Arabian Sea in the west contribute dust, sea salt, and water vapors to the region.
192 The Himalayas in the north act as barriers to the winds, leading to the trapping of aerosols over
193 the central part of IGP. Therefore, this region exhibits a high concentration of anthropogenic
194 aerosols. The Bay of Bengal in the east allows southeasterly winds to enter passing across Dhaka,
195 Kolkata, and Patna to Delhi and Lahore (Hassan et al., 2002; Anwar et al., 2022). The westerly
196 and easterly winds traverse forested hilly terrain, rivers, and lakes elevating humidity levels and
197 initiating the cloud formation by activation of the newly originated small aerosol particles as CCNs
198 and cloud formation affecting the local microclimate.

199 Fig. 2 shows a decadal variation in time average maps for combined dark target and deep blue
200 AOD retrieved at $0.55 \mu\text{m}$ over the entire study area for the years (2001-2010) and (2011-2021).
201 Also, Table 1 illustrates the percentage change in decadal averaged values of AOD. The results
202 indicate that AOD exhibits a decrease over Karachi (-1.9%) and Jaipur (-0.5%). An increase in
203 AOD is observed over Lahore (5.2%), Delhi (9%), Kanpur (10.7%) and Gandhi College (22.7%).
204 Similarly, Table 1S shows the decadal change in AOD over Kolkata (18%), Dhaka (22.6%), and
205 Patna (23.3%). Similar to Gandhi College, an increase is observed over all three areas. Reasons
206 for the increase of aerosols include multiple sources of aerosols, human behavior, socio-economic
207 development at local and regional levels, and unique topography for the persistence and retaining
208 of aerosols.

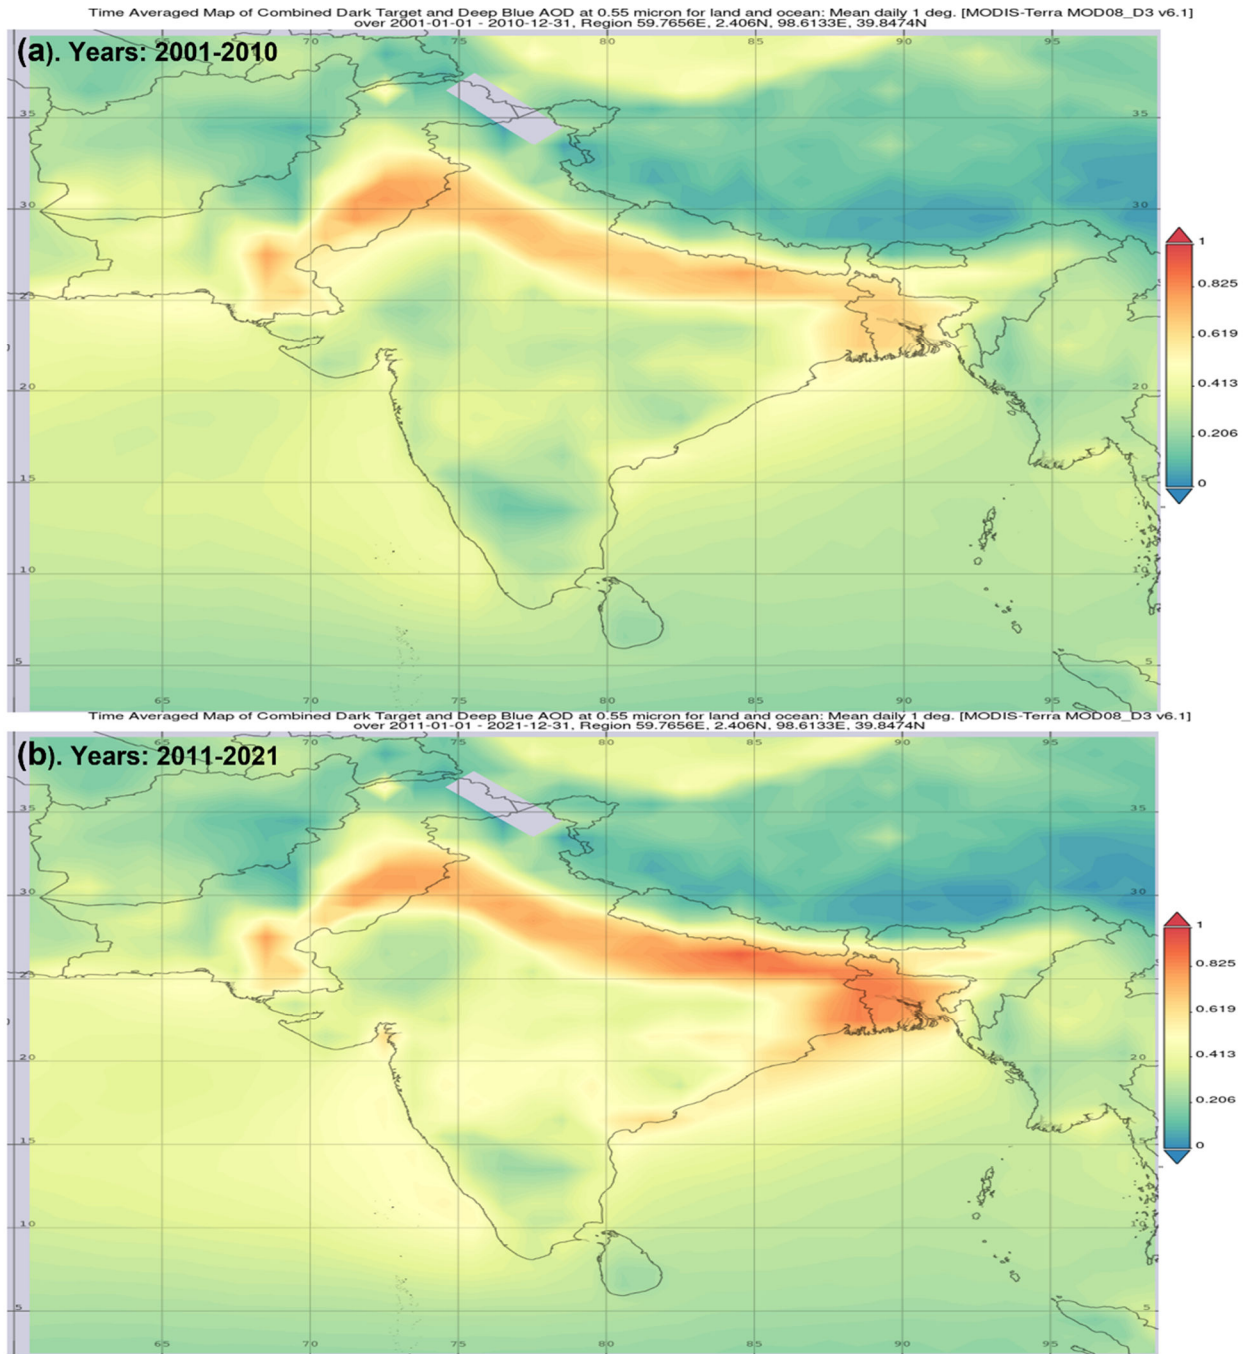

209 Fig.3(a-b) shows the probability density function (PDF) for AOD, illustrating different
210 distributions in the summer and winter seasons. Fig.3a shows that the distribution of AOD over
211 Delhi, Kanpur, and Gandhi College is similar. However, a shift in the peak value of PDF towards
212 high values of AOD over Lahore and low values over Jaipur illustrate comparatively high and low
213 aerosol concentration in the summer season over Lahore and Jaipur respectively. Likewise, Fig.

214 1S shows the seasonal PDF values of AOD over Kolkata, Dhaka, and Patna. The results indicate
215 similar seasonal distribution functions over all three areas of eastern IGP. In both seasons PDF
216 peaks for high values of AOD are observed over Patna showing a high concentration of aerosols
217 as compared to Kolkata and Dhaka.

218 The loading of high concentrations of aerosols is owing to the high density of population,
219 industrialization, and human activities. The major sources of aerosols in all months of the year
220 include vehicular emission originating from old transport facilities, emission of smoke and soot
221 during consumption of biomass for cooking, heavy industrial emission, and aerosols produced in
222 seasonal harvesting and crop residue burning. All these sources produce organic aerosols which
223 are characterized as hydrophilic particles and have the potential to act as CCN. Likewise, the soil
224 dust particles also act as good CCN due to their hydroscopic nature (Sun & Ariya, 2006).
225 Moreover, the meteorological conditions also play a substantial role in enhancing AOD values
226 such as the uplifting of loose soil dust and swelling of aerosols due to holding the water vapors
227 (wv) for a long time (Masmoudi et al., 2003; Alam et al., 2010; Alam et al., 2011;). Also, the lower
228 but flat PDF curve demonstrates low values of AOD over Karachi. Ali et al., 2020 associated the
229 low AOD values over Karachi with the westerly and southwesterly wind currents at tropospheric
230 level. However, the decreasing trend in AOD over the coastal city may also be attributed to the
231 variations in other meteorological parameters like T and RH.

232 As compared to the summer season, the pattern of PDF in winter is significantly different as shown
233 in Fig. 3b. The low value of PDF (0.5) for the high value of AOD (0.9) over Karachi illustrates a
234 comparatively pristine atmosphere. Similarly, the PDF peaks for Lahore, Delhi, and Jaipur (0.7,
235 0.7, and 0.8) indicate comparatively high AOD over Delhi. Likewise, the distribution over Kanpur
236 and Gandhi College similarly illustrates similar values of AOD (1.1 and 1.2 respectively). These
237 high values of AOD are attributed to the high emission of anthropogenic aerosols at local and
238 regional levels over the central part of IGP (Delhi, Jaipur, Kanpur and Gandhi College).

239 Few authors attributed the reduced values of AOD in the winter season to the wet scavenging and
240 suppressed emission of aerosols from the earth surface (Alam et al., 2010; Zeb et al., 2019).
241 However, in our case, the low (high) values in winter (summer) are associated with the dispersion
242 of fine (course) mode particles due to the variations in meteorological conditions.

