Text S1. The introduction of the steady-state six-compartment six-fugacity model

Multimedia fugacity models have been used to address chemical pollution by providing a quantitative account of the sources, transport processes, fate and sinks of organic chemicals(Mackay, 2001). A steady-state six-compartment (gas, particle, liquid, suspended particle mater (SPMs), soil, sediments) six-fugacity model was derived using the fugacity theory (Li et al., 2021b). The six-compartment six-fugacity system was exhibited in following figure. The subscripts represent different environment matrix: gas (G), liquid (L), soil (S), sediment (Sed), particle in air (P), and particle in liquid (O). The primary equation in fugacity models is the relationship between the flux (F) and the fugacity (f):

$$F = fD (S1)$$

59 where D is the intermedia D values defined in the fugacity theory (Mackay, 2001).

The six-compartment six-fugacity system

(Notes: E_i is the emission rate (mol/h) to compartment i; F_{ij} is the flux from compartment i to compartment j (mol/h); F_{iR} is the flux by reaction (mol/h); Particle represents particle in air; SPM represents suspended particle matter in water.)

The relationships between the above figure (focusing on the processes related to the six compartments) in Supporting Information and Fig.1 (focusing on the processes related to gas and particle phases) in the main text of the manuscript were described in detail as follows. For the gas phase, in the above figure, the flux of F_{GS} (flux from gas to soil) includes the diffusion flux from gas to soil (F_{GS_diff}) and the wet deposition flux from gas to soil (F_{GS_W}). The flux of F_{GL} (flux from gas to liquid) includes the diffusion flux from gas to soil (F_{GW_diff}) and the wet deposition flux from gas to liquid (F_{GW_W}). In the Fig. 1, the corresponding flux F_{GSW_diff} is the sum of F_{GS_diff} and F_{GW_diff} . F_{GW} is the sum of F_{GS_W} and F_{GW_W} . For the particle phase, in the above figure, the flux of F_{PO_W}) and dry deposition flux from particle to SPMs (F_{PO_D}). The flux of F_{PS_W} (flux from particle to soil) includes wet deposition flux from particle to soil (F_{PS_W}) and dry deposition flux from particle to soil (F_{PS_D}). In the Fig. 1, the corresponding flux F_{PD} is the sum of F_{PO_D} and F_{PS_D} . The flux F_{PW} is the sum of F_{PO_W} and F_{PS_W} .

Once the relationships between the six compartments were confirmed, the function between the total input flux and the total output flux can be established for each compartment. The relationship follows the general form:

$$E_{i} + \sum D_{ii}f_{i} = \sum D_{ik}f_{i} + D_{iR}f_{i}$$
 (S2)

where, E_i is the emission rate (mol/h) to compartment i; D_{ji} is the intermedia D values from compartment j to compartment i (mol/(Pa·h)); D_{ik} is the intermedia D values from compartment i to compartment k (mol/(Pa·h)); D_{iR} is the reaction rate D value in compartment i (mol/(Pa·h)); f_i and f_j are the fugacity of chemical in compartment i and compartment j (Pa).

- In the present study, both the gaseous and particulate emissions were considered
- 89 in the models. Therefore, the above equation for each compartment can be expressed as
- 90 follows in detail:
- 91 Air: Gas phase:

92
$$E_{G} + D_{LG}f_{L} + D_{SG}f_{S} + D_{PG}f_{P} = (D_{GL} + D_{GS} + D_{GP} + D_{GR})f_{G}$$
 (S3)

93 Air: Particle phase:

94
$$E_{\rm P} + D_{\rm GP} f_{\rm G} = (D_{\rm PG} + D_{\rm PS} + D_{\rm PO} + D_{\rm PR}) f_{\rm P}$$
 (S4)

95 Water: Dissolved phase:

96
$$D_{GL}f_G + D_{SL}f_S + D_{SedL}f_{Sed} + D_{OL}f_O = (D_{LG} + D_{LSed} + D_{LO} + D_{LR})f_L$$
 (S5)

97 Water: Solid phase:

98
$$D_{LO}f_L + D_{SO}f_S + D_{SedO}f_{Sed} + D_{PO}f_P = (D_{OL} + D_{OSed} + D_{OR})f_O$$
 (S6)

99 Soil phase:

$$D_{GS}f_G + D_{PS}f_P = (D_{SG} + D_{SL} + D_{SO} + D_{SR})f_S$$
 (S7)

