

1 **Responses to Referee #1's comments**

2 We are grateful to the reviewers for their valuable and helpful comments on our manuscript
3 "Reaction of SO₃ with H₂SO₄ and Its Implication for Aerosol Particle Formation in the Gas Phase
4 and at the Air-Water Interface" (MS No.: **egusphere-2023-2009**). We have revised the manuscript
5 carefully according to reviewers' comments. The point-to-point responses to the Referee #1's
6 comments are summarized below:

7

8 **Referee Comments:**

9 Rui Wang and co-authors have used computational methods to study the formation and clustering
10 of H₂S₂O₇-known (depending on the source) as either disulfuric acid, pyrosulfuric acid, or oleum.
11 The technical methods used in the study are broadly appropriate, and the context (atmospheric new-
12 particle formation involving different sulfur compounds) is certainly relevant and broadly
13 interesting. The study is thus without doubt publishable. However, I have some critical notes about
14 the interpretation of the results, and their atmospheric implications (which I believe to be overstated,
15 at least in the context of Earth's lower atmosphere).

16 **Response:** We would like to thank the reviewer for the positive and valuable comments, and we
17 have revised our manuscript accordingly.

18 **Major issues**

19 **Comment 1.**

20 As shown by Torrent-Sucarrat (JACS 2012; cited in the present study), the SO₃ + H₂SO₄ reaction in
21 the presence of water can also lead directly to H₂SO₄ + H₂SO₄ (instead of H₂S₂O₇). Given that
22 H₂SO₄ is pretty much always hydrated, water is - as the authors themselves argue here - essentially
23 always present in the reaction system, at least in the lower troposphere. Thus, an explicit
24 consideration of the competition between the two channels would be warranted - however this seems
25 to be missing in the study. The authors should try to estimate what percentage of SO₃ + H₂SO₄
26 collisions, in different hydration environments, we can expect to yield (at least transiently, see below)
27 H₂S₂O₇, as compared to H₂SO₄ + H₂SO₄? (Note that this question should be asked on top of the
28 question that they DO address, i.e. "what fraction of SO₃ will collide with H₂SO₄ as opposed to H₂O,
29 or H₂O*X, where X is any other catalyst for the SO₃ hydration reaction. As per the authors own

1 calculation in their Table S6, already this percentage is very small-despite their neglect of many
2 other known candidates for X.)

3 **Response:** Thanks for your valuable comments. According to the reviewer's suggestion, the
4 schematic potential energy surface of the H₂SO₄ formation from the SO₃ + H₂SO₄ reaction with
5 H₂O has been added in Fig. 1, while the corresponding effective rate constants have been listed in
6 Table 1. Then, the competition between H₂SO₄ and H₂S₂O₇ formations from the SO₃ + H₂SO₄
7 reaction with H₂O have been discussed. The corresponding major revision has been made as follows.

8 (a) The SO₃ + H₂SO₄ reaction with H₂O can produce two distinct products, labeled (i) H₂S₂O₇
9 (DSA, Channel DSA_WM) and (ii) H₂SO₄ (SA, Channel SA_SA). A single water molecule in (i)
10 acts as a catalyst, while it plays as a reactant in (ii). So, based on the H₂S₂O₇ formation from the
11 SO₃ + H₂SO₄ reaction with H₂O, the schematic potential energy surface for the H₂SO₄ formation
12 from the SO₃ + H₂SO₄ reaction with H₂O is also involved in Fig. 1. In Lines 18-21 Page 8 of the
13 revised manuscript, the corresponding discussion has been reorganized as “The SO₃ + H₂SO₄
14 reaction with H₂O produced two distinct products, labeled (i) H₂S₂O₇ (DSA, Channel DSA_WM)
15 and (ii) H₂SO₄ (SA, Channel SA_SA). A single water molecule in (i) acted as a catalyst, while it
16 played as a reactant in (ii). The schematic potential energy surface for the SO₃ + H₂SO₄ reaction
17 with H₂O was shown in Fig. 1.”

18 (b) Similar with the H₂S₂O₇ formation from the SO₃ + H₂SO₄ reaction with H₂O (Fig. 1 (b),
19 Channel DSA_WM), the H₂SO₄ formation from the SO₃ + H₂SO₄ reaction with H₂O (Fig. 1 (c),
20 Channel SA_SA) can be considered as a sequential bimolecular process. In other words, Channel
21 SA_SA occurs via the collision between SO₃ (or H₂SO₄) and H₂O to form dimer (SO₃···H₂O and
22 H₂SO₄···H₂O) first, and then the dimer encounters with the third reactant H₂SO₄ or SO₃. However,
23 the SO₃···H₂O + H₂SO₄ reaction in Channel SA_SA can be neglected as its effective rate constant
24 is smaller by 1.02-3.05 times than the corresponding value in the H₂SO₄···H₂O + SO₃ reaction.
25 Therefore, we only consider the H₂SO₄···H₂O + SO₃ bimolecular reaction in Channel SA_SA. In
26 Lines 21-29 Page 8 to lines 1-17 Page 9 of the revised manuscript, two sequential bimolecular
27 processes, H₂SO₄···H₂O + SO₃ and SO₃···H₂O + H₂SO₄, have been considered, which has been
28 reorganized as “As the probability of simultaneous collision (Pérez-Ríos et al., 2014; Elm et al.,
29 2013) of three molecules of SO₃, SA and H₂O is quite low under realistic conditions, both Channel
30 DSA_WM and Channel SA_SA can be considered as a sequential bimolecular process. In other