	Karachi	Lahore	Delhi	Kanpur	Jaipur	Gandhi College
Total number of counts	5902	6171	5823	5201	5907	5125
Decadal change in AOD	-1.9%	5.2%	9%	10.7%	-0.5%	22.7%

250

251

252 **Figure 3.** The probability density function (PDF) of AOD over study sites is shown (a) and (b) for the summer and
 253 winter seasons respectively.

254 **3.2. Climatology of meteorological parameters**

255 Generally, LTS has relationships to factors such as temperature, humidity, wind patterns, and
 256 atmospheric pressure over extended periods. It is also widely acknowledged that atmospheric
 257 stability, temperature, RH wind speed, and direction play a significant role in cloud formation
 258 (Yang et al., 2015; Tao et al., 2012). Therefore, the influence of long-term variations in the said
 259 meteorological parameters is considered in the current study. The variations in meteorological
 260 parameters have an unavoidable impact on ACPI. The parameters considered in this study include
 261 the temperature, LTS to determine the lower atmospheric stability and instability that influence the
 262 process of cloud and precipitation formation through its significant implications on evaporation
 263 and convection of the air parcel, the RH% to estimate the level of wv and the ω to assess the
 264 suitable atmospheric dynamics. Fig.4 shows the variations in LTS values for NPCs and PCs in the
 265 winter and summer seasons. In the winter season, the LTS values are high for NPCs and
 266 comparatively lower for PCs over entire study areas. In the summer season, the scenario is reversed
 267 with high values for PCs but low values for NPCs, suggesting a stable tropospheric layer on rainy

268 days. This stabilization may be attributed to the cold pools generated by the evaporation of falling
269 rain droplets (Wu et al., 2017). The lower LTS values for NPCs in the summer season suggest the
270 likelihood of stronger instability that causes a high potential for vertical motion and the
271 development of thunderstorms. However, Karachi exhibits a distinct pattern of LTS with the
272 highest values in each case, which indicates the existence of the most stable tropospheric layer in
273 Karachi due likely to moist and cold sea breeze due to the city's coastal location.

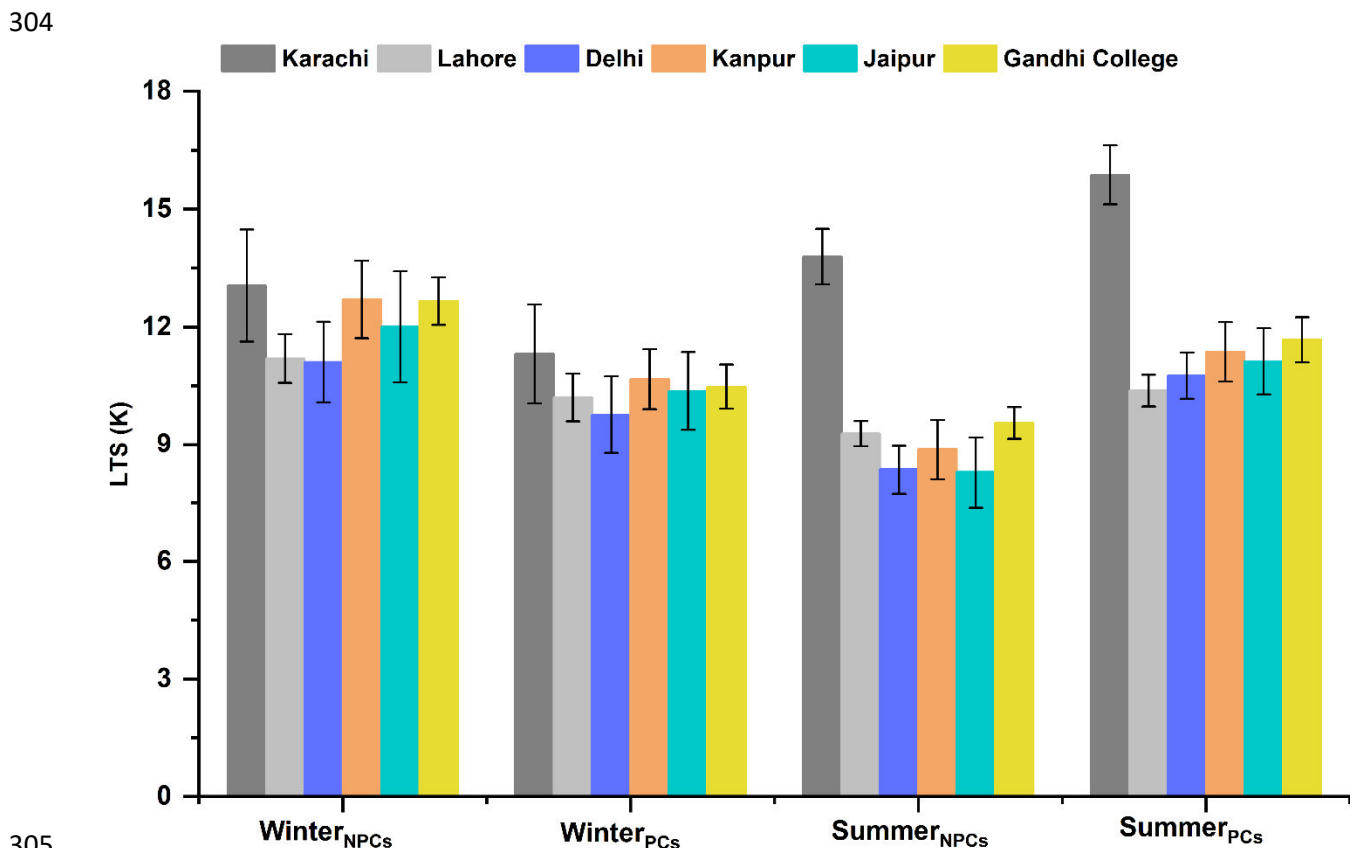

274 The median values computed for the remaining meteorological parameters considered in this study
275 are listed in Table 2. The high values in each case are indicated in bold and the low values are
276 italicized. The results show that in the winter season, the temperature at 850 hPa (T_{850}) is relatively
277 high for NPCs ranging from 281 K to 285.6 K. The increase in RH% for PCs during winter ranged
278 from (59.5)% to (71.5)%. Also, the $\omega > 0$ for NPCs and < 0 for PCs in the winter season.

279 In the summer season, it is observed that T_{850} is comparatively higher than that for the winter
280 clouds and ranges from 298.3 to 300.2 K and 296.5 to 298.3 K for NPCs and PCs respectively.
281 The high values of T_{850} are due to intense solar fluxes in the summer season that keep the
282 temperature of the earth's surface and adjacent atmospheric layer higher. Also, the increase in
283 RH% during summer ranged between 33.5-51.7 % for NPCs. The reason for the high values of wv
284 and RH% is mainly the suitable thermodynamical conditions such as evaporation and convection
285 due to the high temperature of the earth's surface and air (Sherwood et al., 2010). The results show
286 high values of RH% 70.1% (85%) in the winter (summer) season for PCs over Gandhi College.
287 Conversely, notable fluctuations in RH% are observed over the coastal city, of Karachi, with values
288 of 71.5% (65.9%) in winter (summer). Similarly, Fig. 2S and Table 2S show the LTS conditions
289 for PCs and NPCs. The high LTS values indicate more stable conditions over Dhaka. Similarly,
290 Table 2S shows the seasonal average values for other meteorological parameters. The results
291 indicate high values of T_{850} , RH%, and ω 295.5 (297.5) K, 88.8 (83.5)%, and -0.19 (-0.17) m/s
292 respectively for PCs (NPCs) for over Patna in summer.

293 Besides, during the last two decades, the wv and fog over the Arabian Sea increased (Verma et al.,
294 2022). Therefore, the high values of wv and RH% in summer months are due to the high-speed
295 zonal winds that blow in the summer season and transport water vapors and sea salt from the
296 surface of the Arabian Sea and hydrophilic aerosols such as soil dust from deserts of Iran, Pakistan,
297 and India to IGP. Moreover, during the winter season, elevated humidity levels are noticeable over

298 IGP, particularly in the vicinity of Gandhi College. This increased humidity is a result of
 299 evapotranspiration driven by agricultural practices, irrigation, the presence of rivers and lakes, and
 300 the introduction of moist, cold air from western winds (Nair et al., 2020). Where $\omega < 0$ for PCs
 301 over all study areas except Karachi.

302 The distinct variations in meteorological parameters reveal the occurrence of clouds with diverse
 303 properties. The detailed analysis of such clouds is given in the next subsections.

305
 306 **Figure 4.** Variations in lower tropospheric stability (LTS) over all study sites for PCs and NPCs in winter and summer
 307 seasons, the error bars show the standard deviation (SD) values.

308 **Table 2.** Median values of meteorological parameters for PCs(NPCs) in summer and winter seasons. Maximum values are for both types of
 309 clouds shown in bold and minimum values are indicated in italics.

	Winter Season			Summer Season		
	T ₈₅₀ (K)	RH%	ω (m/s)	T ₈₅₀ (K)	RH%	ω (m/s)
Karachi	284.6 (285.8)	71.5 (38)	-0.038 (<i>0.030</i>)	295.9 (298.8)	65.9 (45.9)	<i>0.005</i> (-0.003)

3.3. Regional and seasonal distribution of clouds and precipitations

3.3.1. Regional and seasonal differences in cloud occurrence and its microphysical structure

Fig.5 shows the frequency of occurrence of precipitable clouds and the total number of cloudy days. Chen et al. (2018) suggested the COT to be an effective measure for assessing the clouds and potential for precipitation. In our case, to avoid any overestimation, the COT data are aligned with PR data on corresponding dates and then filtered to include $COT \sim > 5$ for PCs. The results show that in the winter season, the frequency of clouds is low over Karachi and high over Lahore and Gandhi College. The results suggest the high number of PCs only over Lahore. In the summer season, a high number i.e., 74 % of the total data counts over Gandhi College are identified as cloudy days, 60 % of which are PCs. Similarly, most of the clouds over Lahore, Delhi, and Jaipur are PCs. Conversely, the least number of PCs (6 %) are found over Karachi. Likewise, Fig. 3S shows the total number of cloudy days and the number of days on which PCs occurred. The high occurrence of clouds is observed over Kolkata 83% (60%) and Dhaka 91% (69%) in the summer (winter) season. The high occurrence of PCs in summer is due likely to the significant impact of elevated aerosols with the southwesterly winds on the summer monsoons and the occurrence of PCs. Therefore, Kolkata and Dhaka are of critical importance from the perspective of aerosol loading and ACI (Dahal et al., 2022).