101 Sediment phase:

$$D_{LSed}f_{S} + D_{OSed}f_{O} = (D_{SedL} + D_{SedO} + D_{SedR})f_{Sed}$$
 (S8)

- where D values for each intermedia process were given in **Table S1**.
- The fugacity capacity Z values of each compartment used for calculation of the D
- values can be obtained by the equations in **Table S2**. The parameters for PAHs and
- environment were given in **Tables S3**, **S4 S5 and S6**. In the present study, the unit of
- the system was assumed as a cuboid with the air surface area (A_A) of 1 m², water surface
- area $(A_{\rm W})$ of 0.7 m², and soil surface area $(A_{\rm S})$ of 0.3 m². The height and/or depth of air,
- water and soil are 1000, 10 and 0.15 m, respectively.
- The fugacity for each compartment can be obtained by analyzing the above
- equations. Then the parameters of each compartment and the parameters between

- different compartments can be calculated, such as fluxes, concentrations, mass fractions,
- and partitioning behavior (Qin et al., 2021; Li et al., 2021b; Li et al., 2021a).

115 Text S2. The calculation method of the output and input fluxes for the particle

phase and the gas phase compartments

- The 11 output and input fluxes for the particle phase and the gas phase can be
- calculated by the following equations:

$$\phi_0 E = E_{\rm P} \tag{S10}$$

$$F_{GP} = D_{GP} f_G \tag{S11}$$

$$F_{PG} = D_{GP} f_{P} \tag{S12}$$

$$F_{\text{Gdiff}} = (D_{\text{GDL}} + D_{\text{GDS}})f_{\text{G}}$$
 (S13)

$$F_{\rm GW} = (D_{\rm GWL} + D_{\rm GWS})f_{\rm G} \tag{S14}$$

$$F_{\text{diffG}} = D_{\text{LG}} f_{\text{L}} + D_{\text{SG}} f_{\text{S}} \tag{S15}$$

126
$$F_{PD} = (D_{PDO} + D_{PDS})f_{P} = D_{PD}f_{P}$$
 (S16)

127
$$F_{PW} = (D_{PWO} + D_{PWS})f_{P} = D_{PW}f_{P}$$
 (S17)

$$F_{\rm GR} = D_{\rm GR} f_{\rm G} \tag{S18}$$

$$F_{\rm PR} = D_{\rm PR} f_{\rm P} \tag{S19}$$

where the D values can be found in **Table S1**.

131 Text S3. The expression of the $\log K_P$ using fugacity method

The G/P partitioning coefficient (K_P) can be calculated as follows:

$$K_{\rm P} = (C_{\rm P}/C_{\rm G})/TSP \tag{S20}$$

- where C_P (ng/m³ air) and C_G (ng/m³) are the PAHs concentrations in particle phase and
- gas phase, respectively, and TSP is the concentrations of total suspended particles
- 136 ($\mu g/m^3$).
- 137 C_P can be transferred to C'_P (ng/m³ particle) based the following equation:

138
$$C_{\rm P} = C'_{\rm P} \times TSP/10^9 \rho_{\rm P}$$
 (S21)

- where C'_P (ng/m³ particle) is the PAHs concentrations in particle phase with different
- units, and ρ_P is the density of particles (kg/m³).
- 141 Then, the Eq. (S20) can be expressed in different form:

142
$$K_{\rm P} = (C'_{\rm P}/C_{\rm G})/10^9 \rho_{\rm P} \tag{S22}$$

- The ratio of C'_{P} to C_{G} can be calculated using the method from the multimedia
- 144 fugacity model:

$$C'_{P}/C_{G} = f_{P}Z_{P}/f_{G}Z_{G}$$
 (S23)

- where Z_P/Z_G equal to K_{PG} at equilibrium state, which can be calculated by the following
- 147 equation (Li et al., 2015):

$$K_{PG} = Z_P/Z_G = 10^9 \rho_P K_{P-HB}$$
 (S24)

- where K_{P-HB} is the G/P partitioning coefficient calculated from the H-B model (the
- equilibrium-state model) (Harner and Bidleman, 1998b).
- Summarizing the equations above, $\log K_P$ can be expressed as following equation:

$$\log K_{\rm P} = \log K_{\rm P-HB} + \log(f_{\rm P}/f_{\rm G}) \tag{S25}$$

Text S4. The introduction of the prediction models

The H-B model

154

155

161

169

170

171

172

Under assumptions that the dominate G/P distribution process was absorption and the system was in *equilibrium-state*, an equation (named as the H-B model in the present study) used to predict the value of K_P for SVOCs was derived in an early study (Harner and Bidleman 1998b)

$$\log K_{\rm P-HB} = \log K_{\rm OA} + \log f_{\rm OM} - 11.91 \tag{S26}$$

The L-M-Y model

Li et al. established a *steady-state* model (named as the *L-M-Y* model in the present study) for the investigation of the G/P partitioning behavior of PBDEs (Li et al. 2015).