1 words, both Channel DSA_WM and Channel SA_SA occur via the collision between SO₃ (or H₂SO₄)
2 and H₂O to form dimer (SO₃···H₂O and H₂SO₄···H₂O) first, and then the dimer encounters with the
3 third reactant H₂SO₄ or SO₃. The computed Gibbs free energies of dimer complexes SO₃···H₂O and
4 H₂SO₄···H₂O were respectively 0.8 kcal·mol⁻¹ and -1.9 kcal·mol⁻¹, which were respectively
5 consistent with the previous values (the range from -0.2 to 0.62 kcal·mol⁻¹ for SO₃···H₂O complex
6 (Bandyopadhyay et al., 2017; Long et al., 2012) and the range from -1.82 to -2.63 kcal·mol⁻¹ for
7 H₂SO₄···H₂O complex (Long et al., 2013b; Tan et al., 2018)). The Gibbs free energy of H₂SO₄···H₂O
8 was lower by 2.7 kcal·mol⁻¹ than that of SO₃···H₂O, thus leading to that the equilibrium constant of
9 the former complex is larger by 1-2 orders of magnitude than that of the latter one in Table S2.
10 Additionally, the larger equilibrium constant of H₂SO₄···H₂O complex leads to its higher
11 concentration in the atmosphere. For example, when the concentrations of SO₃ (Yao et al., 2020),
12 H₂SO₄ (Liu et al., 2015) and H₂O (Anglada et al., 2013) were 10⁶, 10⁸ and 10¹⁷ molecules·cm⁻³,
13 respectively, the concentrations of SO₃···H₂O and H₂SO₄···H₂O were 2.41 × 10³-2.01 × 10⁴ and
14 5.01 × 10⁵-3.01 × 10⁸ molecules·cm⁻³ within the temperature range of 280-320 K (see Table S3),
15 respectively. So, we predict that Channel DSA_WM and Channel SA_SA mainly take place via the
16 collision of H₂SO₄···H₂O with SO₃. In order to check this prediction, the effective rate constants for
17 two bimolecular reactions of H₂SO₄···H₂O + SO₃ and SO₃···H₂O + H₂SO₄ were calculated, and the
18 details were shown in *SI Appendix*, Part 3 and Table 1. As seen in Table 1, the SO₃···H₂O + H₂SO₄
19 reaction in both Channel DSA_WM and Channel SA_SA can be neglected as their effective rate
20 constants are smaller by 16.7-48.5 and 1.02-3.05 times than the corresponding values in the
21 H₂SO₄···H₂O + SO₃ reaction within the temperature range of 280-320 K, respectively. Therefore,
22 we only consider the H₂SO₄···H₂O + SO₃ bimolecular reaction in both Channel DSA_WM and
23 Channel SA_SA.”

24 (c) As for the H₂SO₄ formation from the SO₃ + H₂SO₄ reaction with H₂O, the discussion of
25 the stepwise H₂SO₄···H₂O + SO₃ reaction has been added in Lines 8-21 Page 10 of the revised
26 manuscript, which has been reorganized as “Regarding Channel SA_SA, the stepwise reaction
27 occurred firstly via the ring enlargement from six-membered ring complex IM_{SA_SA}' to a cage-like
28 hydrogen bonding network IM_{SA_SA}, and then took place by going through a transition state, TS_{SA_SA},
29 to from the product complex (H₂SO₄)₂. TS_{DSA_WM} was in the middle of a double hydrogen transfer,
30 where H₂SO₄ acted as a bridge of hydrogen atom from the H₂O to SO₃ along with O1 atom of H₂O

1 addition to the S atom of SO₃. It is worth noting that the energy barriers of two elementary reactions
 2 involved in the stepwise route of Channel SA_SA were only 1.8 and 0.6 kcal·mol⁻¹, respectively,
 3 showing that the stepwise route of Channel SA_SA is feasible to take place from energetic point of
 4 view.

5 (d) The discussion of the competition between the SO₃ + H₂SO₄ reaction with H₂O and the
 6 hydrolysis of SO₃ with H₂SO₄ have been discussed in Lines 8-14 Page 9 of the revised manuscript,
 7 which has been reorganized as “To check whether Channel DSA_WM is more favorable than
 8 Channel SA_SA or not, their rate ratio listed in Eq. 4 has been calculated in Table 1. The calculated
 9 rate ratio $\frac{v_{\text{DSA_WM}_s}}{v_{\text{SA_SA}_s}}$ shows that Channel DSA_WM is more important than Channel SA_SA
 10 because the rate ratio $\frac{v_{\text{DSA_WM}_s}}{v_{\text{SA_SA}_s}}$ is 1.53-3.04 within the temperature range of 280-320 K. So,
 11 we predicted that the SO₃ + H₂SO₄ reaction with H₂O producing H₂S₂O₇ is more favorable than that
 12 forming H₂SO₄.

$$13 \quad \frac{v_{\text{DSA_WM}}}{v_{\text{SA_SA}}} = \frac{v_{\text{DSA_WM}_s} + v_{\text{DSA_WM}_o}}{v_{\text{SA_SA}_s} + v_{\text{SA_SA}_o}} = \frac{k_{\text{DSA_WM}_s} \times K_{\text{eq}(\text{H}_2\text{SO}_4 \cdots \text{H}_2\text{O})} + k_{\text{DSA_WM}_o} \times K_{\text{eq}(\text{SO}_3 \cdots \text{H}_2\text{O})}}{k_{\text{SA_SA}_s} \times K_{\text{eq}(\text{H}_2\text{SO}_4 \cdots \text{H}_2\text{O})} + k_{\text{SA_SA}_o} \times K_{\text{eq}(\text{SO}_3 \cdots \text{H}_2\text{O})}} \quad (4)''$$

14 Overall, in the SO₃ + H₂SO₄ reaction with H₂O, a single water molecule both acting as a
 15 catalyst and a reactant has been investigated. Meanwhile, these two kinds of reactions mainly take
 16 place via the collision of H₂SO₄···H₂O with SO₃. Moreover, the SO₃ + H₂SO₄ reaction with H₂O
 17 producing H₂S₂O₇ is more favorable than that forming H₂SO₄ as the rate ratio $\frac{v_{\text{DSA_WM}}}{v_{\text{SA_SA}}}$ is
 18 1.53-3.04 within the temperature range of 280-320 K.

$T(\text{K})$	280 K	290 K	298 K	300 K	310 K	320 K
k_{DSA}	5.52×10^{-12}	4.60×10^{-12}	3.95×10^{-12}	3.80×10^{-12}	3.13×10^{-12}	2.57×10^{-12}
$k'_{\text{DSA_WM}_o}$	2.12×10^{-13}	2.68×10^{-13}	2.88×10^{-13}	2.89×10^{-13}	2.89×10^{-13}	2.75×10^{-13}
$k'_{\text{DSA_WM}_s}$	1.03×10^{-11}	8.55×10^{-12}	7.42×10^{-12}	7.11×10^{-12}	5.79×10^{-12}	4.60×10^{-12}
$k'_{\text{SA_SA}_o}$	1.29×10^{-21}	8.69×10^{-22}	6.00×10^{-22}	5.37×10^{-22}	3.47×10^{-22}	2.28×10^{-22}

$k'_{SA_SA_s}$	3.93×10^{-21}	1.82×10^{-21}	1.01×10^{-21}	8.62×10^{-12}	4.42×10^{-12}	2.34×10^{-12}
$\frac{\nu_{DSA_WM}}{\nu_{SA_SA}}$	3.04	2.61	2.30	2.22	1.85	1.53

1 k_{DSA} is the rate constant for the $SO_3 + H_2SO_4$ reaction; $k'_{DSA_WM_o}$ and $k'_{DSA_WM_s}$ are respectively the effective rate
2 constants for H_2O -assisted $SO_3 + H_2SO_4$ reaction occurring through one-step and stepwise routes. $k'_{SA_SA_o}$ and
3 $k'_{SA_SA_s}$ are respectively the effective rate constants for the hydrolysis reaction of SO_3 with H_2SO_4 occurring through
4 one-step and stepwise routes. ν_{DSA_WM}/ν_{SA_SA} is the rate ratio between Channel DSA_WM and Channel SA_SA.