333

335

336

Figure 5. The frequency of occurrence of total cloudy days (including PCs and NPCs) and only PCs is shown for both winter and summer seasons.

337 Table 3 shows the criteria adopted from previous papers (Rossow & Schiffer, 1999; Wyant et
338 al., 2006; Sharma et al., 2023) for further classification of NPCs and PCs into different types
339 of clouds. The aim of identifying the cloud types is to assess the cloud regimes and their vertical
340 structure for a better understanding of ACPI. Following table 3, Fig. 6 shows joint histograms
341 of COT-CTP displaying the median values of CF for nine different types of clouds. For a quick
342 visual comparison, the cloud types are ordered from low to high-level clouds. Also, for each
343 histogram, the bins of COT and CTP are located on the x- and y-axis respectively. The CF of
344 each bin is represented with the colored bar with its value mentioned in the histograms as shown
345 in Fig. 6.

346 The results exhibit noticeable differences in the pattern of cloud regimes over all study areas.
347 The diverse CF values are observed in the winter and summer seasons for NPCs and PCs over
348 Karachi. In the winter season, only stratus NPCs ($23 < \text{COT} < 60$, $800 > \text{CTP} > 680$ hPa) are
349 dominant with $\text{CF} \sim 0.9$. While, in summers, the high value of $\text{CF} \sim 0.9$ for low and
350 intermediate thickness of high-level clouds such as Cirr-Stratus NPCs ($3.6 < \text{COT} < 23$, $180 <$
351 $\text{CTP} < 440$ hPa) are observed. Similarly, the types of PCs in both summer and winter seasons
352 that occurred with $\text{CF} \sim 1.0$ include cirrus and cirrus-stratus. The relatively reduced value of CF
353 for thick NPCs in winter and PCs in summer is attributed to the low values of AOD and high
354 values of LTS. The results depicted slight differences and similarities in CF values for thick
355 and thin NPCs respectively in the winter season for all areas except Karachi. Besides, the high-
356 level PCs are identified in the two bins of CTP ($180 < \text{CTP} < 440$ hPa) and ($440 < \text{CTP} < 680$
357 hPa) over all study areas. The formation of these similar types of PCs in winter is associated
358 with the similarities in ω , LTS values, and aerosol concentration.

359 Likewise, in the summer season, the matrices of PCs and NPCs exhibit a wide range of cloud
360 types. However, the CF values are comparatively high for PCs. Most of the identified PCs are
361 formed in the two bins of CTP ($180 < \text{CTP} < 440$ hPa) and ($440 < \text{CTP} < 680$ hPa) with CF
362 values ranging from 0.8 to 1.0. The results suggest low values of CF for the low-lying thick
363 NPCs over all study areas. Moreover, the results illustrate a more frequent occurrence of all
364 three types of thick NPCs in one bin of COT ($23 < \text{COT} < 60$) and all the three types of high-
365 level NPCs for CTP ($180 < \text{CTP} < 440$ hPa) over Delhi, Kanpur, and Gandhi College.
366 Therefore, these are considered the cloudiest regimes. Besides, contrasting regional variations
367 are also observed in PCs. The maximum CF values for all types of PCs are observed over
368 Kanpur and Gandhi College. Similarly, relatively good values of CF in a bin of COT ($23 <$

369 COT < 60) and a bin of CTP (180 < CTP < 440 hPa) over Lahore, Delhi, and Jaipur depict the
 370 frequent occurrence of thick and high-level PCs respectively. In addition, among all the
 371 estimated low-level PCs, cumulus and strato-cumulus exhibit good CF values (0.7) over
 372 Kanpur and Gandhi College. The formation of thick clouds can be attributed to the enhanced
 373 convection process due to atmospheric instability.

374

375 **Table 3.** Classification of clouds based on CTP – COT joint histograms.

CTP (hPa)	COT		
	0-3.6	3.6-23	23 to >60
440 to <180	Cirrus	Cirr-Stratus	Deep convection
680-440	Alto-Cumulus	Alto-Stratus	Nimbo-Stratus
<800 to 680	Cumulus	Strato-Cumulus	Stratus