The influences of dry and wet depositions of particles on the G/P partitioning were considered in the *L-M-Y* model. A non-equilibrium parameter caused by dry and wet depositions of particles, log α was introduced into the *L-M-Y* model:

$$\log K_{\text{P-LMY}} = \log K_{\text{P-HB}} + \log \alpha \tag{S27}$$

log
$$\alpha = -\log(1 + 4.18 \times 10^{-11} f_{\text{OM}} K_{\text{OA}})$$
 (S28)

Therefore, the *H-B* model is a special case of the *L-M-Y* model when the non-equilibrium term (log α) equal zero.

173 Text S5. The calculation method of the root mean square error

- To evaluate the performance of the new steady-state model, the root mean square
- error (*RMSE*) was calculated based on the following equation:

$$RMSE = \sqrt{\frac{1}{n} \sum (\log K_{P-P} - \log K_P)^2}$$
 (S29)

- where $\log K_{P-P}$ is the prediction data from the new steady-state model, and $\log K_P$ is the
- 178 monitored data.
- The smaller of the *RMSE* value indicated the better matching degree between the
- predicted data and the monitored data.
- 181

212 Table S6. The environmental parameters for the multimedia fugacity model

Parameters	Description	Value	Unit	Function
$k_{ m VG}$	Gas side MTC over water	3	m/h	
$k_{ m VW}$	Liquid side MTC	0.03	m/h	
$U_{ m R}$	Rainfall rate	9.70×10^{-5}	m/h	
Q	Scavenging ratio	2×10 ⁵	-	
\mathcal{V}_{P}	Volume fraction of aerosol particle	6.67×10^{-11}	-	$10^{-9}TSP/\rho_{\rm P}$
U_{D}	Dry deposition velocity	10.8	m/h	
$k_{ m EG}$	Gas side MTC over soil	1	m/h	
Y_3	Diffusion path length in soil	0.05	m	
$B_{ m MG}$	Molecular diffusivity in gas	0.04	m^2/h	
$B_{ m MW}$	Molecular diffusivity in liquid	4.00×10^{-6}	m^2/h	
$U_{ m WW}$	Liquid runoff rate from soil	3.90×10^{-5}	m/h	
$U_{ m EW}$	Solids runoff rate from soil	2.30×10 ⁻⁸	m/h	
$k_{ m SW}$	Liquid side MTC over sediment	0.01	m/h	
Y_4	Diffusion path length in sediment	0.005	m	
$U_{ m DO}$	SPMs deposition rate	4.60×10^{-8}	m/h	
$U_{ m RS}$	Sediment resuspension rate	1.10×10^{-8}	m/h	
$k_{ m PG}$	Gas-Particle Partitioning MTC	1.89×10^{1}	m/h	$CB_{ m PG}/l_{ m PG}$
$B_{ m PG}$	Molecular diffusivity in air	1.80×10^{-2}	m^2/h	
$l_{ m PG}$	Air boundary layer thickness	4.75×10^{-3}	m	
C	Accommodation coefficient	5	_	
$k_{ m WO}$	Solid-Dissolved Partitioning MTC	4.21×10^{-3}	m/h	$C B_{ m WO}/l_{ m WO}$
$B_{ m WO}$	Molecular diffusivity in water	4.00×10^{-6}	m^2/h	
$l_{ m WO}$	Water boundary layer thickness	4.75×10^{-3}	m	
C'	Accommodation coefficient	5	_	
$ ho_P/ ho_{ m O}/ ho_{ m Sed}$	Density of particles in air and water and sediment	1.50×10 ³	kg/m ³	
$d_{ m P}/d_{ m O}$	Diameter of particles in air and water	1.00×10 ⁻⁷	m	
TSP	Concentration of particles in air	1.00×10^{2}	ug/m^3	
SPM	Concentration of particles in water	10	g/m^3	

