

1 **Responses to Referee #2's comments**

2 We are grateful to the reviewers for their valuable and helpful comments on our manuscript
3 "Reaction of SO₃ with H₂SO₄ and Its Implication for Aerosol Particle Formation in the Gas Phase
4 and at the Air-Water Interface" (MS No.: **egusphere-2023-2009**). We have revised the manuscript
5 carefully according to reviewers' comments. The point-to-point responses to the Referee #2's
6 comments are summarized below:

7

8 **Referee Comments**

9 Using computational methods Wang and co-workers study the reaction between H₂SO₄ and
10 SO₃ leading to the formation of H₂S₂O₇. The gas-phase formation mechanism is studied using
11 well-established methodologies, both with and without a water molecule present. The reaction is
12 also studied at the air-water interface using Born-Oppenheimer molecular dynamics simulations.
13 Finally, the authors study the potential of the formed H₂S₂O₇ product in "enhancing" new particle
14 formation involving sulfuric acid and ammonia.

15 Overall, the applied quantum chemical methods are up to the current standard and the study is
16 broadly atmospherically interesting, but I believe many of the conclusions are erroneously drawn
17 and not supported by the data. Remember negative results are equally as important as positive
18 results. So try to frame the results in a more transparent fashion. In addition, there is heavy
19 referencing to the SI, which makes the paper difficult to follow in some places and the reader is
20 left wondering if the claims are actually correct. I believe the paper might be worth publishing, but
21 some critical changes must be made.

22 **Response:** We would like to thank the reviewer for the positive and valuable comments, and we
23 have revised our manuscript accordingly.

24

25 **Specific Comments:**

26 **Comment 1.**

27 **Overall:** When referring to the SI, please add the numbers to the text as well and elaborate on
28 what the reader is supposed to look at in the SI. In several places it is very difficult to comprehend
29 how the authors draw the conclusions.

1 **Response:** Thanks for your valuable comments. According to the reviewer's suggestion, the
2 numbers have been added to the manuscript in reference to the SI and detailing what the reader
3 should look for in the SI. The corresponding revision has been respectively made as follows.

4 (a) In Lines 18-19 Page 5 of the revised manuscript, the optimized structures and the
5 formation Gibbs free energy of the stable clusters in the supporting information has been
6 mentioned and organized as “The optimized structures and the formation Gibbs free energy of the
7 stable clusters were summarized in Fig. S9 and Table S8 of the *SI Appendix*, respectively.”

8 (b) In Lines 18-19 Page 5 of the revised manuscript, the details of the equilibrium process
9 for the droplet system with 191 water molecules in the supporting information has been mentioned
10 and organized as “The details of the equilibrium process for the droplet system with 191 water
11 molecules are shown in the *SI Appendix Part 4*.”

12 (c) In Lines 10-12 Page 9 of the revised manuscript, the details for calculations of effective
13 rate constants in the supporting information has been mentioned and organized as “the effective
14 rate constants for two bimolecular reactions of $\text{H}_2\text{SO}_4 \cdots \text{H}_2\text{O} + \text{SO}_3$ and $\text{SO}_3 \cdots \text{H}_2\text{O} + \text{H}_2\text{SO}_4$ were
15 calculated, and the details were shown in *SI Appendix, Part 3 and Table 1*.”

16

17 **Comment 2.**

18 **Line 48:** “As a typical inorganic acid, SA can act as an important role in the new particle
19 formation ...”

20 What is meant by “typical here? Please rephrase this sentence.

21 **Response:** Thanks for your valuable comments. It has been reported that H_2SO_4 is a major
22 inorganic acidic air pollutant (*Atmos. Chem. Phys.*, 2011, 11, 10803-10822.; *Atmos. Chem. Phys.*,
23 2021, 21, 13483-13536.). So, according to the reviewer's suggestion, “As a typical inorganic acid,
24 SA can act as an important role in the new particle formation...” has been changed as “As a major
25 inorganic acidic air pollutant (Tilgner et al., 2021), SA can act as an important role in the new
26 particle formation...”.

27

28 **Comment 3.**

29 **Line 82:** “It has been shown that the products of SO_3 with some important atmospheric species
30 have been identified in promoting NPF process.”

1 Such reaction would lead to the consumption of an SO₃ molecule potentially at the expense of
2 forming less sulfuric acid. This competition should be further discussed in the manuscript.

3 **Response:** Thanks for your valuable comments. According to the reviewer's suggestion, the
4 sentence of "It has been shown that the reaction between SO₃ and some important atmospheric
5 species (Li et al., 2018a; Yang et al., 2021; Liu et al., 2019; Rong et al., 2020) not only can cause
6 appreciable consumption of SO₃ and thus reduce the abundance of SA from the hydrolysis of SO₃
7 in the atmosphere, but also can promote NPF process by their products." has been added in Lines
8 1-4 Page 4 of the revised manuscript. Moreover, to study the atmospheric importance of the SO₃ +
9 H₂SO₄ reaction without and with H₂O, the rate ratio ($v_{\text{DSA}}/v_{\text{SA}}$) between the SO₃ + H₂SO₄ reaction
10 and H₂O-assisted hydrolysis of SO₃ was compared which has been organized in Lines 13-29 Page
11 13 to Lines 1-11 Page 14.

12 13 **Comment 4.**

14 **Line 104:** I am missing some justification to why the M06-2X functional has been used and why
15 the 6-311++G(2df,2pd) basis set was chosen. In addition, the M06-2X reference is incorrect.

16 **Response:** Thanks for your valuable comments. According to the reviewer's suggestion, the
17 reason that M06-2X method with 6-311++G(2df,2pd) basis set has been added as follows.

18 (a) It has been proved that M06-2X functional is one of the best functionals to describe the
19 noncovalent interactions and estimate the thermochemistry and equilibrium structures for
20 atmospheric reactions. In Lines 22-24 Page 4 of the revised manuscript, the sentence of "The
21 M06-2X functional has been proved to be one of the best functionals to describe the noncovalent
22 interactions and estimate the thermochemistry and equilibrium structures for atmospheric
23 reactions." has been added.

24 (b) The geometric parameters of the SO₃ and H₂SO₄ reactants calculated at the M06-2X/6-
25 311++G(3df,2pd) level have been shown in Fig. S1. As seen in Fig. S1, the mean absolute
26 deviation of calculated bond distances and bond angles between the M06-2X/6-311++G(3df,2pd)
27 level and the experimental reports were 0.005 Å and 0.45°, respectively. This reveals that the
28 calculated bond distances and bond angles at the M06-2X/6-311++G(3df,2pd) level agree well
29 with the available experimental values. So, the method of M06-2X/6-311++G(3df,2pd) was
30 reliable to optimize the geometries of all the stationary points in the SO₃ + H₂SO₄ reaction without

1 and with H₂O. The corresponding details revision have been shown in Fig. S1. Thus, in Lines 1-2
2 Page 4 of the revised manuscript, the sentence of “It is noted that the calculated bond distances
3 and bond angles at the M06-2X/6-311++G(3df,2pd) level (Fig. S1) agree well with the available
4 experimental values.” has been added.

5
6 **Fig. R1** The optimized geometrical structures for the species of the SO₃ and HCl at M06-2X/6-
7 311++G(3df,2pd) level of theory. The values in parentheses are the experimental values. Bond
8 length is in angstrom and angle is in degree.

9 (c) As for M06-2X method, the correct references have been recited which has been
10 organized as references (Zhao and Truhlar, 2008; Elm et al., 2012).

11 [1] Zhao, Y., and Truhlar, D. G.: The M06 suite of density functionals for main group
12 thermochemistry, thermochemical kinetics, noncovalent interactions, excited states, and transition
13 elements: two new functionals and systematic testing of four M06-class functionals and 12 other
14 functionals, *Theor. Chem. Acc.*, 120, 215-241, 2008.;

18

19 **Comment 5.**

20 **Line 108:** The ORCA reference is incorrect.