376

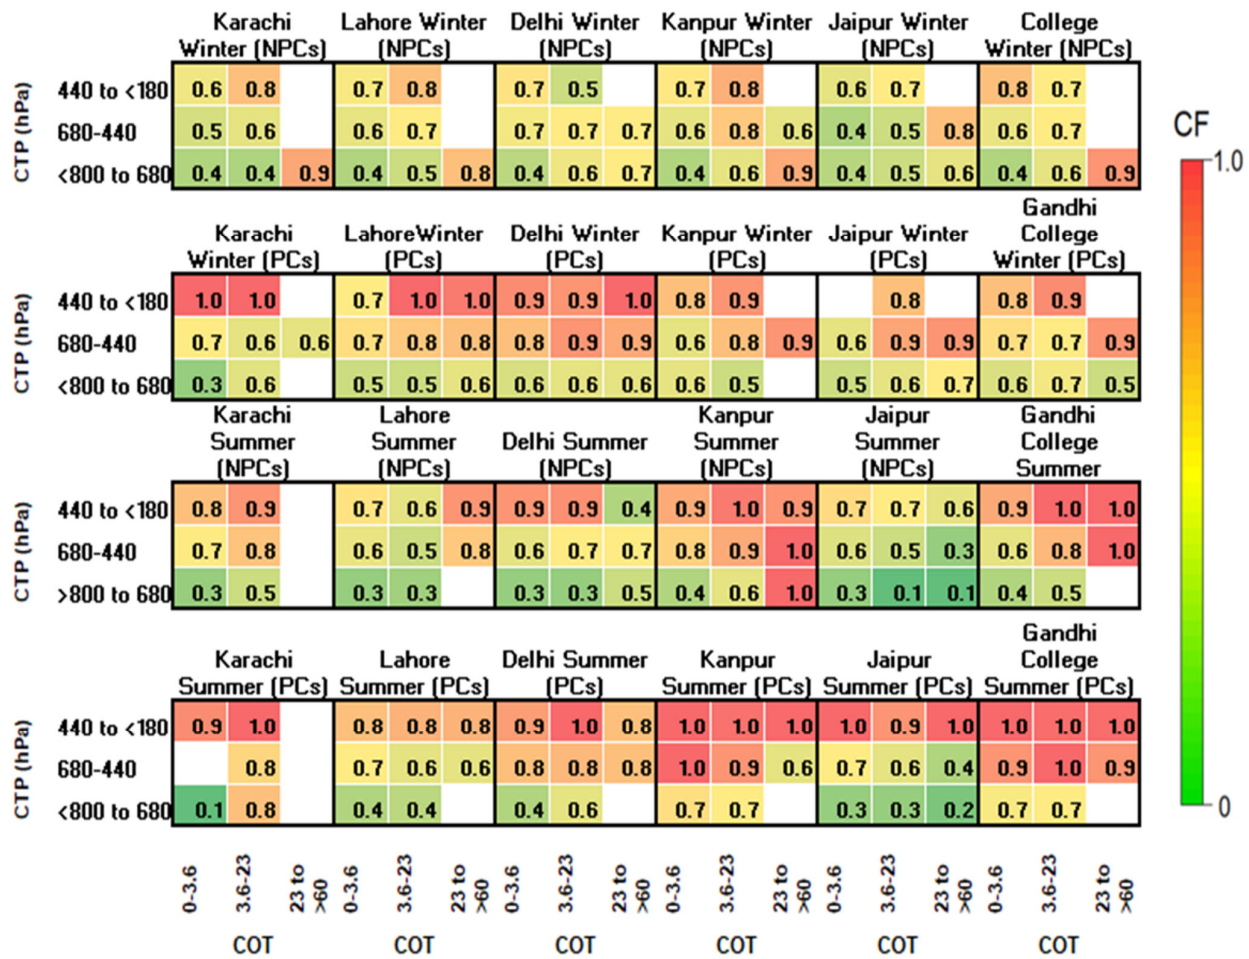

Figure 6. Types of NPCs and PCs in winter and summer season

377

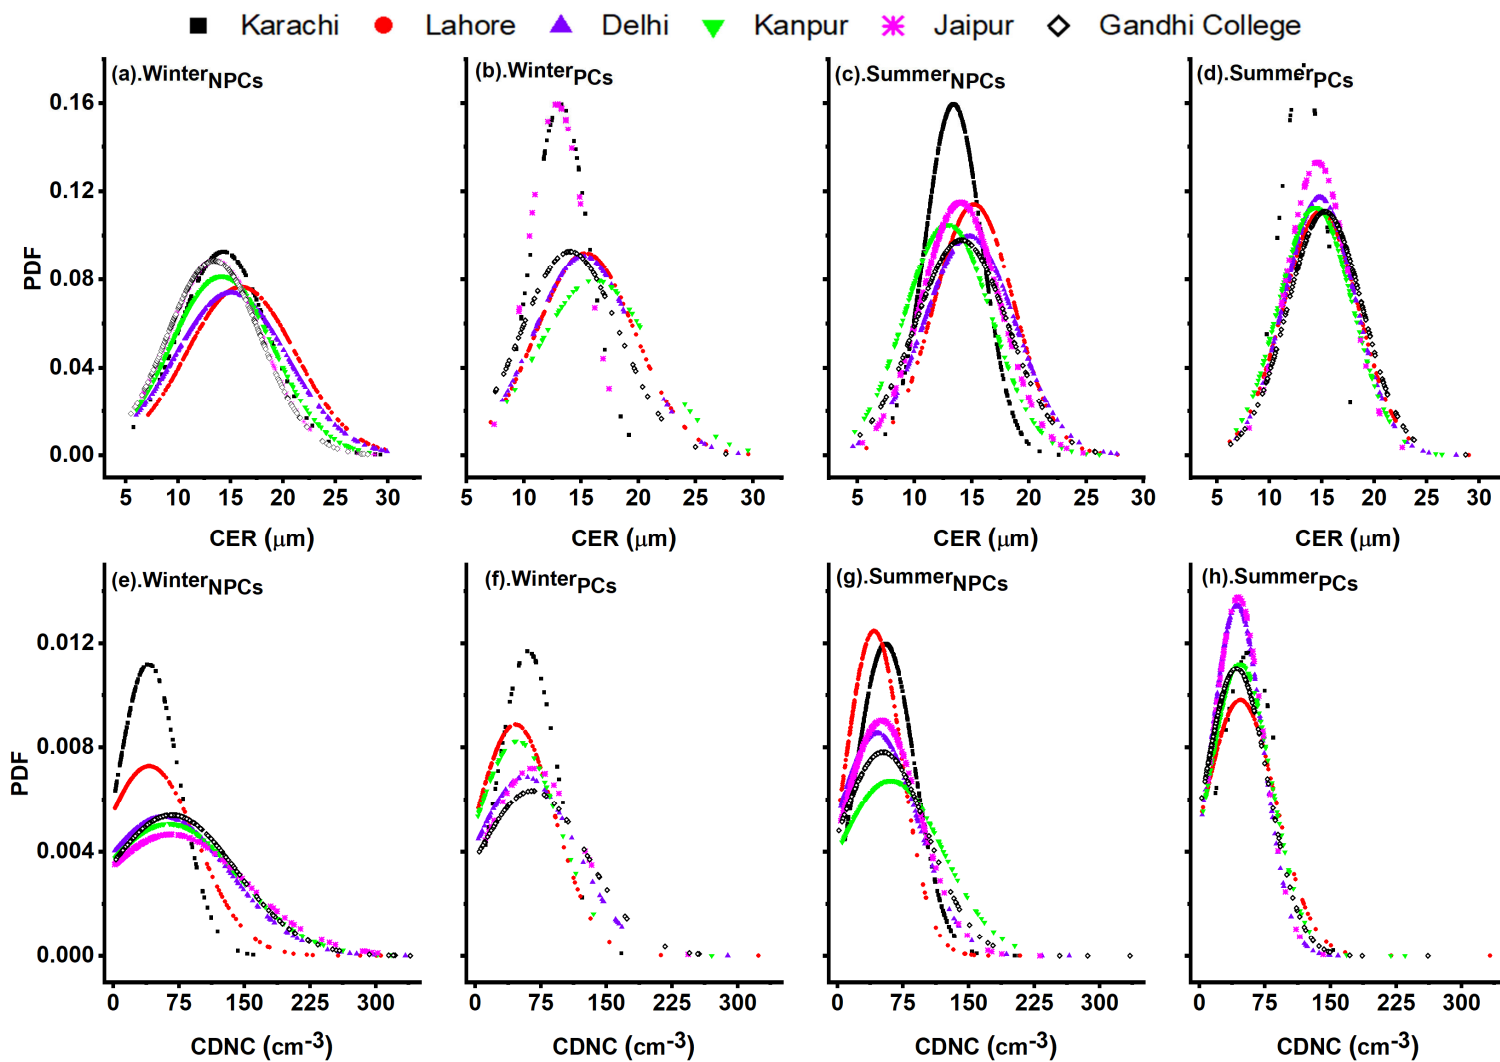

378

379 After estimating the cloud types, Fig. 7 shows the probability distribution function (PDF) of
380 cloud microphysical properties for the identification of differences in the microstructure of
381 NPCs and PCs in the summer and winter seasons. From the results, it is depicted an
382 approximately similar pattern for the CER of NPCs in winter. However, the clouds have high
383 peaks of PDF for lower values of CDNC over Karachi. The low number of CDNC results in
384 thin NPCs as shown in Fig.7. Similarly, Fig. 7(c and g) shows the microstructure of NPCs in
385 summer. The results indicate that as compared to CER values in winter, the probability of CER
386 $> \sim 15 \mu\text{m}$ is high in the summer season. However, the high peak for CER $< 15 \mu\text{m}$ is observed
387 over Karachi. Similarly, the CDNC shows a high probability for CDNC $> 50 \text{ cm}^{-3}$ with high
388 PDF values over Karachi. Where the lowest number of CDNC is observed over Lahore
389 indicating the formation of high-level thin NPCs in summer.

390 Fig. 7(b and f) shows the distribution pattern of CER and CDNC of PCs in the winter season.
391 It is observed that the distribution of CER for PCs is like that for NPCs in the winter season.
392 However, PDFs have peak values for relatively higher CDNC, which illustrates the occurrence
393 of thick clouds. Fig. 7(d and h) shows the variations in CER and CDNC in the summer season.
394 The results show a wider distribution for CER $> \sim 15 \mu\text{m}$ and higher peaks for CDNC $> \sim 50$
395 cm^{-3} suggesting the formation of thick PCs in summer as shown in Fig.6.

396

397

398

399

Figure 7. Probability density function (PDF) of precipitating (PCs) and non-precipitating clouds (NPCs) in the winter and summer season

400 **3.4. Aerosol-Cloud-Precipitation Interaction (ACPI)**

401 In the following sections, ACPI is analyzed and discussed in detail for PCs and NPCs in the
402 summer and winter seasons.