continued Table S6

Parameters	ters Description		Unit	Function
$f_{OC(O)}$	Fraction of organic carbon in SPMs	0.04	-	
$f_{ m OM(S)}$	Fraction of organic materials in soil	0.04	-	
$f_{ m OC(Sed)}$	Fraction of organic carbon in sediment	0.1	-	
$A_{ m P}$	Total area of particles in air	4	m^2	$6\times10^{-9}TSP\times V_{G}/(\rho_{P}d_{P})$
A_{O}	Total area of particles in Water	2800	m^2	$6\times10^{-3}SPM\times V_{\rm W}/(\rho_{\rm O}d_{\rm O})$

Note: The values of the parameters were cited from Mackay (2001) (Mackay, 2001).

S3. Figures

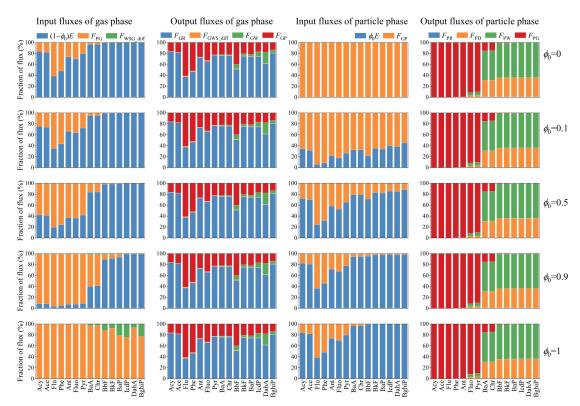

Fig. S1. Comparison of the fluxes for the input and output fluxes of the gas phase

and particle phase

Note: F_{GR} : degradation flux of gas phase PAHs; F_{PR} : degradation flux of particle phase PAHs; F_{GP} : migration flux from gas phase to particle phase; F_{PG} : migration flux from particle phase to gas phase; F_{GWS_diff} : diffusion fluxes from gas phase to water and soil phases; F_{GW} : wet deposition flux of gas phase PAHs; F_{WSG_diff} : diffusion fluxes from soil and water phases to gas phase; F_{PD} : dry deposition flux of particle phase PAHs; F_{PW} : wet deposition flux of particle phase PAHs; F_{PW} : wet deposition flux of particle phase PAHs; F_{PW} : emission flux of particle phase PAHs.

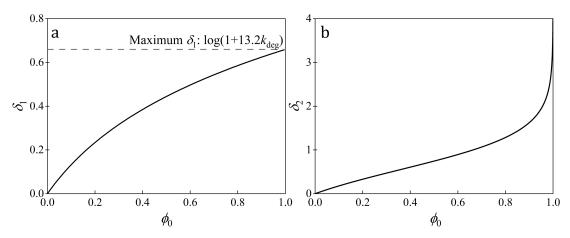

Fig. S2. The difference between the new steady-state model with the H-B model and the L-M-Y model

Note: δ_1 and δ_2 were calculated based on the value of $k_{\text{deg}} = 0.27 \text{ h}^{-1}$, δ_1 is the difference between the new steady-state model with the H-B model and the L-M-Y model when $\log K_{\text{OA}} < \log K_{\text{OA1}}$, and δ_2 is the difference between the new steady-state model with the L-M-Y model when $\log K_{\text{OA}} > \log K_{\text{OA2}}$.

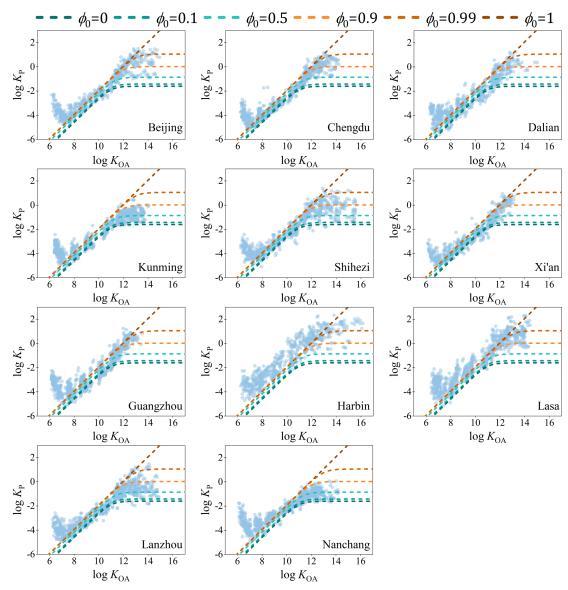

Fig. S3. The comparison between the monitored data of $\log K_{\rm P}$ of PAHs from 11 cities in China and the prediction lines of the new steady-state model with different values of ϕ_0 .