21 **Response:** Thanks for your valuable comments. We are very sorry for using wrong references for
22 the ORCA program. As for ORCA program, the corresponding reference have been recited and
23 organized as references (Neese, 2012).

24 [1] Neese, F.: The ORCA program system, *WIREs Comput. Mol. Sci.*, 2, 73-78,
25 <https://doi.org/10.1002/wcms.81>, 2012.

1

2 **Comment 6.**

3 **Line 110-116:** I am in doubt whether the applied configurational sampling of the clusters is
4 sufficient to identify the lowest free energy cluster structures. Only calculating 1000 local minima
5 from the ABCcluster search sounds a bit low on the low side. How certain are the authors that they
6 have located the global minimum? As the CHARMM forcefield cannot handle bond breaking a
7 more diverse pool of clusters is needed. This is usually done by performing ABCcluster runs with
8 ionic monomers as well (see Kubečka et al., <https://doi.org/10.1021/acs.jpca.9b03853>). Only
9 selecting the lowest 100 cluster configurations based on PM6 could lead to the global minimum
10 cluster being missed (see Kurfman et al., <https://doi.org/10.1021/acs.jpca.1c00872>).

11 **Response:** Thanks for your valuable comments. We are very sorry for missing a ‘*n*’ for the
12 configurational sampling method. Indeed, a multi-path searching approach is adopted in this work,
13 which expands the search range. As for every global minimum cluster, *n* kinds of searching
14 pathways have been considered, and 1000 autogenerated structures in every searching pathway
15 were first carried out using ABCcluster software, and were optimized at the semi-empirical PM6
16 methods using MOPAC 2016. Then, up to *n**100 structures with relatively lowest energy among
17 the *n**1000 ($1 < n < 5$) structures were selected and reoptimized at the M06-2X/6-31+G(*d,p*) level.
18 Finally, *n**10 lowest-lying structures were optimized by the M06-2X/6-311++G(2*df*,2*pd*) level to
19 determine the global minimum. So, the method for configurational sampling of the clusters has
20 been corrected as “Specifically, a multistep global minimum sampling technique was used to
21 search for the global minima of the (SA)_{*x*}(A)_{*y*}(DSA)_{*z*} ($0 < y \leq x + z \leq 3$) clusters. Specifically, the
22 initial *n**1000 ($1 < n < 5$) configurations for each cluster were systematically generated by the
23 ABCcluster program (Zhang and Dolg, 2015), and were optimized at the semi-empirical PM6
24 (Stewart, 2013) methods using MOPAC 2016 (Stewart, 2013; Stewart, 2007). Then, up to *n**100
25 structures with relatively lowest energy among the *n**1000 ($1 < n < 5$) structures were selected and
26 reoptimized at the M06-2X/6-31+G(*d,p*) level. Finally, *n**10 lowest-lying structures were
27 optimized by the M06-2X/6-311++G(2*df*,2*pd*) level to determine the global minimum. The
28 optimized structures and the formation Gibbs free energy of the stable clusters were summarized
29 in Fig. S9 and Table S8 of the SI Appendix, respectively.” in Line 8-19 Page 5 of the revised
30 manuscript.

1

2 **Comment 7.**

3 **Line 116:** Here it is stated that the free energies are calculated at the M06-2X/6-311++G(2df,2pd)
4 level of theory. However, Table S8 indicates that DLPNO-CCSD(T) single point energy
5 calculations were carried out on top of the clusters.

6 **Response:** Thanks for your valuable comments. We apologize for the reviewer's
7 misunderstanding of the calculation methodology. Indeed, the M06-2X/6-311++G(2df,2pd)
8 method has been used to optimize the geometries of (DSA)_x(SA)_y(A)_z ($z \leq x + y \leq 3$) molecular
9 clusters, while the single-point energy calculations were refined at the DLPNO-CCSD(T)/aug-cc-
10 pVTZ level based on the optimized geometries at the M06-2X/6-311++G(2df,2pd) level. In order
11 to express the calculated method clearly, in Lines 16-18 Page 5 of the revised manuscript, the
12 sentence of "To obtain the reliable energies, single-point energy calculations were refined at the
13 DLPNO-CCSD(T)/aug-cc-pVTZ level based on the optimized geometries at the M06-2X/6-
14 311++G(2df,2pd) level" has been added.

15

16 **Comment 8.**

17 **Line 147:** How was the 191 water cluster obtained? Has this cluster been equilibrated before the
18 SO₃ and H₂SO₄ was added? Or after? Some more details about how the system was setup is
19 needed. Is a 1 fs timestep adequate to capture the desired dynamics? I.e. can it actually capture the
20 hydrogen bond stretching vibration?

21 **Response:** Thanks for your valuable comments. According to the reviewer's suggestion, the
22 reason for selecting the droplet system with 191 water molecules has been explained firstly.
23 Meanwhile, it is pointed out that the droplet system with 191 water molecules has been
24 equilibrated before SO₃ and H₂SO₄ was added at the water surface. Finally, the reason for setting a
25 1 fs timestep in the dynamic simulations has been explained. The corresponding revision has been
26 respectively made as follows.

27 (a) The size effect on interfacial mechanism has been reported by Zhong et al. (*J. Am. Chem.*
28 *Soc.*, 2017, 139, 47, 17168-17174), where the behavior of SO₂ adsorption on droplet with 24, 48,
29 96 and 191 water molecules has been studied. The work reported by Zhong et al. (*J. Am. Chem.*
30 *Soc.*, 2017, 139, 47, 17168-17174) shows that the smaller droplet is subjected to large deformation

1 during the system evolution, and the droplet system with 191 water molecules are sufficient to
2 describe the interfacial mechanism. So, we only consider the droplet system with 191 water
3 molecules in the BOMD simulation. The radius of the water droplet in our system was
4 approximately 10.7 Å and a cubic simulation box of side 35 Å was used. The similar set of
5 simulation box have been found widely in previous works. (*J. Am. Chem. Soc.*, 2016, 138, 1816-
6 1819; *Proc. Natl. Acad. Sci. U.S.A.*, 2017, 114, 12401-12406.; *J. Am. Chem. Soc.*, 2018, 140, 6456-
7 6466.; *J. Am. Chem. Soc.*, 2018, 140, 14, 4913-4921.; *Chem. Sci.*, 2019, 10, 743-751.; *Chem. Sci.*,
8 2017,8, 5385-5391.). So, in Lines 20-22 Page 6 of the revised manuscript, the droplet system with
9 191 water molecules has been reorganized as “As the droplet system with 191 water molecules are
10 sufficient to describe the interfacial mechanism, the air-water interfacial system here included 191
11 water molecules, SO₃ and SA in the BOMD simulation.”.