5

6 **Comment 2.**

7 While interesting, I'm not sure the BOMD simulations are saying much about the relevance of
8 $H_2S_2O_7$ for actual new-particle formation: $H_2S_2O_7$ formed in water droplets will presumably stay
9 there, and never evaporate to participate in NPF. (Overall, "air-water interfaces" have little to do
10 with actual NPF, as the interfaces are by definition found in particles that *have already formed*:
11 many of the claims of "NPF-relevance" made in the study are thus by definition incorrect). While
12 there may be some relevance of the studied process to particle growth, even H_2SO_4 has an essentially
13 zero evaporation rate from any particles larger than a few nanometers - so it may make little
14 difference to the growth of larger aerosol whether the sulfur is taken up as H_2SO_4 or $H_2S_2O_7$ (also
15 see issue 4 for a further caveat).

16 **Response:** Thanks for your valuable comments. We agree with the suggestion of the reviewer that
17 the reaction of $H_2S_2O_7$ or H_2SO_4 formations at air-water interface is not directly related to new
18 particle formation. However, the reaction of $H_2S_2O_7$ or H_2SO_4 formations at air-water interface is
19 necessary to investigate by using BOMD simulations. This is because that

20 (a) Many investigations (*J. Am. Chem. Soc.*, 2016, 138, 1816-1819; *Proc. Natl. Acad. Sci.*
21 *U.S.A*, 2017, 114, 12401-12406.; *J. Am. Chem. Soc.*, 2018, 140, 6456-6466.; *J. Am. Chem. Soc.*,
22 2018, 140, 14, 4913-4921.; *Chem. Sci.*, 2019, 10, 743-751.; *Chem. Sci.*, 2017,8, 5385-5391.)
23 suggest that interfacial environment not only triggers the arrangement and aggregation of
24 hydrophilic groups, but also provides a good medium for many atmospheric reactions. Notably, due
25 to the induction of proton transfer pathways by interfacial water molecules, many atmospheric
26 reactions that occur on the surface of aerosols and droplets are faster, and sometimes are different
27 from the corresponding processes in the gas phase. Based on this, the differences in the reactivity
28 of SO_3 with H_2SO_4 in the gas phase and at the air-water interface were evaluated by using BOMD
29 simulations.

1 (b) The BOMD simulation results at the air-water interface suggest that three different types
2 of interfacial reaction mechanisms (i) H₂O-induced the formation of S₂O₇²⁻···H₃O⁺ ion pair; (ii)
3 HSO₄⁻ mediated the formation of HSO₄⁻···H₃O⁺ ion pair and (iii) the deprotonation of H₂S₂O₇ were
4 observed. These interfacial reactions occurred through stepwise mechanism to form the ion pair of
5 S₂O₇²⁻···H₃O⁺ and HSO₄⁻···H₃O⁺, and proceed on the picosecond time scale. These interfacial
6 mechanisms are in contrast to the gas phase reaction mechanisms in which loop-structure
7 mechanism were involved in SO₃ + H₂SO₄ reaction without and with H₂O. Thus, the SO₃ + H₂SO₄
8 reaction behavior at the air-water interface is different from that of the gas phase, and some new and
9 different mechanisms have been found.

10 (c) Although the formation routes of the S₂O₇²⁻···H₃O⁺ and HSO₄⁻···H₃O⁺ ion pair at air-water
11 interface is not directly related to new particle formation, the S₂O₇²⁻ ion at the air-water interface
12 has stronger nucleation potential as the following reasons. One reason is that the interactions of
13 S₂O₇²⁻···H₂SO₄, S₂O₇²⁻···HNO₃, S₂O₇²⁻···(COOH)₂, H₃O⁺···NH₃, H₃O⁺···H₂SO₄, SA⁻···H₂SO₄, SA⁻
14 ···(COOH)₂, and SA⁻···HNO₃ listed in Table 2 are stronger than those of H₂SO₄···NH₃ (major
15 precursor of atmospheric aerosols). These results reveal that interfacial S₂O₇²⁻, SA⁻ and H₃O⁺ can
16 attract candidate species from the gas phase to the water surface. The other reason is that as
17 compared with (SA)₁(A)₁(X)₁ (X = HOOCCH₂COOH, HOCCOOSO₃H, CH₃OSO₃H,
18 HOOCCH₂CH(NH₂)COOH and HOCH₂COOH) clusters (Zhong et al., 2019; Zhang et al., 2018;
19 Rong et al., 2020; Gao et al., 2023; Liu et al., 2021a; Zhang et al., 2017), the number of hydrogen
20 bonds in (SA)₁(A)₁(S₂O₇²⁻)₁ cluster presented in Fig. S8 increased and the ring of the complex was
21 enlarged. Meanwhile, comparing to (SA)₁(A)₁(X)₁ (X = HOOCCH₂COOH, HOCCOOSO₃H,
22 CH₃OSO₃H, HOOCCH₂CH(NH₂)COOH and HOCH₂COOH) clusters (Table 2), the Gibbs
23 formation free energy ΔG of (SA)₁(A)₁(S₂O₇²⁻)₁ cluster is lower, showing S₂O₇²⁻ ion at the air-water
24 interface has stronger nucleation ability than X in the gas phase. Based on this, the sentence of “**and**
25 **thus in turn accelerates the growth of particle.**” has been deleted in Line 14 Page 14 of the revised
26 manuscript. Similarly, the sentence of “**enhancing potential of S₂O₇²⁻ on SA-A cluster**” has been
27 changed as “**the nucleation potential of S₂O₇²⁻ on SA-A cluster**” in Line 15 Page 16 of the revised
28 manuscript. Moreover, the sentence of “**the Gibbs formation free energy ΔG of (SA)₁(A)₁(S₂O₇²⁻)₁**
29 **cluster is lower. Therefore, we predict that S₂O₇²⁻ at the air-water interface has important implication**
30 **to the aerosol NPF in highly industrial polluted regions with high concentrations of SO₃.**” has been

1 changed as “the Gibbs formation free energy ΔG of $(SA)_1(A)_1(S_2O_7^{2-})_1$ cluster is lower, showing
2 $S_2O_7^{2-}$ ion at the air-water interface has stronger nucleation ability than X in the gas phase. Therefore,
3 we predict that $S_2O_7^{2-}$ at the air-water interface has stronger nucleation potential.” in Lines 23-26
4 Page 16 of the revised manuscript.