403 *3.4.1. Aerosol effects on cloud properties*

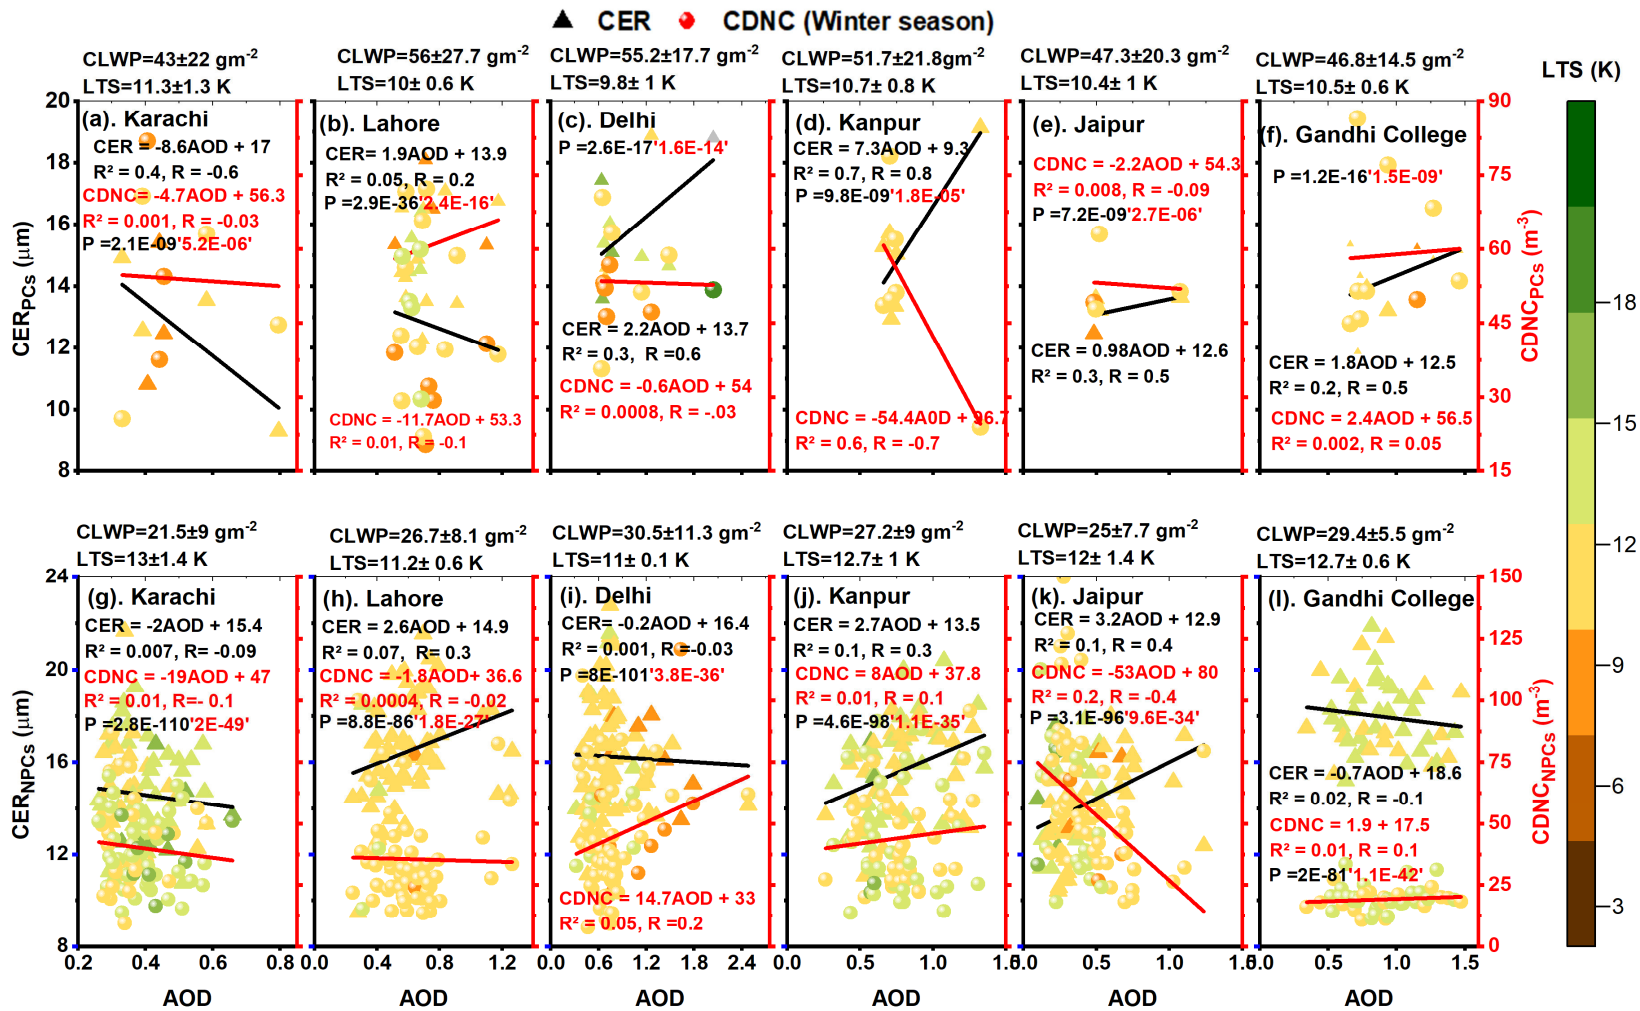

404 The impact of aerosols on CDNC and CER of PCs and NPCs is illustrated as scatter plots in
405 Fig. 8-9. The quantification of the AOD-CER and AOD-CDNC relationships is demonstrated
406 through detailed linear regressed slopes, regression coefficients (R^2), and Pearson's correlation
407 coefficient (R). The color bar represents the variations in LTS. The results show that the two-
408 sample student's t-test is carried out to analyze the AOD-CER and AOD-CDNC relationship in
409 view of statistics. The results illustrate that the relationships are statistically significant at a
410 95% ($p < 0.05$) significance level for all study areas. Fig.8 shows that in the winter season, the
411 AOD-CER correlation is good for PCs and weak for NPCs. The results also show that the LTS
412 values are higher for NPCs. The weak AOD-CER correlation may be linked to the inhibition
413 of droplet growth due to less soluble aerosols, originating from biomass burning (Kang et al.,
414 2015). In our case, all the selected study areas are among the most urbanized and industrialized
415 areas of IGP. Therefore, most of the prevailing aerosols are the less soluble soot and BC
416 particles. That weakened activation of cloud droplets inhibits the formation of PCs and
417 evaporates to higher altitudes thereby increasing the droplet residence time (Kumar & Physics,
418 2013). Besides, the results show a contrasting pattern of LTS values. Although RH over Karachi
419 ($38.3 \pm 9\%$) is higher than over the other study areas (shown in Table 2), the negative AOD-
420 CER correlation is observed over Karachi due to its coastal location, the low value of AOD and
421 high level of LTS.

422 Fig. 9 illustrates the AOD-CER and AOD-CDNC correlation in the summer season. The results
423 depict a more significant and positive AOD-CER correlation in the summer season than winter
424 season. Unlike the winter season, high LTS values are observed for PCs. Yuan(2008)
425 associated the positive AOD-CER correlation with the soluble organic aerosols. Myhre et al.
426 (2007) hypothesized that the positive AOD-CER correlation is a maximum for low CTP and a
427 minimum for high CTP. Hence, in our study, referring to the approximated CF values shown
428 in Fig.6, the significant and positive AOD-CER correlation under unstable atmospheric
429 conditions resulted in thick and high-level clouds. Furthermore, it is observed that CER and
430 CDNC values for NPCs increase with increasing instability. Meanwhile, the enhanced process
431 of droplet activation may result in large AOD, higher CER, giant, and fewer CCN (Yuan, 2008).

432 Therefore, the weak correlation of AOD with CER and CDNC may be due to the
433 anthropogenically ejected water-soluble organic aerosols and a smaller number of CCN.

434 Fig. 5S and 6S show the impact of AOD on CER and CDNC for PCs and NPCs in winter and
435 summer respectively. The results indicate a positive and weak AOD-CER correlation of 0.2,
436 0.07, and 0.004 for NPCs over Kolkata, Dhaka, and Patna respectively, and for PCs (0.08) over
437 both Kolkata and Patna. Similarly, a positive and weak AOD-CDNC is observed over all areas
438 for PCs. Likewise, Fig. 6S also illustrates weak AOD-CER correlation is 0.06, 0.2, and 0.12
439 for both types of clouds in summer. As compared to other areas, the correlation analysis is less
440 significant over Karachi, Kolkata, Dhaka, and Patna. This can be attributed to the persistence
441 of diverse aerosol types influenced by their coastal locations, different meteorology, and the
442 alternating inflow and outflow of easterly and westerly winds.

443 Recent advances in remote sensing led to cost-effective solutions and an increase in available
444 data at various temporal and spatial resolutions to bridge scientific gaps among different
445 disciplines. While satellite-based retrievals have many advantages over in-situ and ground-
446 based measurement such as broader regional coverage and enhanced spatial resolution, they
447 are still prone to considerable uncertainties owing to the indirect nature of remote-sensing,
448 retrieval algorithms, thermal radiance, infrequency of satellite overpasses, and cloud top
449 reflectance (Hong et al., 2006; Tian et al., 2010; Hossain et al., 2006). In our study, apart from
450 the aforementioned factors contributing to the uncertainty, any residual cloud contamination
451 could also lead to biased retrieval of AOD. Likewise, satellite-based retrievals for cloud
452 properties are crucial to understanding the pivotal role of clouds in climate and the role of
453 clouds is still a dominant source of uncertainty in the prediction of climate change. These,
454 uncertainties in AOD and retrievals of cloud properties also propagate through the modeling
455 process, potentially leading to less accurate climate predictions. Likewise, these uncertainties
456 appeared to influence the findings in the current investigation. For instance, a limited
457 correlation between AOD and CER is observed over Lahore, particularly in cloudier regimes
458 as depicted in Fig. (5-6). This contrasts with robust impacts documented in earlier studies
459 (Michibata et al., 2014). However, high sensitivity of SIE is observed for PCs particularly in
460 the winter season indicating the delay in the onset of precipitation and more retention of clouds.

461

462

463

Figure 8. AOD-CER and AOD-CDNC regression and correlation coefficient considered at 95% confidence level for PCs and NPCs over all study areas in the winter season.

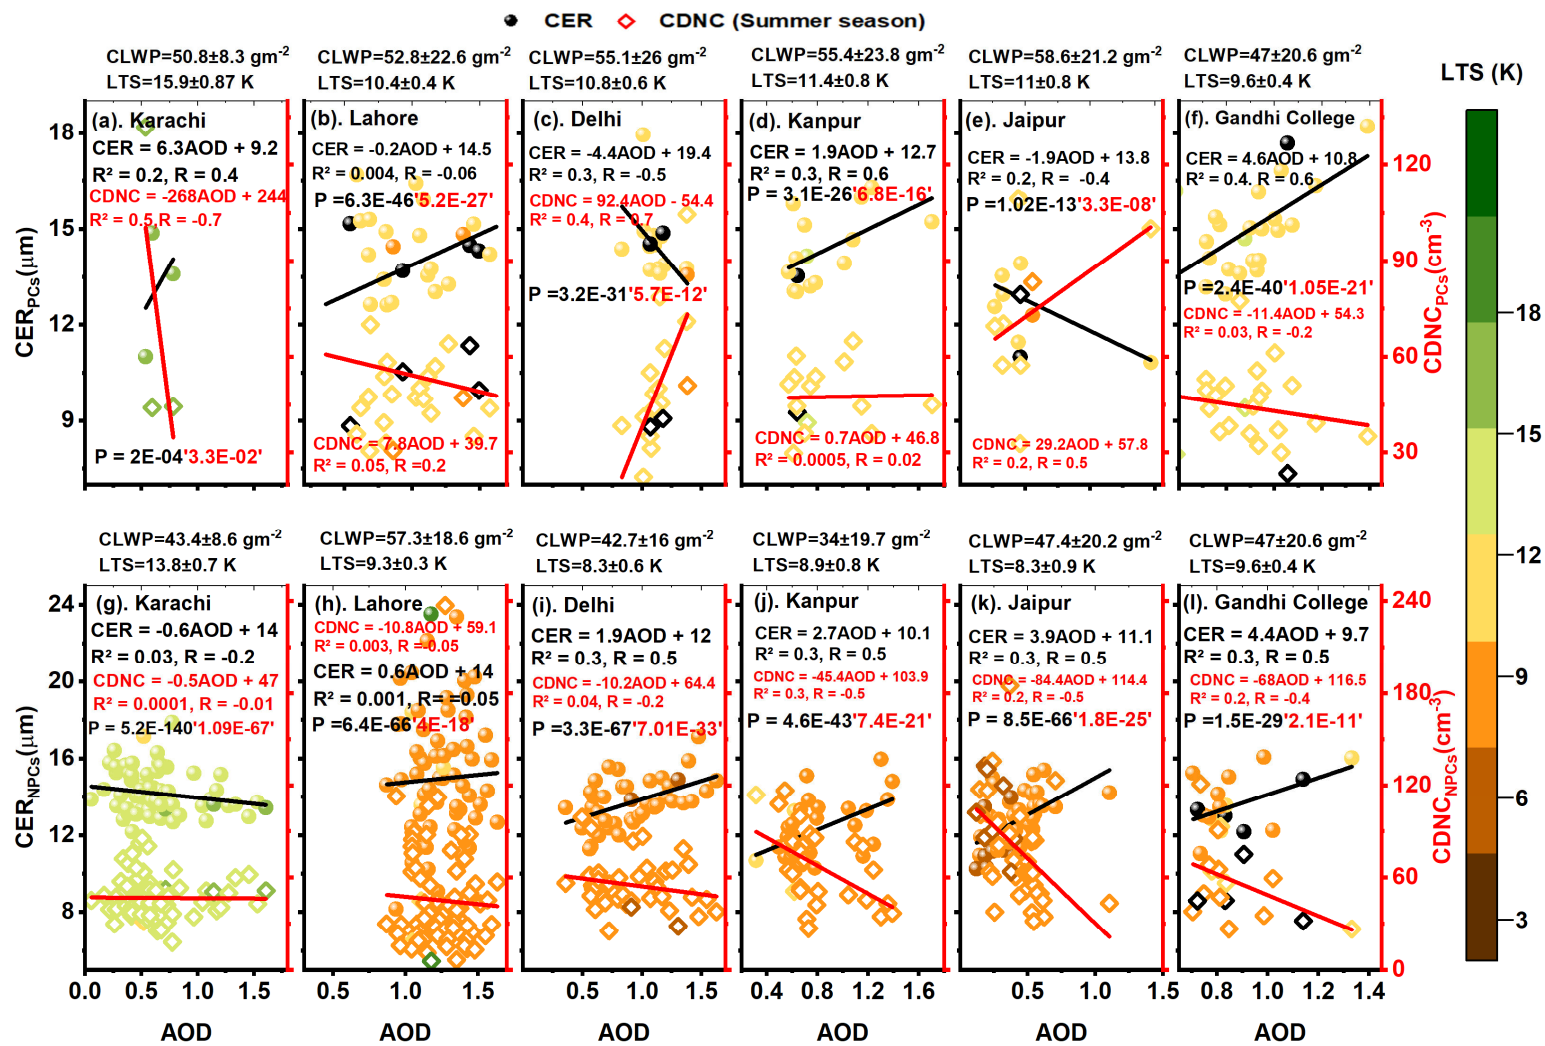

Figure 9. Same as Fig. 8 but in the summer season.