12 (b) The droplet system with 191 water molecules has been equilibrated before SO₃ and
13 H₂SO₄ was added at the water surface. Specifically, a nearly spherical droplet with 191 water
14 molecules was firstly constructed by using the Packmol program (*J. Comput. Chem.*, 2009, 30,
15 2157-2164.) with a tolerance of 2.0 Å, namely, all atoms from different molecules will be at least
16 2.0 Å apart. Then, based on the resulting initial structure, the GROMACS software (*J. Comput.*
17 *Chem.*, 2005, 26, 1701-1718.) with the general AMBER force field (GAFF) (*J. Comput. Chem.*
18 2004, 25, 1157-1174.) was used to simulate the droplet equilibrium process with two steps. In the
19 first step, a water slab of 35 × 35 × 35 Å³ containing 191 water molecules was built using periodic
20 boundary conditions to avoid the effect of neighboring replicas. In the second step, the water slab
21 was fully equilibrated for 1 ns under NVT ensemble (N, V and T represent the number of atoms,
22 volume and temperature, respectively) to reach equilibrium state. The water molecules were
23 described by the TIP3P model. The isothermal-isochoric (NVT) simulation was executed at 298 K
24 for simulation system. The temperature was kept constant by the V-rescale thermostat coupling
25 algorithm. The coupling time constant is 0.1 ps. Bond lengths were constrained by the LINCS
26 algorithm. The cut-off distance of 1.2 nm was set for van der Waals (vdW) interactions. The
27 Particle Mesh Ewald (PME) summation method was used to calculate the electrostatic interactions.
28 During the whole simulation process, a time step of 2 fs was set and three-dimensional periodic
29 boundary conditions were adopted. Next, to ensure the stability of the system, the droplets were
30 pre-optimized using BOMD at 300 K for 10 ps prior to the simulation of the air-water interfacial

1 reaction. Using the density functional theory (DFT) method, the electronic exchange-correlation
2 term was described by the Becke-Lee-Yang-Parr (BLYP) functional. The Grimme's dispersion
3 correction (D3) was applied to account for the weak dispersion interaction. The double- ζ Gaussian
4 (DZVP-MOLOPT) basis set and the Goedecker-Teter-Hutter (GTH) norm-conserving
5 pseudopotentials were adopted to treat the valence and the core electrons, respectively. The
6 planewave cutoff energy is set to 280 Ry, and that for the Gaussian basis set is 40 Ry. And the
7 SCF convergence criterion is 1.0E-5 Hartree. All simulations were performed in NVT ensemble
8 with Nose-Hoover thermostat controlling the temperature. Finally, the SO₃ and H₂SO₄ molecule
9 was added at the water surface after the droplet system with 191 water molecules was fully
10 equilibrated. The details of the equilibrium process for the droplet system with 191 water
11 molecules are shown in the *SI Appendix* Part 4. Meanwhile, the sentence of “It is pointed out that
12 the droplet system with 191 water molecules has been equilibrated before SO₃ and H₂SO₄ was
13 added at the water surface. The details of the equilibrium process for the droplet system with 191
14 water molecules are shown in the *SI Appendix* Part 4.” has been added in Lines 22-25 Page 6 of
15 the revised manuscript.

16 (c) In the interfacial BOMD simulations, the timestep was set to be 1.0 fs, as it has been
17 proved to achieve sufficient energy conservation for the water system (*J. Chem. Theory Comput.*,
18 2011, 7, 2937-2946.; *J. Am. Chem. Soc.* 2015, 137, 12070.; *J. Am. Chem. Soc.* 2016, 138, 1816.; *J.*
19 *Am. Chem. Soc.* 2016, 138, 11164.; *Chem. Sci.* 2017, 8, 5385.). So, the sentence of “Notably, the
20 timestep of 1.0 fs has been proved to achieve sufficient energy conservation for the water system.”
21 has been added in Lines 27-28 Page 6 of revised manuscript.