5 Overall, the BOMD simulations of three different types of interfacial reaction mechanisms (*i*)
6 H_2O -induced the formation of $S_2O_7^{2-}\cdots H_3O^+$ ion pair; (*ii*) HSO_4^- mediated the formation of HSO_4^-
7 $\cdots H_3O^+$ ion pair and (*iii*) the deprotonation of $H_2S_2O_7$ were studied. These interfacial reactions
8 occurred through stepwise mechanism and were in contrast to the gas phase reaction mechanisms
9 in which loop-structure mechanism were involved in $SO_3 + H_2SO_4$ reaction without and with H_2O .
10 Then, the nucleation potential of $S_2O_7^{2-}$ at the air-water interface has been investigated by
11 considering the adsorption capacity of the $S_2O_7^{2-}$, H_3O^+ and SA^- to gaseous precursors in the
12 atmosphere as well as the geometrical structure and the formation free energies of the
13 $(SA)_1(A)_1(S_2O_7^{2-})_1$ clusters.

14 15 **Comment 3.**

16 The authors spend much time discussing the results they obtain for the “enhancement factor” R
17 (equation 5). As cautioned in Elm et al. (<https://www.sciencedirect.com/science/article/abs/pii/S0021850220301099>), the excessive use of such abstract “enhancement factors” is
18 questionable and risky. In this particular case, I don’t believe the results are actually technically
19 badly wrong - for example including the effect of H_2SO_4 depletion (caused by a fraction of the SO_3
20 forming DSA rather than H_2SO_4) would probably not change the qualitative results, as the clustering
21 ability of DSA is much greater than that of H_2SO_4 . (For completeness sake, I would nevertheless
22 recommend this is done). However, many of the presented “results” are in reality rather trivial
23 consequence of how the simulation is set up, and the parameters defined. For example, the R values
24 are quite obviously “greater than or equal to 1”, as the J values with added DSA cannot (in the way
25 the authors run ACDC) be lower than the J values without the added DSA. Similarly, the various
26 correlations between R and different parameters are not particularly informative or novel. I
27 recommend the authors first of all account for all relevant effects (including sulfur depletion - ie run
28 the code with a constant SO_3 source rather than constant $[H_2SO_4]$), and also condense the discussion
29 on “enhancement factors”.
30

1 **Response:** Thanks for your valuable comments. The reason for using a constant SO₃ source is not
2 reasonable has been explained firstly. Meanwhile, the corresponding discussion on “enhancement
3 factors” have been condensed and the analysis of the absolute formation rate with temperature and
4 concentration changes after the addition of H₂S₂O₇ has been added. The corresponding major
5 revision has been made as follows.

6 (a) It is not reasonable to use a constant SO₃ source since there are many pathways for the
7 removal of SO₃ removal processes. the hydrolysis of SO₃ to product H₂SO₄ is the most major loss
8 route of SO₃ in the atmosphere. As a complement to the loss of SO₃, ammonolysis reaction of SO₃
9 in polluted areas of NH₃ can form H₂NSO₃H, which can be competitive with the formation of H₂SO₄
10 from the hydrolysis reaction of SO₃. Besides, the reactions of SO₃ with CH₃OH, HNO₃, and organic
11 acids (e.g., formic acid, acetic acid and acrylic acid). These reactions consume some SO₃ in the
12 atmosphere and inhibit the hydrolysis of SO₃ (H₂SO₄ formation) to some extent. Thus, it is not
13 suitable to use a constant source of SO₃.

14 The concentration of H₂S₂O₇ has been re-evaluated within the altitude range of 0-30 km. Then,
15 the analysis of the absolute formation rate with temperature and concentration changes after the
16 addition of H₂S₂O₇ has been added in Lines 28-30 Page 14 to Lines 1-13 Page 15 of the revised
17 manuscript, which has been organized as “The potential enhancement influence of DSA to the SA-
18 A-based particle formation was shown in Fig. 6. The formation rate (J , cm⁻³·s⁻¹) of SA-A-DSA-
19 based system illustrated in Fig. 6 was negatively dependent on temperature, demonstrating that the
20 low temperature is a key factor to accelerate cluster formation. It is noted that, at low temperatures
21 of 218.15 K (Fig. S12) and 238.15 K (Fig. S13), the actual ΔG of clusters has been calculated to
22 ensure meaningful cluster dynamics of the 3 × 3 systems, where the actual ΔG surface represented
23 that the simulated set of clusters always included the critical cluster. In addition to temperature, the
24 J of SA-A-DSA-based system shown in Fig. 6 rise with the increase of [DSA]. More notably, the
25 participation of DSA can promote J to a higher level, indicating its enhancement on SA-A
26 nucleation. Besides, there was significantly positive dependence of the J of SA-A-DSA-based
27 system on both [SA] and [A] in Fig. 7 (238.15 K) and Fig. S15-Fig. S18 (218.15, 258.15, 278.15
28 and 298.15 K). This was because the higher concentration of nucleation precursors could lead to
29 higher J . Besides, Fig. S19 showed the nucleation rate when the sum ([SA] + [DSA]) was kept
30 constant. $J_{\text{DSA/SA}}$ at substituted condition was higher than that at unsubstituted condition. These

1 results indicated that DSA may can greatly enhance the SA-A particle nucleation in heavy sulfur
2 oxide polluted atmospheric boundary layer, especially at an average flight altitude of 10 km with
3 high [DSA].”