464

465

3.4.2. Seasonal variations in sensitivities of aerosol-cloud indirect effects and ACI

466
467 Fig.10 shows an assessment of four ACI sensitivities in terms of CDNC using daily mean
468 values of MODIS observations available over the entire study area. Studying the effects of
469 aerosols on the co-located clouds is a challenging task due to the overestimation of thin clouds
470 in AOD retrievals. Therefore, to minimize the propagation of AOD retrieval errors in ACI, the
471 current study attempted to estimate the sensitivities of different cloud mechanisms to CDNC.

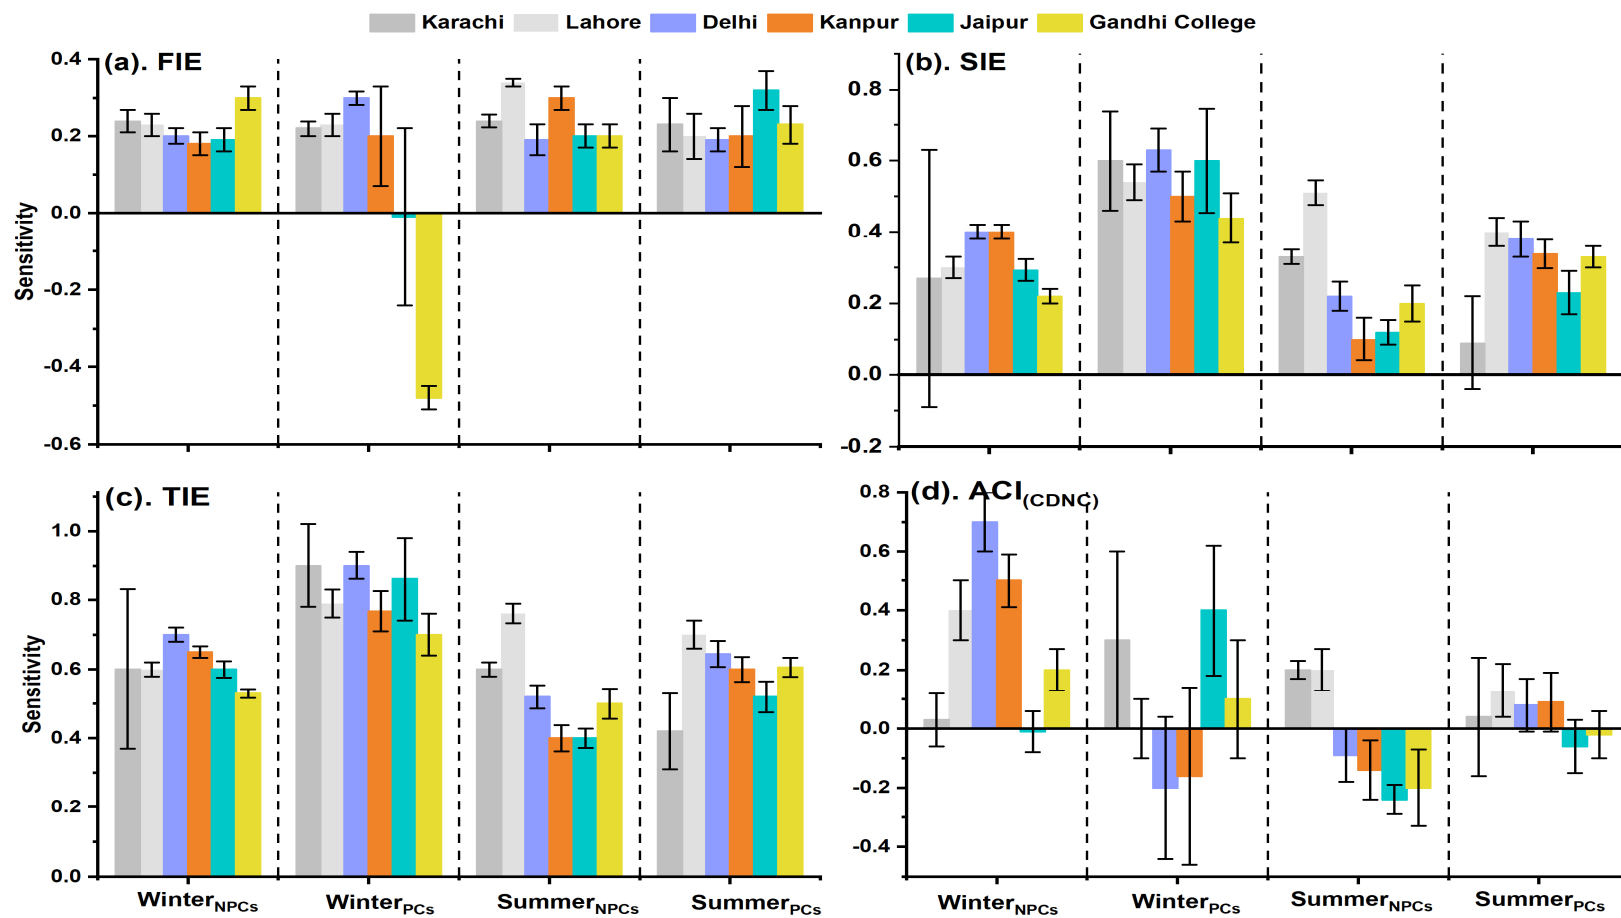

472 The sensitivity of CER to CDNC is assessed as a signature of FIE as shown in Fig.10a. The
473 positive values illustrate that CER decreases with an increase in CDNC revealing the
474 occurrence of the Twomey effect. While the negative values depict the anti-Twomey effect.
475 Tripathi et al., (2007) divided IGP into four regions western, central, eastern part of IGP, and
476 the foothills of the Himalayas. Their results depicted a high concentration of dust in the western
477 part, and an increase in anthropogenic aerosols as one moves from the western to the eastern
478 part of IGP. Therefore, they attributed the resulting strong indirect effect in winter to the high
479 concentration of regional anthropogenic pollution. However, in our case, the FIE is investigated
480 for both PCs and NPCs in both seasons. The resulting approximations in the winter season
481 show strong (weak) sensitivity of FIE for PCs (NPCs). Similarly, the estimated sensitivity of
482 FIE for all NPCs and PCs is also positive in the summer season. Fig. 7S(a) shows sensitivities
483 for FIE in both seasons for PCs and NPCs. The results indicate high values of sensitivity FIE
484 in the winter season which is similar to the results for Karachi, Lahore, Delhi, and Kanpur as
485 shown in Fig. 10 a. This is attributed to high levels of aerosol emission from residential heating
486 and industrial activities. Furthermore, the results illustrate higher values of FIE in summer. This
487 is attributed to the massive aerosol loading due to aerosol carried by winds and originating
488 from anthropogenic activities and unstable meteorology.

489 Fig. 10b illustrates the sensitivity of CLWP to CDNC as a proxy for the evaluation of the SIE
490 or lifetime effect. The positive sensitivity estimated for all NPCs and PCs suggested that the
491 CLWP increases with an increase in aerosol. Further, the results show that the sensitivity of
492 SIE is stronger for PCs in winter which indicates the delay in the onset of high PR. Similarly,
493 the results show that the SIE sensitivity values are higher for PCs than for NPCs in the
494 corresponding seasons. Therefore, the results depict that the lifetime of PCs is greater than
495 NPCs. This is attributed to the high level of RH for PCs as shown in Table 2. Fig. 10 (a and b)
496 shows that the FIE sensitivities are weaker than SIE.

497 Fig. 10c shows the TIE in terms of the sensitivity of COT to CDNC. The results illustrate
498 positive values of sensitivity for all NPCs and PCs which indicate that COT increases with an
499 increase in aerosol concentration. The results also reveal that the sensitivity of TIE is a linear
500 sum of the sensitivities of FIE and SIE. Further, the results also suggest that the variations in
501 TIE sensitivity are largely dependent on SIE.

502 Fig.10d shows the sensitivity of CDNC to AOD as an estimation of ACI in terms of CDNC.
503 The positive values show the increase in CDNC with the increase in AOD. Therefore, positive
504 ACI reflects the inhibition of precipitation formation. Whilst, the negative values illustrate the
505 decrease in CDNC and enhanced PR (Fan et al., 2018). The results depicted relatively large
506 and positive sensitivities for NPCs in winter over Lahore, Delhi, and Kanpur, which inhibits
507 the onset of rainfall. The Sensitivity of ACI for NPCs in summer is positive over Karachi and
508 Lahore and negative over Delhi, Kanpur, Jaipur, and Gandhi College. Ackerman et al. (2004)
509 associated the negative ACI_{CDNC} with the wet scavenging and mixing of air by entrainment.
510 In our case, negative ACI may be due to the growth of CER and a decrease in CDNC with
511 aerosol loading under unstable conditions (shown in Fig. 9). Further, the magnitude of
512 sensitivity for PCs in summer is low. This can be due to the droplet growth through collision
513 coalescence and wet scavenging in thick clouds, decreased dependency on CCN.