22

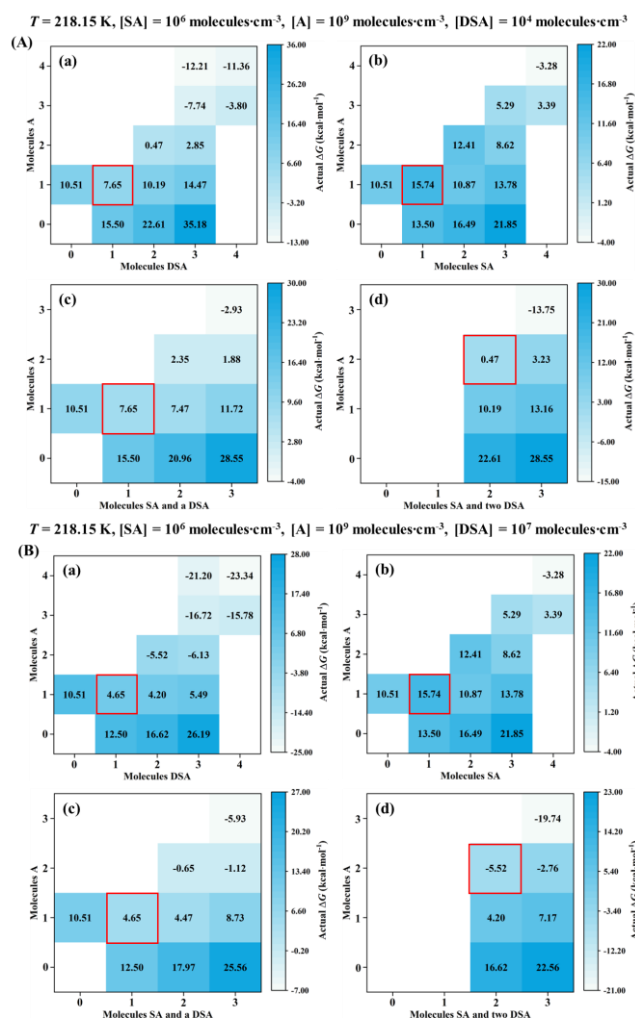

23 **Comment 9.**

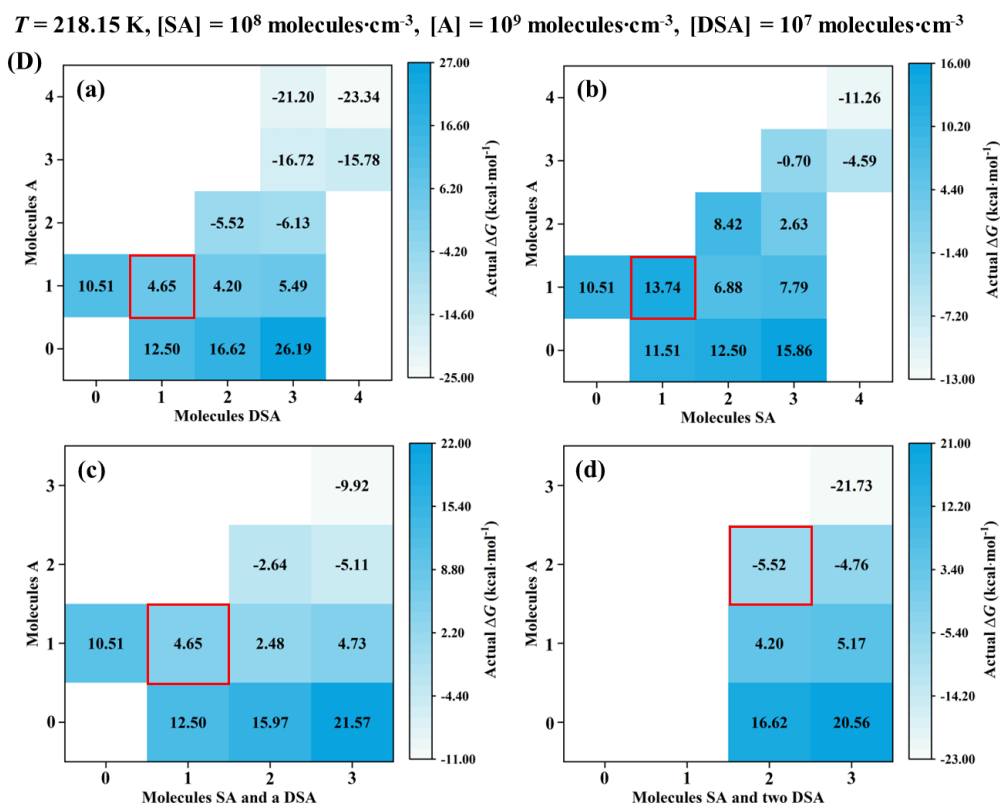

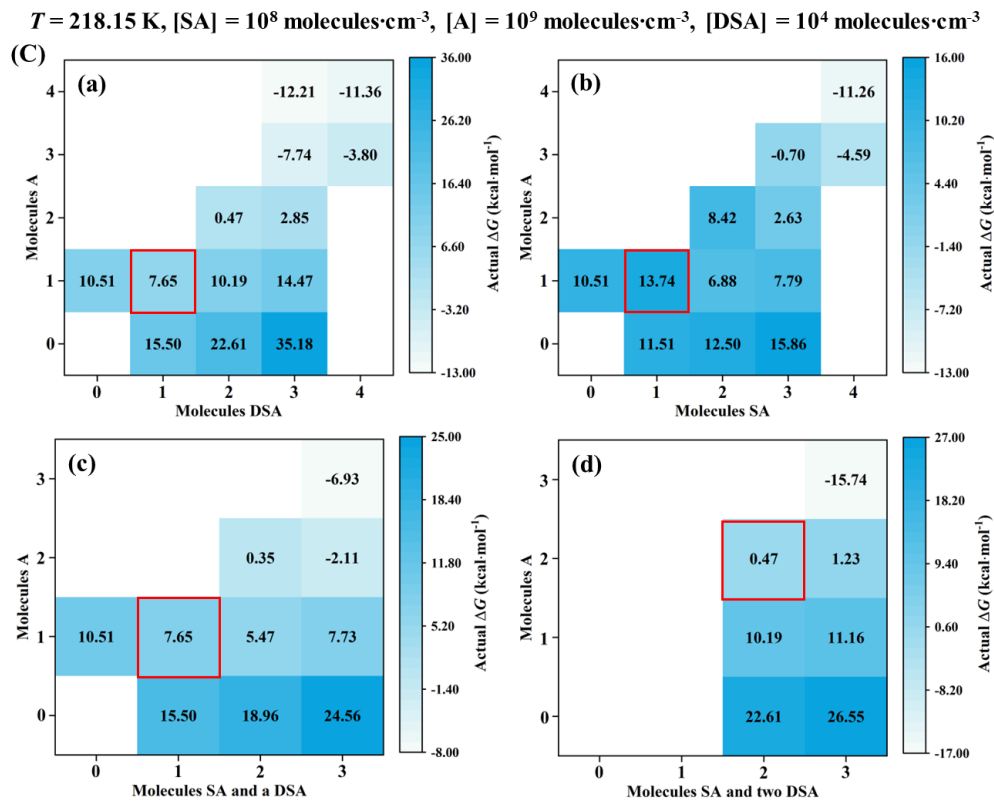

24 **Line 156:** I am not entirely convinced that the 3 × 3 system “box” size is large enough to ensure
25 meaningful cluster dynamics of the systems. For instance, the work by Besel et al.
26 (<https://doi.org/10.1021/acs.jpca.0c03984>) showed how the sulfuric acid-ammonia system is
27 impacted by the studied box size. Please elaborate on this aspect.

28 Also is the sulfur concentration constrained in the simulations? A single DSA molecule would
29 consume 2 sulfuric acids. 1 SA and 1 SO₃ that could form SA. Hence, the simulations might
30 actually “push” additional sulfur into the system.

1 **Response:** Thanks for your valuable comments. For reviewers' comments, the corresponding
 2 revision has been respectively made as follows.

3 (a) As the work reported by Besel et al. (*J. Phys. Chem. A*, **2020**, 124(28), 5931-5943), the
 4 explicitly simulated set of clusters should always include the “critical cluster”. Also, the highest
 5 barrier on the lowest-energy path connecting the monomers to the outgrowing clusters (a saddle
 6 point on the actual ΔG surface) represents the “critical cluster”. So, at 218.15 K (Fig. S12) and
 7 238.15 K (Fig. S13), the actual ΔG of $(A)_y(DSA)_z$ ($0 \leq y \leq z \leq 4$), $(SA)_x(A)_y$ ($0 \leq y \leq x \leq 4$),
 8 $(SA)_x(A)_y(DSA)_1$ ($0 \leq y \leq 3, 0 \leq x \leq 2$), and $(SA)_x(A)_y(DSA)_2$ ($0 \leq y \leq 3, 0 \leq x \leq 1$) clusters has
 9 been calculated to ensure meaningful cluster dynamics of the 3×3 systems. As seen in Fig. S12
 10 and S13, the actual ΔG surface represented that the simulated set of clusters always included the
 11 critical cluster. So, we conclude that, in atmospherically relevant conditions, a 3×3 cluster set is
 12 adequate for predicting the particle formation in the SA-A system.