4

5 **Comment 4**

6 The most problematic part of the overall claim for atmospheric relevance is the neglect of H₂S₂O₇
7 decomposition by hydration (i.e. the H₂S₂O₇ + H₂O ⇒ H₂SO₄ + H₂SO₄ reaction), which is very
8 well known (e.g. from industrial sulfur chemistry) to be rapid and spontaneous. (Indeed, H₂S₂O₇ is
9 one of the strongest dehydrating agents in the known universe - its hydration reaction is so strong
10 and favourable that it can even extract water molecules from sugar.) The BOMD simulations
11 indicate that H₂S₂O₇ is stable for 10 picoseconds - but this is nowhere near enough time for a H₂S₂O₇
12 to, for example, collide with a H₂SO₄ (timescale: seconds) in the gas phase (and thus participate in
13 NPF). Recently, another group showed that preliminary results on the role of sulfamic acid in new-
14 particle formation are invalidated by rapid hydrolysis ([https://pubs.acs.org/doi/full/10.1021/acs.jpca.](https://pubs.acs.org/doi/full/10.1021/acs.jpca.3c04982)
15 [3c04982](https://pubs.acs.org/doi/full/10.1021/acs.jpca.3c04982)) - I anticipate something very similar may end up being the case for di/pyrosulfuric acid
16 in the Earth’s lower atmosphere. Having said that, the presented results may very well have
17 relevance for stratospheric chemistry, as well as for cloud chemistry on Venus (where there is much
18 less water, and much more H₂SO₄). I recommend the atmospheric implications and relevance
19 discussion be reformulated to target the appropriate atmospheres /or regions of them. Or at the very
20 least, the possible (even likely) rapid hydrolysis of H₂S₂O₇ should be mentioned as a major caveat
21 of the results (and as a strongly recommended subject for follow-up studies!)

22 **Response:** Thanks for your valuable comments. According to the reviewer’s suggestion, the
23 importance of the SO₃ + H₂SO₄ reaction has been investigated in the atmospheres of Earth and Venus.
24 Meanwhile, the concentration of H₂S₂O₇ has been re-evaluated where the end and outside the
25 aircraft engine and flight was considered. The corresponding revision has been made as follows.

26 (a) To understand the competition between the SO₃ + H₂SO₄ reaction and H₂O-assisted
27 hydrolysis of SO₃ in the Earth’s atmosphere, the rate ratio (v_{DSA}/v_{SA}) between the SO₃ + H₂SO₄
28 reaction and H₂O-assisted hydrolysis of SO₃ has been calculated and was expressed in Eq. (5).

29
$$\frac{v_{\text{DSA}}}{v_{\text{SA}}} = \frac{k_{\text{DSA}} \times [\text{SO}_3] \times [\text{H}_2\text{SO}_4] + k_{\text{DSA_WM_s}} \times K_{\text{eq1}} \times [\text{SO}_3] \times [\text{H}_2\text{SO}_4] \times [\text{H}_2\text{O}]}{k_{\text{SA_WM}} \times K_{\text{eq2}} \times [\text{SO}_3] \times [\text{H}_2\text{O}] \times [\text{H}_2\text{O}]} \quad (5)$$

1 In Eq. (5), K_{eq1} and K_{eq2} were the equilibrium constant for the formation of $H_2SO_4 \cdots H_2O$ and
2 $SO_3 \cdots H_2O$ complexes shown in Table S2, respectively; k_{DSA} , $k_{DSA_WM_s}$ and k_{SA_WM} were
3 respectively denoted the bimolecular rate coefficient for the $H_2SO_4 + SO_3$, $H_2SO_4 \cdots H_2O + SO_3$ and
4 $SO_3 \cdots H_2O + H_2O$ reactions; $[H_2O]$ and $[H_2SO_4]$ were respectively represented the concentration of
5 H_2O and H_2SO_4 taken from references (*J. Phys. Chem. A*, 2013, 117, 10381-10396.; *Environ. Sci.*
6 *Technol.*, 2015, 49, 13112-13120.). The corresponding rate ratio have been listed in Table S7 (0 km
7 altitude) and S8 (5-30 km altitude). As seen in Table S7, at 0 km altitude, the hydrolysis reaction of
8 SO_3 with $(H_2O)_2$ is more favorable than the $SO_3 + H_2SO_4$ reaction as the $[H_2O]$ (10^{16} - 10^{18}
9 $molecules \cdot cm^3$) is much larger than that of $[H_2SO_4]$ (10^4 - 10^8 $molecules \cdot cm^3$). Although the
10 concentration of water molecules decreases with the increase of altitude in Table S8, the
11 concentration of $[H_2O]$ is still much greater than that of $[H_2SO_4]$, resulting in the $SO_3 + H_2SO_4$
12 reaction cannot compete with H_2O -assisted hydrolysis of SO_3 within the altitude range of 5-30 km.
13 Moreover, the $SO_3 + H_2SO_4$ reaction is not also the major sink route of SO_3 , even considering of
14 high H_2SO_4 concentration at the end and outside the aircraft engine and flight. Based on this, the
15 sentence of “The value of v_{DSA}/v_{SA} was listed in Table S7 (0 km altitude) and S8 (5-30 km altitude).
16 As seen in Table S7, at 0 km altitude, the hydrolysis reaction of SO_3 with $(H_2O)_2$ is more favorable
17 than the $SO_3 + H_2SO_4$ reaction as the $[H_2O]$ (10^{16} - 10^{18} $molecules \cdot cm^3$) is much larger than that of
18 $[H_2SO_4]$ (10^4 - 10^8 $molecules \cdot cm^3$). Although the concentration of water molecules decreases with
19 the increase of altitude in Table S8, the concentration of $[H_2O]$ is still much greater than that of
20 $[H_2SO_4]$, resulting in the $SO_3 + H_2SO_4$ reaction cannot compete with H_2O -assisted hydrolysis of
21 SO_3 within the altitude range of 5-30 km. Even considering of high H_2SO_4 concentration at the end
22 and outside the aircraft engine and flight at 10 km, the $SO_3 + H_2SO_4$ reaction is not also the major
23 sink route of SO_3 .” has been added in Lines 24-29 Page 13 to Lines 1-4 Page 14 of the revised
24 manuscript.