514

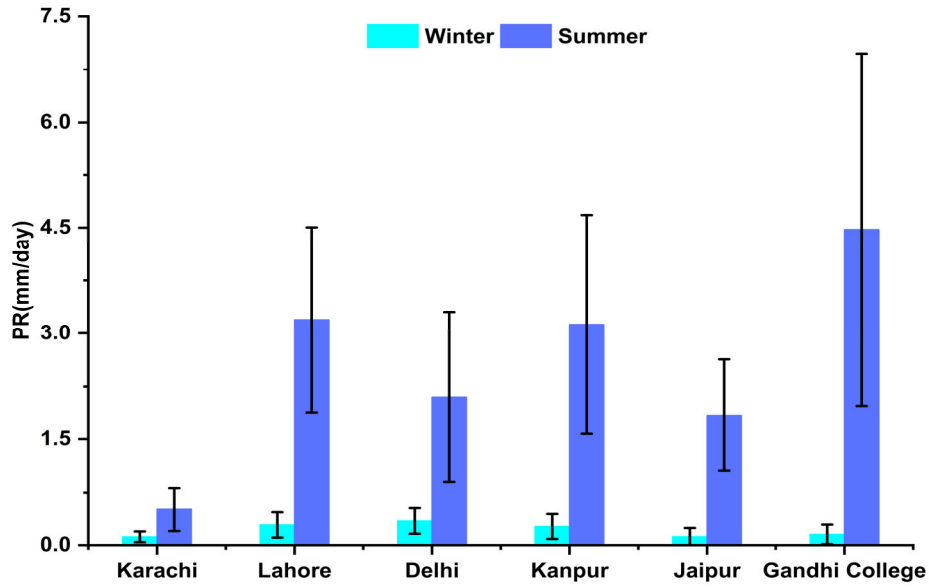

516

517 **Fig. 10.** The sensitivity matrices estimated for an aerosol-cloud relationship using CDNC are shown in (a) $FIE = -\left(\frac{\partial \ln(CER)}{\partial \ln(CDNC)}\right)$ (b) $SIE = \left(\frac{\partial \ln(cLWP)}{\partial \ln(CDNC)}\right)$,
 518 (c) $TIE = \left(\frac{\partial \ln(COT)}{\partial \ln(CDNC)}\right)$ and (d) $ACI = \left(\frac{\partial \ln(CDNC)}{\partial \ln(AOD)}\right)$. Where the error bars show the standard deviation (SD).

519 3.4.3. *Aerosol effects on precipitation*

520 Fig. 11 shows the average values of PR in mm/day retrieved from TRMM. The results show
521 an obvious seasonal difference in precipitation occurrence. The reason for the high (low) PR
522 values is due to the suitable meteorological conditions including high (low) LTS values for PCs
523 in the summer (winter) season (shown in Fig. 8-9). The stable atmospheric condition with a
524 high LTS value in winter serves to inhibit the convection process and have a significant impact
525 on controlling the PR in winter (Zhao et al., 2006). Conversely, during the summer season,
526 meteorological instability prevails with low LTS values which result in high RH. This not only
527 causes enhanced AOD due to the water uptake and results in swelled hydrophilic aerosols
528 (Alam et al., 2010; Alam et al., 2011) but also affects the cloud and precipitation formation due
529 to the enhanced evaporation and convection. Additionally, Fig. 8-9 also shows evidently and
530 specifically during summer that the possible cause of positive AOD-CER correlation is the
531 negative AOD-CDNC correlation under unstable meteorology over all areas except Karachi.
532 As a result, Fig. 11 shows high (low) values of PR over all areas with a maximum over Gandhi
533 College (Karachi). The results show a high (low) approximation of PR over Gandhi College
534 (Karachi). Knowing that the rate of conversion of CDNC to precipitation is proportional to
535 CER (Wolf & Toon, 2014). Therefore, the high PR values are due to the growth of bigger cloud
536 droplets in summer. Further, apart from the reasons mentioned in the preceding sections, the
537 other justification for the differently perturbed aerosols, clouds, and precipitation pattern over
538 the study areas in summer is due to the entrance of southeast winds from the Bay of Bengal
539 passing across Gandhi College to Delhi and Lahore and the entrance of same winds from
540 Arabian sea to Pakistan through Karachi (Anwar et al., 2022).

541 Fig. 12 shows scatter plots of PR versus CDNC. The plot is colored with COT to examine the
542 impact of CDNC on PR for similar macrophysics. When CDNC is less, then the COTs are
543 sparse grow larger, form less reflective clouds, and precipitate faster (Kump & Pollard, 2008).
544 The same phenomenon seems true in our case. The results illustrate high PR (0.0007 mm/day)
545 values for clouds with COT ranging from 3 to 28 with $CDNC < \sim 50 \text{ cm}^{-3}$ and intermediate for
546 optically thick clouds and $CDNC > \sim 50 \text{ cm}^{-3}$ in both seasons.

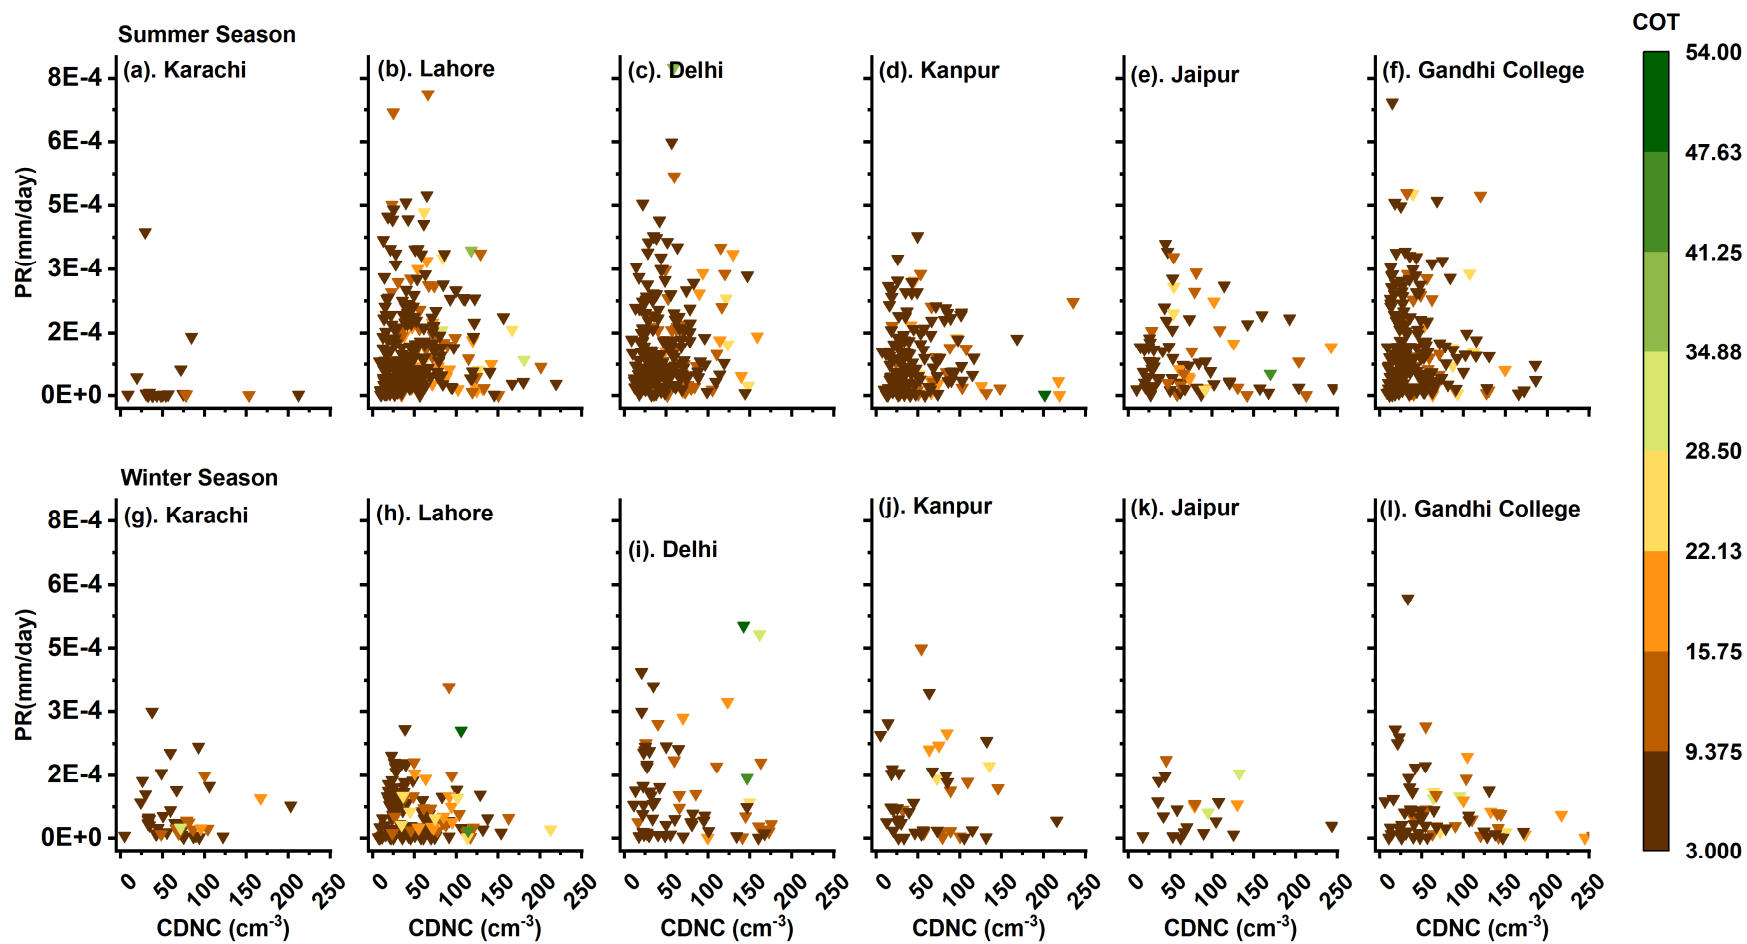

547

548

549

Figure 11. Mean Precipitation rate (PR) for the PCs in winter and summer season and SD values with a 95% confidence interval.