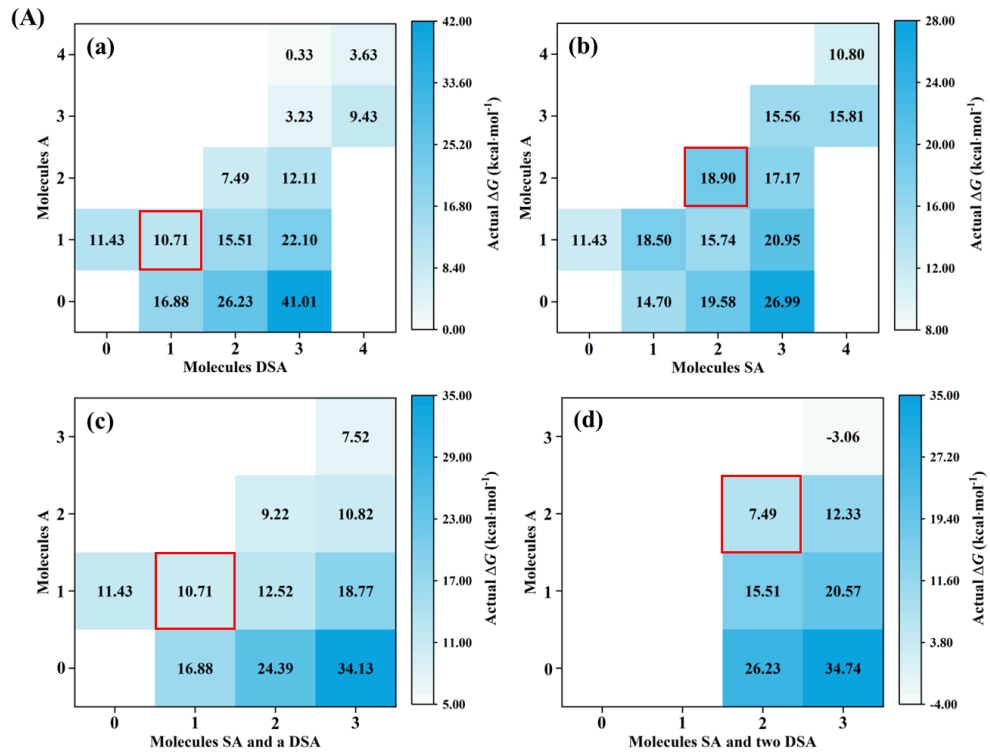

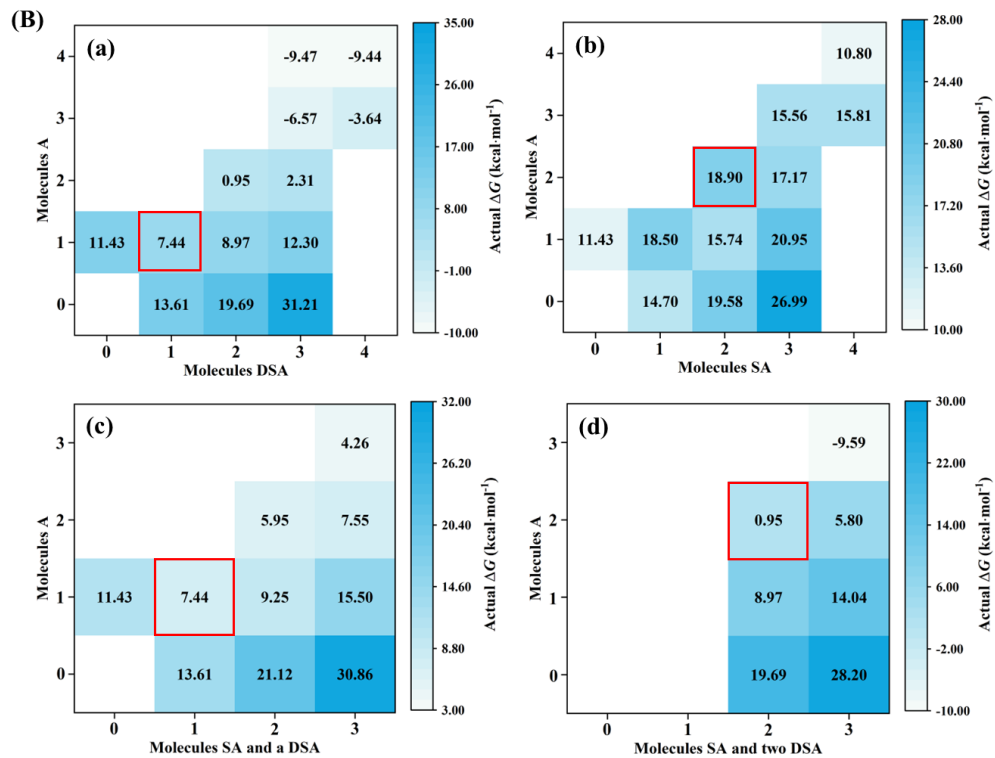

1
2
3

Fig. S12 A typical actual ΔG surface at 218.15 K. $[\text{SA}]$ is the concentration of sulfuric acid monomers, $[\text{A}]$ the concentration of ammonia monomers and $[\text{DSA}]$ is disulfuric acid

$T = 238.15 \text{ K}$, $[\text{SA}] = 10^6 \text{ molecules}\cdot\text{cm}^{-3}$, $[\text{A}] = 10^9 \text{ molecules}\cdot\text{cm}^{-3}$, $[\text{DSA}] = 10^4 \text{ molecules}\cdot\text{cm}^{-3}$

$T = 238.15 \text{ K}$, $[\text{SA}] = 10^6 \text{ molecules}\cdot\text{cm}^{-3}$, $[\text{A}] = 10^9 \text{ molecules}\cdot\text{cm}^{-3}$, $[\text{DSA}] = 10^7 \text{ molecules}\cdot\text{cm}^{-3}$

$T = 238.15 \text{ K}$, $[\text{SA}] = 10^8 \text{ molecules}\cdot\text{cm}^{-3}$, $[\text{A}] = 10^9 \text{ molecules}\cdot\text{cm}^{-3}$, $[\text{DSA}] = 10^4 \text{ molecules}\cdot\text{cm}^{-3}$

$T = 238.15 \text{ K}$, $[\text{SA}] = 10^8 \text{ molecules}\cdot\text{cm}^{-3}$, $[\text{A}] = 10^9 \text{ molecules}\cdot\text{cm}^{-3}$, $[\text{DSA}] = 10^7 \text{ molecules}\cdot\text{cm}^{-3}$

1

2 **Fig. S13** A typical actual ΔG surface at 238.15 K. $[\text{SA}]$ is the concentration of sulfuric acid
 3 monomers, $[\text{A}]$ the concentration of ammonia monomers and $[\text{DSA}]$ is disulfuric acid

4 (b) As mentioned by the reviewer, each DSA molecule generated consumes one SA molecule,
 5 resulting the simulations might “push” additional sulfur into the system. So, when the sum ($[\text{SA}] +$

1 [DSA]) is kept constant ($10^4 - 10^8$ molecules·cm⁻³), Fig. S19 shows particle formation rates (J , cm⁻³·s⁻¹) with varying ratios of [DSA]:[SA] at 238.15 K under different A concentrations ((a) 10^7 molecules·cm⁻³, (b) 10^9 molecules·cm⁻³, (c) 10^{11} molecules·cm⁻³).

4
5 **Fig. S19** Particle formation rates (J , cm⁻³·s⁻¹) with varying ratios of [DSA]:[SA] at 238.15 K
6 under different A concentrations ((a) 10^7 molecules·cm⁻³, (b) 10^9 molecules·cm⁻³, (c) 10^{11}
7 molecules·cm⁻³). [DSA] + [SA] = 10^4 - 10^8 molecules·cm⁻³

8 As shown in Fig. S19(a), at lower atmospheric concentration of A (10^7 molecules·cm⁻³), the
9 formation rate $J_{\text{DSA/SA}}$ at 1% substitution ([DSA]:[SA] = 1:99) was higher than that at
10 unsubstituted condition ([DSA]:[SA] = 0:100). Similarly, $J_{\text{DSA/SA}}$ at 10% substitution ([DSA]:[SA]
11 = 1:9) was higher than that at 1% substitution. Moreover, $J_{\text{DSA/SA}}$ at 50% substitution ([DSA]:[SA]
12 = 1:1) reach a maximum value (1.41×10^4 cm⁻³·s⁻¹), which is larger by 4-5 orders of magnitude
13 than the value at unsubstituted condition. These results at lower atmospheric concentration of A
14 show that the enhancement strength of DSA on the particle formation rate of SA-A-based clusters
15 increases with the increasing of the percentage of substitution.

16 At medium (10^9 molecules·cm⁻³) and higher (10^{11} molecules·cm⁻³) atmospheric concentration

1 of A, $J_{\text{DSA/SA}}$ at 50% substitution ($[\text{DSA}]:[\text{SA}] = 1:1$) reaches a maximum value. As compared
2 with $J_{\text{DSA/SA}}$ at unsubstituted condition, the value of $J_{\text{DSA/SA}}$ at 50% substitution ($[\text{DSA}]:[\text{SA}] = 1:1$)
3 enhanced by 10 and 11 orders of magnitude, respectively. However, as the percentage of
4 substitution ($> 50\%$) increases, the value of $J_{\text{DSA/SA}}$ at medium and higher [A] decreases. This may
5 be due to the fact that in the pure A-DNA nucleation system, large stable clusters $(\text{A})_3 \cdot (\text{DNA})_3$ can
6 only be formed by mutual collisions of $\text{A} \cdot \text{DNA}$ clusters. So, DNA has the same “acid” molecular
7 properties as SA in the SA-A-DNA ternary nucleation system. We predicted that DNA is a
8 relatively stronger nucleation precursor than SA.

9 Besides, it should be noted that the concentration of water in the troposphere is abundant, and
10 DNA is easily hydrolyzed to form 2 H_2SO_4 molecules. Based on this, the concentration of DNA
11 listed in Fig. S9 was overestimated. However, the extent and proportion of DNA hydrolysis
12 remains unclear, and the hydrolysis behavior of DNA needs to be further investigated in
13 subsequent studies. Therefore, the maximum concentration of DNA ($10^8 \text{ molecules} \cdot \text{cm}^{-3}$) was not
14 included in the effect of $\text{H}_2\text{S}_2\text{O}_7$, the product of the reaction between SO_3 and H_2SO_4 , on new
15 particle formation (NPF) in various environments by using the Atmospheric Cluster Dynamics
16 Code kinetic model and the QC calculation. In Lines 27-29 Page 7 to Lines 1-2 Page 7 of the
17 revised manuscript, the discussion of the DNA concentration has been added as “As the prediction
18 in Table S7, the concentration of DNA is set to 10^4 - $10^8 \text{ molecules} \cdot \text{cm}^{-3}$. However, DNA is easily
19 hydrolyzed with abundant water in the troposphere to form H_2SO_4 , the concentration of DNA
20 listed in Fig. S9 was overestimated. So, the maximum concentration of DNA ($10^8 \text{ molecules} \cdot \text{cm}^{-3}$)
21 was not included in the effect of $\text{H}_2\text{S}_2\text{O}_7$ on new particle formation (NPF) in various
22 environments.”