Note: the k_{deg} of 0.27 h⁻¹ and f_{OM} of 0.21 were used in the new steady-state model.

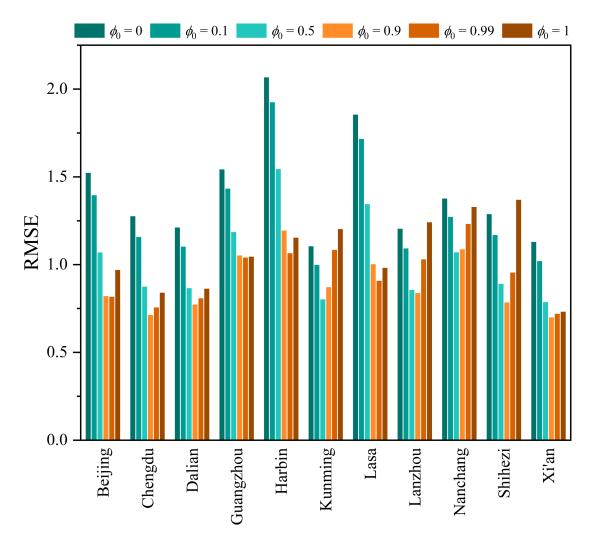

Fig. S4. The values of *RMSE* for the new steady-state model based on the monitored data from 11 cities in China

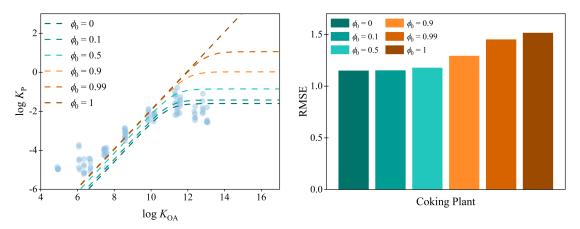

Fig. S5. The comparison between the monitored data of log K_P of PAHs from a coking plant and the prediction lines of the new steady-state model with different values of ϕ_0 (left panel) and the related values of *RMSE* of the new steady-state model (right panel)

Note: The k_{deg} of 0.27 h⁻¹ and f_{OM} of 0.21 were used in the new steady-state model; and the monitored data were cited from a coking plant(Liu et al., 2019).

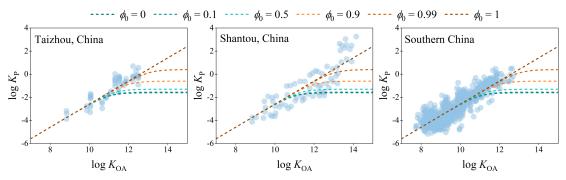

Fig. S6. The comparison between the monitored data of $\log K_{\rm P}$ of PBDEs from E-waste sites and the prediction lines of the new steady-state model with different values of ϕ_0

Note: The k_{deg} of 0.27 h⁻¹ and f_{OM} of 0.21 were used in the new steady-state model; and the monitored data were cited from the following references: Taizhou, China(Han et al., 2009); Shantou, China(Chen et al., 2011); and Southern China(Tian et al., 2011).

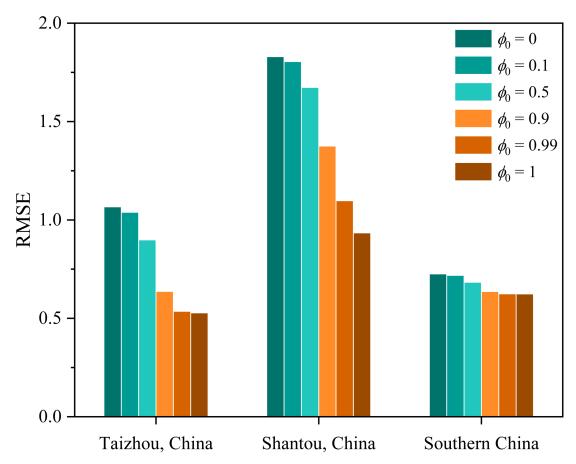

Fig. S7. The values of the *RMSE* of the new steady-state model based on the monitored data of PBDEs from e-waste sites