550

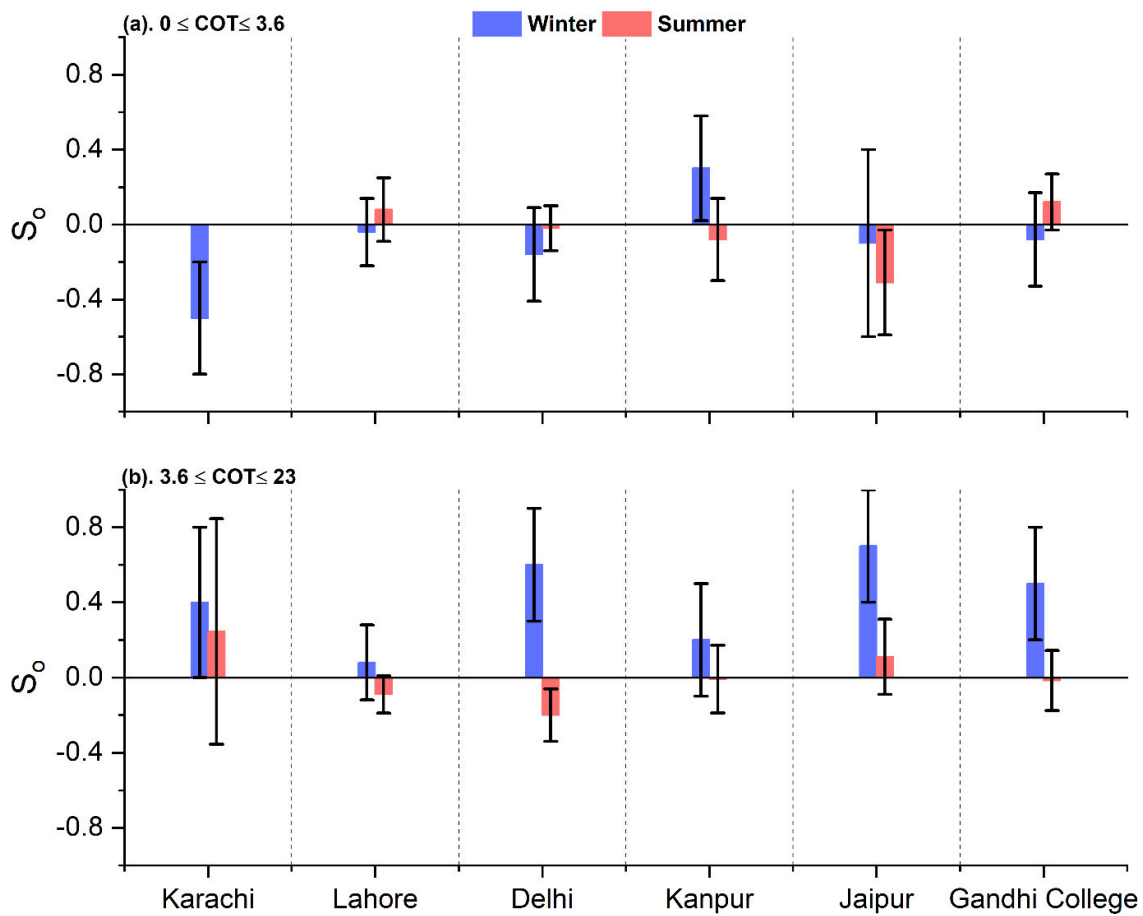

551

Figure 12. Scatter diagrams of PR (mm/day) versus CDNC (cm⁻³) in summer and winter seasons. color coding shows the COT of PCs.

552

553 Fig.13 shows the sensitivity (S_o) of PR to CDNC defined by $S_o = \left(-\frac{d\ln(PR)}{d\ln(CDNC)}\right)_{COT}$ for clouds
 554 of low and intermediate thickness illustrated in Fig. 13 a and Fig. 13 b respectively. However,
 555 sensitivity analysis for $COT > 23$ could not be performed due to the smaller number (0 to 04)
 556 of available samples. In the sensitivity equation, the minus sign shows the suppression of
 557 precipitation formation due to the increase in CDNC. Further, when S_o is positive, the
 558 correlation between PR and CDNC is negative; however, for negative S_o , PR and CDNC are
 559 positively correlated. The results show peak values of S_o i.e., 0.7 ± 0.3 , 0.6 ± 0.3 , 0.5 ± 0.3 , and
 560 0.4 ± 0.4 over Jaipur, Delhi, Gandhi College, and Karachi respectively at intermediate values
 561 of COT in winter, indicating the occurrence of lightly precipitating clouds. Referable to Fig.
 562 13b, the low magnitude of S_o 0.2 ± 0.3 and 0.08 ± 0.2 over Kanpur and Lahore respectively is
 563 due to coagulation, in which precipitations are less sensitive to CDNC.

564

565

566 **Figure 133.** The sensitivity ' S_o ' of precipitation rate (PR) for two bins of COT is shown in (a).
 567 $0 \leq COT \leq 3.6$ and (b). $3.6 \leq COT \leq 23$.

568

569 4. Conclusion

570 In this study, the long-term (2001-2021) data retrievals from MODIS coupled with TRMM and
571 NCEP/NCAR reanalysis-II datasets over the entire study area are compiled and analyzed for
572 PCs and NPCs in the winter and summer season. The following are the main findings of this
573 study.

574 A decadal decrease in AOD is observed over Karachi (-1.9%) and Jaipur (-0.5%). Meanwhile,
575 AOD exhibits an increase over Lahore (5.2%), Delhi (9%), Kanpur (10.7%) and Gandhi
576 College (22.7%). The LTS values are High (low) for NPCs (PCs) in winter and for PCs (NPCs)
577 in the summer season. However, among all study areas, Karachi exhibits comparatively high
578 LTS values in both seasons. Apart, the increase in RH% for PCs ranged from 33-57% in winter
579 and from 25-45 % in summer. $\omega > 0$ for all NPCs in winter and < 0 for PCs in both winter and
580 summer seasons.

581 In the winter season, a low frequency of cloudy days over Karachi and a high over Lahore and
582 Gandhi College is estimated. Also, the high number of PCs is estimated only over Lahore. In
583 the summer season, out of the 74 % of the cloudy days, 60 % are PCs over Gandhi College.
584 Similarly, most of the clouds over Lahore, Delhi, and Jaipur are PCs. Conversely, the lowest
585 number of PCs (6 %) is found over Karachi. The high-level PCs are identified in one bin of
586 CTP ($180 < \text{CTP} < 440$ hPa) over all study areas in winter. In the summer season, all three
587 types of high-level and thick PCs have significant values of CF. The low-level PCs are
588 identified as stratus clouds. Further, PDF values for CER $> \sim 15 \mu\text{m}$ and CDNC $> \sim 50 \text{ cm}^{-3}$
589 for NPCs and PCs are high (low) in summer (winter) over all areas except Karachi.

590 The AOD-CER correlation is good for PCs and weak for NPCs in the winter season. Also, the
591 CER and CDNC values increase with the increase in LTS. The sensitivity value of FIE is high
592 (low) for PCs (NPCs) in winter. Further, the magnitude of sensitivity of FIE (SIE) is low (high).
593 Also, the sensitivity of TIE is a linear sum of the sensitivities of FIE and SIE. Further, ACI
594 sensitivity values for PCs in summer are small, illustrating less dependency of CER on CDNC
595 in thick clouds.

596 The high (low) PR values are observed in summer (winter). Further, high PR values for
597 comparatively thin clouds with fewer CDNC $< \sim 50 \text{ cm}^{-3}$ and intermediate for optically thick
598 clouds and CDNC $> \sim 50 \text{ cm}^{-3}$ are observed. Sensitivity values are small (high) for thick clouds
599 in summer (winter).

600 Being one of the major source regions of anthropogenic aerosols across the globe, IGP
601 offers interesting insights into the study of ACPI coupled with aerosol indirect effects. This
602 study highlights that the aerosol-cloud relationship exhibits different behavior under
603 different meteorological conditions, at coastal and inland locations. Thus, compared to
604 other study areas, the stable atmospheric conditions due to the constant sea breeze
605 weakened the ACI over Karachi, which resulted in a smaller number of CDNC, NPCs, and
606 PCs. Further, our study also provides a very good platform for the detailed analysis of
607 sensitivity tests of aerosol indirect effects and precipitation formation.

608 **Limitations and future recommendations:**

609 Although the current study is as thorough as possible, however, it has its limitations due to
610 the topographical complexity of IGP, the lack of in-situ measuring instruments in Pakistan,
611 and the intrinsic uncertainties associated with satellite-based data. Therefore, simulations
612 of ground-based measurements along with satellite-based retrievals and calculation of
613 cloud properties and CCN by different Community Atmosphere Model (CAM) and
614 Weather Research and Forecasting (WRF) Models are recommended for deep insight into
615 the various mechanisms of ACPI over IGP.

616 **Data Availability:** The MODIS and TRMM data can be obtained from the NASA Goddard
617 Earth Sciences Data and Information Center (GES DISC) and can be retrieved from the
618 websites: <https://modis.gsfc.nasa.gov/data/> and <https://gpm.nasa.gov/data> . The reanalysis-
619 II datasets are obtained from the website:
620 <https://psl.noaa.gov/data/gridded/data.ncep.reanalysis2.html> . The processed data used in
621 this work are available on reasonable request from the corresponding author.

622 **Author contribution:** NG processed and analyzed the data and wrote the original draft of
623 the manuscript. KA proposed the Idea, supervised this work, and revised the manuscript.
624 YL helped in revising the manuscript.

625 **Acknowledgment:** The authors gratefully acknowledge the NASA Goddard Earth
626 Sciences Data and Information Services Center (GES DISC) for the provision of freely
627 available data retrieved from MODIS and TRMM. We are also grateful to the NOAA
628 Physical Sciences Laboratory (PSL) for free accessibility to (NCEP/NCAR) reanalysis-II
629 datasets.