23

24 **Comment 10.**

25 **Line 162:** I do not believe the factors of 1/2 should be in this equation.

26 **Response:** Thanks for your valuable comments. The equation has been checked carefully and the
27 equation is correct. This is consistent with the previous literature (*Chemosphere*, **2020**, 245,
28 125554.; **2018**, 203, 26-33.; *Phys. Chem. Chem. Phys.*, **2018**, 20, 17406-17414.; **2023**, 25, 16745.;
29 *Atmos. Chem. Phys.*, **2012**, 12, 2345-2355.; **2022**, 22, 2639-2650.; **2021**, 21, 6221-6230.; **2022**,
30 22, 1951-1963.; *J. Chem. Phys.*, **2017**, 146, 184308.)

1 **Comment 11.**

2 **Line 168-169:** Please explicitly mention the boundary conditions and concentration ranges in the
3 text here instead of referring to the SI.

4 **Response:** Thank you for your valuable comments. According to your suggestion, boundary
5 conditions and concentration ranges have been added in Lines 20-29 Page 7 to Lines 1-4 Page 8 of
6 the revised manuscript, which has been organized as “**The boundary conditions in the ACDC**
7 **require that the smallest clusters outside of the simulated system should be very stable so that not**
8 **to evaporate back immediately (McGrath et al., 2012). Based on cluster volatilization rate (shown**
9 **in Table S10) and the formation Gibbs free energy of the clusters (shown in Table S8), the cluster**
10 **boundary conditions simulated in this study were set as (SA)₄·(A)₃, (SA)₄·(A)₄, SA·(A)₃·(DSA)₃,**
11 **(SA)₃·(A)₄·(DSA)₁ and (SA)₂·(A)₃·(DSA)₂. According to field observations, the concentration of**
12 **SA and A was respectively set in a range of 10⁶-10⁸ molecules·cm⁻³ and 10⁷-10¹¹ molecules·cm⁻³**
13 **(Almeida et al., 2013; Kuang et al., 2008; Bouo et al., 2011; Zhang et al., 2018). As the prediction**
14 **in Table S7, the concentration of DSA is set to 10⁴-10⁸ molecules·cm⁻³. However, DSA is easily**
15 **hydrolyzed with abundant water in the troposphere to form H₂SO₄, the concentration of DSA**
16 **listed in Fig. S9 was overestimated. So, the maximum concentration of DSA (10⁸ molecules·cm⁻³)**
17 **was not included in the effect of H₂S₂O₇ on new particle formation (NPF) in various environments.**
18 **Besides, the temperature was set to be 218.15-298.15 K, which span most regions of the**
19 **troposphere and the polluted atmospheric boundary layer.”**

20

21 **Comment 12.**

22 **Section 3.1:** I am missing some comments on why the titled reaction is of interest and how much
23 the competitive pathway of SO₃ + H₂O matters. Would SO₃ not react with water instead of H₂SO₄?
24 What are the branching ratios between these reaction pathways?

25 **Response:** Thanks for your valuable comments. The reason for our interest in SO₃ + H₂SO₄
26 reaction and the importance of the competition between the SO₃ + H₂SO₄ reaction and H₂O-
27 assisted hydrolysis of SO₃ have been discussed. The corresponding major revision has been made
28 as follows.

29 (a) Sulfur trioxide (SO₃) is a major air pollutant and can be considered as the most
30 important oxidation product of SO₂. As an active atmospheric species, SO₃ can lead to the

1 formations of acid rain and atmospheric aerosol and thus plays a well-documented role in regional
 2 climate and human health. In the atmosphere, the hydrolysis of SO₃ to product H₂SO₄ is the most
 3 major loss route of SO₃. Meanwhile, SO₃ can also react with NH₃, CH₃OH, HNO₃, HCl, organic
 4 acids (such as HCOOH), et al. the products of SO₃ with some important atmospheric species have
 5 been identified in promoting NPF process. However, H₂SO₄ plays a significant role as a major
 6 inorganic acidic air pollutant in the new particle formation and acid rain. The reaction of SO₃ with
 7 H₂SO₄ has not been investigated as far as we know. Thus, it is important to study the mechanism
 8 between SO₃ and H₂SO₄.

9 (b) To understand the competition between the SO₃ + H₂SO₄ reaction and H₂O-assisted
 10 hydrolysis of SO₃ in the Earth's atmosphere, the rate ratio ($v_{\text{DSA}}/v_{\text{SA}}$) between the SO₃ + H₂SO₄
 11 reaction and H₂O-assisted hydrolysis of SO₃ has been calculated and was expressed in Eq. (4).

$$12 \quad \frac{v_{\text{DSA}}}{v_{\text{SA}}} = \frac{k_{\text{DSA}} \times [\text{SO}_3] \times [\text{H}_2\text{SO}_4] + k_{\text{DSA_WM}_s} \times K_{\text{eq1}} \times [\text{SO}_3] \times [\text{H}_2\text{SO}_4] \times [\text{H}_2\text{O}]}{k_{\text{SA_WM}} \times K_{\text{eq2}} \times [\text{SO}_3] \times [\text{H}_2\text{O}] \times [\text{H}_2\text{O}]} \quad (4)$$

13 In Eq. (4), K_{eq1} and K_{eq2} were the equilibrium constant for the formation of H₂SO₄···H₂O and
 14 SO₃···H₂O complexes shown in Table S2, respectively; k_{DSA} , $k_{\text{DSA_WM}_s}$ and $k_{\text{SA_WM}}$ were
 15 respectively denoted the bimolecular rate coefficient for the H₂SO₄ + SO₃, H₂SO₄···H₂O + SO₃
 16 and SO₃···H₂O + H₂O reactions; [H₂O] and [H₂SO₄] were respectively represented the
 17 concentration of H₂O and H₂SO₄ taken from references (*J. Phys. Chem. A*, 2013, 117, 10381-
 18 10396.; *Environ. Sci. Technol.*, 2015, 49, 13112-13120.). The corresponding rate ratio have been
 19 listed in Table S7 (0 km altitude) and S8 (5-30 km altitude). As seen in Table S7, at 0 km altitude,
 20 the hydrolysis reaction of SO₃ with (H₂O)₂ is more favorable than the SO₃ + H₂SO₄ reaction as the
 21 [H₂O] (10¹⁶-10¹⁸ molecules·cm³) is much larger than that of [H₂SO₄] (10⁴-10⁸ molecules·cm³).
 22 Although the concentration of water molecules decreases with the increase of altitude in Table S8,
 23 the concentration of [H₂O] is still much greater than that of [H₂SO₄], resulting in the SO₃ + H₂SO₄
 24 reaction cannot compete with H₂O-assisted hydrolysis of SO₃ within the altitude range of 5-30 km.
 25 Moreover, the SO₃ + H₂SO₄ reaction is not also the major sink route of SO₃, even considering of
 26 high H₂SO₄ concentration at the end and outside the aircraft engine and flight. Based on this, the
 27 sentence of “The value of $v_{\text{DSA}}/v_{\text{SA}}$ was listed in Table S7 (0 km altitude) and S8 (5-30 km
 28 altitude). As seen in Table S7, at 0 km altitude, the hydrolysis reaction of SO₃ with (H₂O)₂ is more
 29 favorable than the SO₃ + H₂SO₄ reaction as the [H₂O] (10¹⁶-10¹⁸ molecules·cm³) is much larger

1 than that of [H₂SO₄] (10⁴-10⁸ molecules·cm⁻³). Although the concentration of water molecules
2 decreases with the increase of altitude in Table S8, the concentration of [H₂O] is still much greater
3 than that of [H₂SO₄], resulting in the SO₃ + H₂SO₄ reaction cannot compete with H₂O-assisted
4 hydrolysis of SO₃ within the altitude range of 5-30 km. Even considering of high H₂SO₄
5 concentration at the end and outside the aircraft engine and flight at 10 km (Curtius et al., 2002),
6 the SO₃ + H₂SO₄ reaction is not also the major sink route of SO₃.” has been added in Lines 24-29
7 Page 13 to Lines 1-4 Page 14 of the revised manuscript.