25 (b) It has been proposed that the concentration of sulfuric acid is even greater than that of water
26 vapor in the atmosphere of Venus (*Science*, 1990, 249, 1273.; *Planet. Space Sci.*, 2006, 54, 1352.;
27 *Icarus*, 1994, 109, 58.; *Nat. Geosci.*, 2010, 3, 834.), which may lead to that the $SO_3 + H_2SO_4$ reaction
28 is probably favorable than the H_2O -assisted hydrolysis of SO_3 in the Venus’ atmosphere. To check
29 whether the $SO_3 + H_2SO_4$ reaction is more favorable than H_2O -assisted hydrolysis of SO_3 or not in
30 the Venus’ atmosphere, the rate ratio of v_{DSA}/v_{SA} listed in Eq. 4 has been calculated in Table 2. It

1 can be seen from Table 2 that the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ is 3.24×10^8 - 5.23×10^{10} in the 40-70 km
2 altitude range of Venus, which indicates that the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction is significantly more
3 favorable than the hydrolysis reaction of $\text{SO}_3 + (\text{H}_2\text{O})_2$ within the altitudes range of 40-70 km in the
4 Venus' atmosphere. Based on this, the sentence of “Notably, as the concentration of sulfuric acid is
5 even greater than that of water vapor in the atmosphere of Venus, the $\text{SO}_3 + \text{SA}$ reaction is probably
6 favorable than the H_2O -assisted hydrolysis of SO_3 in the Venus' atmosphere. To check whether the
7 $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction is more favorable than H_2O -assisted hydrolysis of SO_3 or not in the Venus'
8 atmosphere, the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ listed in Eq. 4 has been calculated in Table 2. It can be seen
9 from Table 2 that the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ is 3.24×10^8 - 5.23×10^{10} in the 40-70 km altitude range
10 of Venus, which indicates that the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction is significantly more favorable than the
11 hydrolysis reaction of $\text{SO}_3 + (\text{H}_2\text{O})_2$ within the altitudes range of 40-70 km in the Venus' atmosphere.”
12 has been added in Lines 4-11 Page 14 of the revised manuscript.

13 (c) Considering the concentration of sulfuric acid at the end and outside the aircraft engine and
14 flight (up to 600 pptv), the concentration of $\text{H}_2\text{S}_2\text{O}_7$ has been re-evaluated within the altitude range
15 of 0-30 km. Specifically, the steady-state concentration of DSA was calculated using the calculated
16 equilibrium constant listed in Eq. S5.

$$17 \quad K_{\text{eq}3} = \frac{[\text{DSA}]}{[\text{SO}_3][\text{SA}]} \quad (\text{S5})$$

18 where $K_{\text{eq}3}$ is the equilibrium constant of DSA with respect to SO_3 and H_2SO_4 within the altitude
19 range of 0-30 km shown in Table S9; $[\text{SO}_3]$, $[\text{SA}]$ and $[\text{DSA}]$ are the concentrations of SO_3 , H_2SO_4 ,
20 and $\text{H}_2\text{S}_2\text{O}_7$, respectively. Although the concentration of sulfur trioxide remains unknown at
21 different altitudes, experimental observations have shown that the concentration of sulfur trioxide
22 can reach 10^6 molecules cm^{-3} in the troposphere. Moreover, water vapor concentrations significantly
23 decrease with increasing of altitude. Consequently, the concentration of sulfur trioxide should be
24 higher in the stratosphere than in the troposphere, and its concentration would increase as a result
25 of geoengineered injection of SO_2 or SO_3 . Besides, it is worth noting that H_2SO_4 can form at the
26 end and outside the engine, and flight measurements in the exhaust plume have measured sulfuric
27 acid abundances up to a value of 600 pptv. When an average flight altitude of 10 km is considered,
28 this corresponds to a concentration of 5.1×10^9 molecules $\cdot \text{cm}^{-3}$. Therefore, we have calculated the
29 concentrations of DSA according to concentrations of sulfur trioxide in the range from 10^7 to 10^{14}

1 molecules cm^{-3} and the concentrations of H_2SO_4 in the range of 10^4 - 10^9 molecules cm^{-3} as shown
2 in Fig. S9.

3 The maximum concentration of DSA displayed in Fig. S9 can be up to 10^8 molecules $\cdot \text{cm}^{-3}$.
4 However, it should be noted that the concentration of water in the troposphere is abundant, and DSA
5 is easily hydrolyzed to form H_2SO_4 . Based on this, the concentration of DSA listed in Fig. S9 was
6 overestimated. However, the extent and proportion of DSA hydrolysis remains unclear, and the
7 hydrolysis behavior of DSA needs to be further investigated in subsequent studies. Therefore, the
8 maximum concentration of DSA (10^8 molecules $\cdot \text{cm}^{-3}$) was not included in the effect of $\text{H}_2\text{S}_2\text{O}_7$, the
9 product of the reaction between SO_3 and H_2SO_4 , on new particle formation (NPF) in various
10 environments by using the Atmospheric Cluster Dynamics Code kinetic model and the QC
11 calculation. In Lines 27-29 Page 7 to Lines 1-2 Page 8 of the revised manuscript, the discussion of
12 the DSA concentration has been added as “As the prediction in Table S7, the concentration of DSA
13 is set to 10^4 - 10^8 molecules $\cdot \text{cm}^{-3}$. However, DSA is easily hydrolyzed with abundant water in the
14 troposphere to form H_2SO_4 , the concentration of DSA listed in Fig. S9 was overestimated. So, the
15 maximum concentration of DSA (10^8 molecules $\cdot \text{cm}^{-3}$) was not included in the effect of $\text{H}_2\text{S}_2\text{O}_7$ on
16 new particle formation (NPF) in various environments.”

17 Overall, the $\text{SO}_3 + \text{SA}$ reaction cannot compete with H_2O -assisted hydrolysis of SO_3 within the
18 altitude range of 0-30 km in the Earth's atmosphere, even considering of high H_2SO_4 concentration
19 at the end and outside the aircraft engine and flight. However, the $\text{SO}_3 + \text{SA}$ reaction is significantly
20 more favorable than the hydrolysis reaction of $\text{SO}_3 + (\text{H}_2\text{O})_2$ within the altitude range of 40-70 km
21 in Venus' atmosphere. Moreover, as the extent and proportion of DSA hydrolysis is unclear, the
22 maximum concentration of DSA (10^8 molecules $\cdot \text{cm}^{-3}$) was not included in the effect of $\text{H}_2\text{S}_2\text{O}_7$ on
23 new particle formation (NPF) in various environments by using the Atmospheric Cluster Dynamics
24 Code kinetic model and the QC calculation.