8 (c) It has been proposed that the concentration of sulfuric acid is even greater than that of
9 water vapor in the atmosphere of Venus (*Science*, 1990, 249, 1273.; *Planet. Space Sci.*, 2006, 54,
10 1352.; *Icarus*, 1994, 109, 58.; *Nat. Geosci.*, 2010, 3, 834.), which may lead to that the SO₃ +
11 H₂SO₄ reaction is probably favorable than the H₂O-assisted hydrolysis of SO₃ in the Venus’
12 atmosphere. To check whether the SO₃ + H₂SO₄ reaction is more favorable than H₂O-assisted
13 hydrolysis of SO₃ or not in the Venus’ atmosphere, the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ listed in Eq. 4 has
14 been calculated in Table 2. It can be seen from Table 2 that the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ is 3.24×10^8 -
15 5.23×10^{10} within the altitude range of 40-70 km in the Venus’ atmosphere, which indicates that
16 the SO₃ + H₂SO₄ reaction is significantly more favorable than the hydrolysis reaction of SO₃ +
17 (H₂O)₂ within the altitudes range of 40-70 km in the Venus’ atmosphere. Based on this, the
18 sentence of “Notably, as the concentration of sulfuric acid was even greater than that of water
19 vapor in the atmosphere of Venus, the SO₃ + SA reaction was probably favorable than the H₂O-
20 assisted hydrolysis of SO₃ in the Venus’ atmosphere. To check whether the SO₃ + H₂SO₄ reaction
21 was more favorable than H₂O-assisted hydrolysis of SO₃ or not in the Venus’ atmosphere, the rate
22 ratio of $v_{\text{DSA}}/v_{\text{SA}}$ listed in Eq. 4 has been calculated in Table 2. It can be seen from Table 2 that the
23 rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ was 3.24×10^8 - 5.23×10^{10} within the altitude range of 40-70 km in the
24 Venus’ atmosphere, which indicates that the SO₃ + H₂SO₄ reaction is significantly more favorable
25 than the hydrolysis reaction of SO₃ + (H₂O)₂ within the altitudes range of 40-70 km in the Venus’
26 atmosphere.” has been added in Lines 4-11 Page 14 of the revised manuscript.

27 Overall, it is important to study the mechanism between SO₃ and H₂SO₄ and the competition
28 between the SO₃ + H₂SO₄ reaction and H₂O-assisted hydrolysis. The SO₃ + SA reaction cannot
29 compete with H₂O-assisted hydrolysis of SO₃ within the altitude range of 0-30 km in the Earth’s
30 atmosphere, even considering of high H₂SO₄ concentration at the end and outside the aircraft

1 engine and flight. However, the $\text{SO}_3 + \text{SA}$ reaction is significantly more favorable than the
2 hydrolysis reaction of $\text{SO}_3 + (\text{H}_2\text{O})_2$ within the altitude range of 40-70 km in the Venus'
3 atmosphere.

4 **Comment 13.**

5 **Line 181:** *“Therefore, it can be said that the direct reaction between SO_3 and SA is more
6 favorable over H_2O -catalyzed hydrolysis of SO_3 energetically and kinetically.”*

7 I believe this conclusion should be based on the “reaction rates” and not the “reaction rate
8 constants”.

9 **Response:** Thank you for your valuable comments. We agree with the suggestion of the reviewer
10 that the conclusion should be based on the “reaction rates” and not the “reaction rate constants”.
11 So, in Lines 16-17 Page 8 of the revised manuscript, the sentence of “**Therefore, it can be said that
12 the direct reaction between SO_3 and SA is more favorable over H_2O -catalyzed hydrolysis of SO_3
13 energetically and kinetically.**” has been changed as “**Therefore, it can be said that the direct
14 reaction between SO_3 and SA occurs easily under atmospheric conditions.**”.

15

16 **Comment 14.1.**

17 **Section 3.2:** The first two sentences are contradicting each other. Is the mechanism lacking or
18 does it have high reactivity? I am also missing some information about how the system was setup.

19 **Response:** Thanks for your valuable comments. According to suggestion of reviewers, the first
20 two sentences in the section of “**3.2 Reactions at the Air-water interface**” has been re-organized.
21 The mechanism for the $\text{SO}_3 + \text{SA}$ reaction at the air-water interface was lacking and thus BOMD
22 simulations were used to evaluate the reaction mechanism of SO_3 with SA at the aqueous
23 interfaces. This reaction on water surface may occur in three ways: (i) SO_3 colliding with adsorbed
24 H_2SO_4 at the air-water interface; (ii) SO_3 colliding with adsorbed SO_3 at the aqueous interface; or
25 (iii) the $\text{SO}_3\text{-H}_2\text{SO}_4$ complex reacting at the aqueous interface. However, due to the high reactivity
26 both of SO_3 and H_2SO_4 with interfacial water, the lifetimes of SO_3 and H_2SO_4 on the water droplet
27 are extremely short (on the order of a few picoseconds). Thus, two possible models were mainly
28 considered for the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction on the water surface: (i) gaseous SO_3 colliding with
29 HSO_4^- at the air-water interface and (ii) the DSA (the gas-phase product of SO_3 and H_2SO_4)
30 dissociating on water droplet. Based on this, the sentence of “**Similar with the interfacial reaction**

1 of SO₃ with organic and inorganic acids (Cheng et al., 2023; Zhong et al., 2016), the reaction
2 between SO₃ and SA at the aqueous interface may occur in three ways: (i) SO₃ colliding with
3 adsorbed SA at the air-water interface; (ii) SO₃ colliding with adsorbed SO₃ at the aqueous
4 interface; or (iii) the SO₃-SA complex reacting at the aqueous interface. However, due to the high
5 reactivity both of SO₃ and SA at the air-water interface, the lifetimes of SO₃ (Zhong et al., 2019)
6 and SA (Fig. S2) (on the order of a few picoseconds) on the water droplet were extremely short
7 and can be formed SA⁻ ion quickly. Besides, as the calculated result above, SO₃···H₂SO₄ complex
8 can be generate DSA easily before it approaches the air-water interface.” has been deleted in Lines
9 17-25 Page 10 of the revised manuscript.

10
11 **Comment 14.2.**

12 Would the studied compounds (SO₃, H₂SO₄ and H₂S₂O₇) actually be at the interface or would they
13 be solvated in the water cluster?

14 **Response:** Thanks for your valuable comments. According to suggestion of reviewers, the time
15 evolution of the position (z coordinate) of SO₃, SA and DSA molecules is monitored so as to
16 observe whether these molecules stay at the air-water interface or in the water phase. The pie chart
17 with the occurrence percentages of SO₃, SA and DSA at the air-water interface and in water phase
18 has been displayed in Fig. S2. As seen in Fig. S2, the SO₃, SA and DSA molecules can stay at the
19 interface for 35.8%, 30.1% and 39.2% of the time in the 150 ns simulation (Fig. S2), respectively,
20 revealing that the existence of SO₃, SA and DSA at the air-water interface cannot be negligible.