25

26 **Comment 5.**

27 Another issue to consider is the timescale associated with participation in NPF of compounds with
28 mixing ratios well below a part per quadrillion. The gas-kinetic bimolecular collision rate for small
29 molecules and their clusters is around $1\text{E}-10$... $1\text{E}-9$ cm^3 per molecule and second. If the DSA
30 concentration is 1 molecule per cm^3 , then on average a H_2SO_4 molecule, or a H_2SO_4 -containing

1 cluster, will thus collide with DSA molecules about once per 1E9 seconds or so (as the pseudo-
2 unimolecular collision rate is k_{coll} times the concentration, and the lifetime with respect to
3 collisions is the inverse of this). This is more than 30 YEARS. Even for a DSA concentration of 10
4 per cm^3 , the timescale of a given molecule or cluster colliding with a DSA molecule is more than 3
5 YEARS. Or for 100 per cm^3 , more than 3 months. It is quite clear from this that the pseudo-steady-
6 state assumed by ACDC simulations will simply never have time to form, when some of the
7 participating molecules have such low concentrations. Or in other words, the basic assumptions
8 required for modelling clustering with ACDC do not apply in these cases (or, to put it yet another
9 way, an ACDC - type code needs to be run in a very different way, explicitly accounting for these
10 timescales).

11 **Response:** Thanks for your valuable comments. We agree with the reviewer that at some of the
12 participating molecules such low concentrations that the pseudo-steady-state assumed by ACDC
13 simulations will simply never have time to form. Based on this, Considering the concentration of
14 sulfuric acid at the end and outside the aircraft engine and flight (up to 600 pptv), the concentration
15 of $\text{H}_2\text{S}_2\text{O}_7$ has been re-evaluated within the altitude range of 0-30 km. Specifically, the steady-state
16 concentration of DSA was calculated using the calculated equilibrium constant listed in Eq. S5.

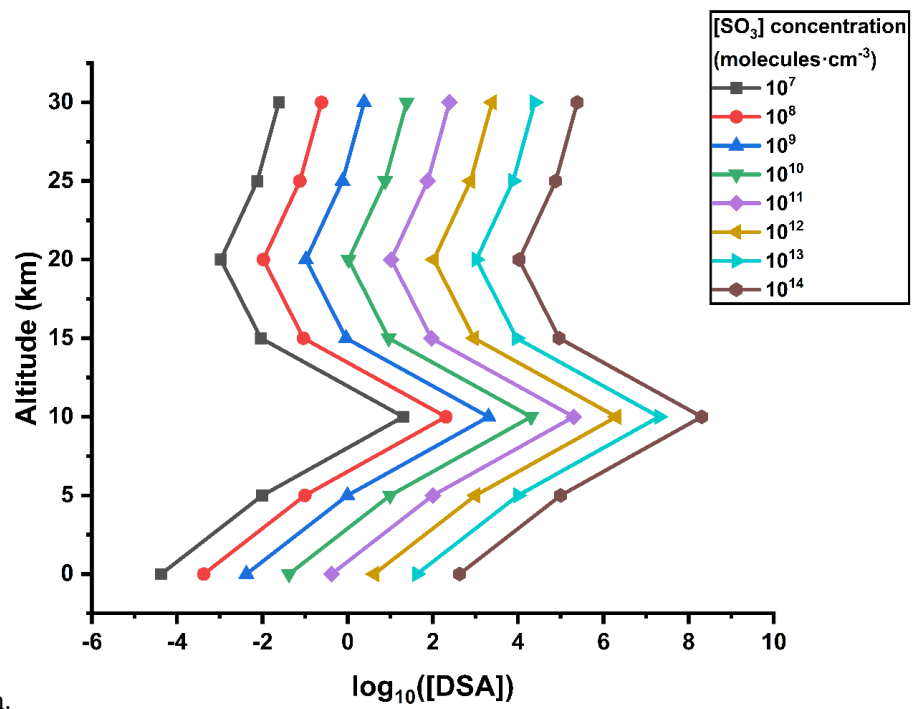

$$17 \quad K_{\text{eq}3} = \frac{[\text{DSA}]}{[\text{SO}_3][\text{SA}]} \quad (\text{S5})$$

18 where $K_{\text{eq}3}$ is the equilibrium constant of DSA with respect to SO_3 and H_2SO_4 within the altitude
19 range of 0-30 km shown in Table S9; $[\text{SO}_3]$, $[\text{SA}]$ and $[\text{DSA}]$ are the concentrations of SO_3 , H_2SO_4 ,
20 and $\text{H}_2\text{S}_2\text{O}_7$, respectively. Although the concentration of sulfur trioxide remains unknown at
21 different altitudes, experimental observations have shown that the concentration of sulfur trioxide
22 can reach 10^6 molecules cm^{-3} in the troposphere. Moreover, water vapor concentrations significantly
23 decrease with increasing of altitude. Consequently, the concentration of sulfur trioxide should be
24 higher in the stratosphere than in the troposphere, and its concentration would increase as a result
25 of geoengineered injection of SO_2 or SO_3 . Besides, it is worth noting that H_2SO_4 can form at the
26 end and outside the engine, and flight measurements in the exhaust plume have measured sulfuric
27 acid abundances up to a value of 600 pptv. When an average flight altitude of 10 km is considered,
28 this corresponds to a concentration of 5.1×10^9 molecules $\cdot \text{cm}^{-3}$. Therefore, we have calculated the
29 concentrations of DSA according to concentrations of sulfur trioxide in the range from 10^7 to 10^{14}

1 molecules cm^{-3} and the concentrations of H_2SO_4 in the range of 10^4 - 10^9 molecules cm^{-3} as shown
2 in Fig. S9.

3 The maximum concentration of DSA displayed in Fig. S9 can be up to 10^8 molecules $\cdot \text{cm}^{-3}$.

4 However, it should be noted that the concentration of water in the troposphere is abundant, and
5 DSA is easily hydrolyzed to form H_2SO_4 . Based on this, the concentration of DSA listed in Fig. S9
6 was overestimated. The extent and proportion of DSA hydrolysis remains unclear, and the
7 hydrolysis behavior of DSA needs to be further investigated in subsequent studies. Therefore, the
8 maximum concentration of DSA (10^8 molecules $\cdot \text{cm}^{-3}$) was not included in the effect of $\text{H}_2\text{S}_2\text{O}_7$,
9 the product of the reaction between SO_3 and H_2SO_4 , on new particle formation (NPF) in various
10 environments by using the Atmospheric Cluster Dynamics Code kinetic model and the QC

11 calculation.

12 **Fig. S9** Concentration (unit: molecules $\cdot \text{cm}^{-3}$) of DSA with respect to different concentrations of SO_3
13 as function of altitude. We consider the possible concentrations of SO_3 with the injection of SO_3 .

14
15 The maximum concentration of DSA displayed in Fig. S9 can be up to 10^8 molecules $\cdot \text{cm}^{-3}$.
16 However, it should be noted that the concentration of water in the troposphere is abundant, and DSA
17 is easily hydrolyzed to form H_2SO_4 . Based on this, the concentration of DSA listed in Fig. S9 was
18 overestimated. The extent and proportion of DSA hydrolysis remains unclear, and the hydrolysis
19 behavior of DSA needs to be further investigated in subsequent studies. Therefore, the maximum
20 concentration of DSA (10^8 molecules $\cdot \text{cm}^{-3}$) was not included in the effect of $\text{H}_2\text{S}_2\text{O}_7$, the product of

1 the reaction between SO₃ and H₂SO₄, on new particle formation (NPF) in various environments by
2 using the Atmospheric Cluster Dynamics Code kinetic model and the QC calculation.

3 4 **Technical issues**

5 **Comment 6.**

6 The kinetic approach used here seems quite elaborate, given that the authors are not actually treating
7 (or at least not discussing) any sort of pressure dependence, non-thermalisation, etc. How different
8 are the rates compared to what one would obtain using a simple transition state theory framework
9 (plus assuming kinetic gas theory forward rates for the initial complex formation)? I'm not
10 criticising the use of elaborate methods as such, I'm just trying to assess how much difference they
11 make, compared to a much simpler approach.

12 **Response:** Thanks for your valuable comments. The Rice-Ramsperger-Kassel-Marcus based
13 Master Equation (ME/RRKM) model is well suited to calculate the kinetics of the SO₃ + H₂SO₄
14 reaction without and with H₂O. Specifically, as for the SO₃ + H₂SO₄ → H₂S₂O₇ reaction without
15 and with H₂O illustrated in Fig. 1, the reaction without H₂O has only a barrier height of 2.3 kcal·mol⁻¹
16 to produce the formation of H₂S₂O₇, while the reaction with H₂O only has a lower barrier height
17 of 0.5 kcal·mol⁻¹. It is reported that the ME/RRKM model has been used widely to calculate the rate
18 constants of many gas phase reactions (*J. Am. Chem. Soc.*, 2022, 144, 19910-19920.; *J. Am. Chem.*
19 *Soc.*, 2022, 144, 20, 9172-9177.; *Phys. Chem. Chem. Phys.*, 2022, 24, 18205-18216.; *Phys. Chem.*
20 *Chem. Phys.*, 2022, 24, 4966-4977.; *J. Phys. Chem. A*, 2019, 123, 3131-3141.; *Chem. Phys. Lett.*,
21 2020, 742, 137157.) where the rate constants for barrierless or near barrierless bimolecular reactions
22 were evaluated reliably. In this case, the pre-equilibrium approximation used in our calculation is
23 truly obsolete and may not be appropriate.

24 Meanwhile, to check the reliability of Master Equation (ME/RRKM) model, the rate constants
25 for the SO₃ + H₂SO₄ reaction without and with H₂O were also calculated by using transition state
26 theory (TST) coupled with the pre-equilibrium approximation. As seen in Table S6, the rate
27 constants for the SO₃ + H₂SO₄ reaction without and with H₂O by using transition state theory is
28 significantly higher than the gas kinetic limit. In addition, as for the rate constants calculated by
29 transition state theory (TST) coupled with the pre-equilibrium approximation, the rate constants for
30 the SO₃ + H₂SO₄ reaction without and with H₂O showed appreciably high negative temperature

1 dependence making the rate constants even larger at lower temperatures. This reveals that the TST
 2 coupled with pre-equilibrium approximation used in our calculation is truly obsolete and may not
 3 be appropriate. Thus, Using the Master Equation/Rice-Ramsperger-Kassel-Marcus (ME/RRKM)
 4 models, the kinetic calculations for the SO₃ + H₂SO₄ reaction without and with H₂O were performed
 5 by Barts-Widom method in the MESMER program package (Master Equation Solver for Multi-
 6 Energy Well Reactions).

7 **Table S6** The rate constant (cm³·molecule⁻¹·s⁻¹) for the SO₃ + H₂SO₄ reaction for the SO₃ + H₂SO₄
 8 reaction without and with H₂O within the temperature range of 280-320 K by using transition state
 9 theory

<i>T</i> /(K)	280 K	290 K	298 K	300 K	310 K	320 K
<i>k</i> _{DSA}	8.98 × 10 ⁻⁹	4.38 × 10 ⁻⁹	2.56 × 10 ⁻⁹	2.25 × 10 ⁻⁹	1.20 × 10 ⁻⁹	6.72 × 10 ⁻¹⁰
<i>k'</i> _{DSA_WM_o}	5.77 × 10 ⁻⁸	2.59 × 10 ⁻⁸	1.42 × 10 ⁻⁸	1.23 × 10 ⁻⁸	6.12 × 10 ⁻⁹	3.18 × 10 ⁻⁹
<i>k'</i> _{DSA_WM_s}	5.20 × 10 ⁻⁵	2.44 × 10 ⁻⁵	1.39 × 10 ⁻⁵	1.21 × 10 ⁻⁵	6.29 × 10 ⁻⁶	3.42 × 10 ⁻⁶

10 *k*_{DSA} is the rate constant for the SO₃ + H₂SO₄ reaction; *k*_{DSA_WM_o} and *k*_{DSA_WM_s} are respectively the rate constants
 11 for H₂O-assisted SO₃ + H₂SO₄ reaction occurring through one-step and stepwise routes.

12
 13 **Comment 7**

14 The method references for M06-2X, CCSD(T)-F12, and the ORCA program are not correct - the
 15 first is completely wrong, while the latter refer to studies which have also used these approaches.
 16 Please refer to the actual publications introducing the methods/codes instead.

17 **Response:** Thanks for your valuable comments. We are very sorry for using wrong references for
 18 M06-2X, CCSD(T)-F12, and the ORCA program. The references regarding for the M06-2X,
 19 CCSD(T)-F12 and the ORCA program has been respectively made as follows.

20 (a) As for M06-2X method, the correct references have been recited which has been organized
 21 as references (Zhao and Truhlar, 2008; Elm et al., 2012).