21
22 **Comment 14.3.**

23 Is the reaction an artefact of not equilibrating the system before setting up the reaction?

24 **Response:** Thanks for your valuable comments. The droplet system with 191 water molecules has
25 been equilibrated before SO₃ and H₂SO₄ was added at the water surface. Specifically, a nearly
26 spherical droplet with 191 water molecules was firstly constructed by using the Packmol program
27 (*J. Comput. Chem.*, 2009, 30, 2157-2164.) with a tolerance of 2.0 Å, namely, all atoms from
28 different molecules will be at least 2.0 Å apart. Then, based on the resulting initial structure, the
29 GROMACS software (*J. Comput. Chem.*, 2005, 26, 1701-1718.) with the general AMBER force
30 field (GAFF) (*J. Comput. Chem.* 2004, 25, 1157-1174.) was used to simulate the droplet

1 equilibrium process with two steps. In the first step, a water slab of $35 \times 35 \times 35 \text{ \AA}^3$ containing
2 191 water molecules was built using periodic boundary conditions to avoid the effect of
3 neighboring replicas. In the second step, the water slab was fully equilibrated for 1 ns under NVT
4 ensemble (N, V and T represent the number of atoms, volume and temperature, respectively) to
5 reach equilibrium state. The water molecules were described by the TIP3P model. The isothermal-
6 isochoric (NVT) simulation was executed at 298 K for simulation system. The temperature was
7 kept constant by the V-rescale thermostat coupling algorithm. The coupling time constant is 0.1 ps.
8 Bond lengths were constrained by the LINCS algorithm. The cut-off distance of 1.2 nm was set
9 for van der Waals (vdW) interactions. The Particle Mesh Ewald (PME) summation method was
10 used to calculate the electrostatic interactions. During the whole simulation process, a time step of
11 2 fs was set and three-dimensional periodic boundary conditions were adopted. Next, to ensure the
12 stability of the system, the droplets were pre-optimized using BOMD at 300 K for 10 ps prior to
13 the simulation of the air-water interfacial reaction. Using the density functional theory (DFT)
14 method, the electronic exchange-correlation term was described by the Becke-Lee-Yang-Parr
15 (BLYP) functional. The Grimme's dispersion correction (D3) was applied to account for the weak
16 dispersion interaction. The double- ζ Gaussian (DZVP-MOLOPT) basis set and the Goedecker-
17 Teter-Hutter (GTH) norm-conserving pseudopotentials were adopted to treat the valence and the
18 core electrons, respectively. The planewave cutoff energy is set to 280 Ry, and that for the
19 Gaussian basis set is 40 Ry. And the SCF convergence criterion is $1.0\text{E-}5$ Hartree. All simulations
20 were performed in NVT ensemble with Nose-Hoover thermostat controlling the temperature.
21 Finally, the SO_3 and H_2SO_4 molecule was added at the water surface after the droplet system with
22 191 water molecules was fully equilibrated. The details of the equilibrium process for the droplet
23 system with 191 water molecules are shown in the *SI Appendix* Part 4. Meanwhile, the sentence of
24 "It is pointed out that the droplet system with 191 water molecules has been equilibrated before
25 SO_3 and H_2SO_4 was added at the water surface. The details of the equilibrium process for the
26 droplet system with 191 water molecules are shown in the *SI Appendix* Part 4." has been added in
27 Lines 22-25 Page 6 of revised manuscript.

28

29 **Comment 14.4.**

1 How many trajectories were carried out? Are adequate statistics ensured or can this be considered
2 a “rare event”.

3 **Response:** Thanks for your valuable comments. In the interfacial reactions of (i) gaseous SO₃
4 colliding with SA⁻ at the air-water interface and (ii) the DSA (the gas-phase product of SO₃ and
5 SA) dissociating on water droplet, sufficient statistical data are available in each reaction
6 mechanism. It is noted that 40 BOMD simulations were carried out in the air-water interface
7 reactions to eliminate the influence of the initial configuration on the simulation results of
8 interfacial reaction. So, the additional BOMD trajectories and snapshots for H₂O-induced the
9 formation of S₂O₇²⁻···H₃O⁺ ion pair, HSO₄⁻ mediated the formation of HSO₄⁻···H₃O⁺ ion pair and
10 the deprotonation of H₂S₂O₇ has been added in Fig. S4, Figs. S5-S6 and Fig. S7, respectively. Due
11 to the similarity of the same type of interfacial reaction mechanism, we do not list all the BOMD
12 trajectories and snapshots for H₂O-induced the formation of S₂O₇²⁻···H₃O⁺ ion pair, HSO₄⁻
13 mediated the formation of HSO₄⁻···H₃O⁺ ion pair and the deprotonation of H₂S₂O₇. However, in
14 Fig. S4-Fig. S7, at least 4 BOMD trajectories and snapshots were included in each Figure. Besides,
15 the sentence of “To eliminate the influence of the initial configuration on the simulation results of
16 interfacial reaction, 40 BOMD simulations for the air-water interface reactions were carried out.”
17 has been added in Lines 3-5 Page 7 of revised manuscript.

18

19 **Comment 14.5.**

20 What was the starting geometries? At the transition state?

21 **Response:** Thanks for your valuable comments. It is noted that the interfacial starting geometries
22 are not the transition state in the reaction of SO₃ with SA at the air-water interface. Specially, (a)
23 in H₂O-induced the formation of S₂O₇²⁻···H₃O⁺ ion pair from the reaction of SO₃ with HSO₄⁻ at the
24 air-water interface illustrated in Fig. 2 and Fig. S4, the starting geometries is the gaseous SO₃
25 collision with the adsorbed SA⁻, where the bond length between S1 atom of SO₃ and O1 atom of
26 HSO₄⁻ is set within the range of 3.0-4.0 Å; (b) In the hydration reaction mechanism of SO₃
27 mediated by HSO₄⁻ at the air water interface illustrated in Fig. 3, Fig. S5 and Fig. S6, the starting
28 geometries is the gaseous SO₃ collision with the adsorbed SA⁻, where the bond length between O4
29 atom of SO₃ and H3 atom of HSO₄⁻ is set within the range of 2.5-3.5 Å; (c) In the deprotonation of
30 H₂S₂O₇ at the air water interface illustrated in Fig. 4 and Fig. S7, the starting geometries is the

1 adsorbed DSA, where the distance between DSA and interfacial water molecule is set within the
2 range of 3.0-4.0 Å.

3

4 **Comment 14.6.**

5 Was the $\text{SO}_3+\text{H}_2\text{O}$ reaction observed in any of the trajectories? The reaction without SA should
6 also be tested.

7 **Response:** Thanks for your valuable comments. The interfacial hydration mechanism of SO_3
8 without H_2SO_4 has been reported previously by Lv et al. (*Atmos. Environ.*, 2020, 230, 117514.)
9 where the SO_3 can react rapidly with water molecules to form the ion pair of HSO_4^- and H_3O^+ or
10 H_2SO_4 within a few picoseconds. Three different reaction pathways, namely no loop-structure
11 formation, loop-structure formation with proton transfer in the loop and loop-structure formation
12 with proton transfer outside the loop, can be found from the results of BOMD simulations reported
13 by Lv et al. (*Atmos. Environ.*, 2020, 230, 117514.). So, the interfacial hydration mechanism of
14 SO_3 without H_2SO_4 has not been restudied here. However, the hydration reaction mechanism of
15 SO_3 at the air-water interface reported by Lv et al. (*Atmos. Environ.*, 2020, 230, 117514.) has
16 been compared with the interfacial hydration mechanism of SO_3 mediated by HSO_4^- reported in
17 the present work.

18 The interfacial hydration mechanism of SO_3 mediated by HSO_4^- were observed in the BOMD
19 simulations illustrated in Fig. 3, Fig. S5 and Fig. S6. Specifically, both direct (loop-structure
20 formation with proton transfer outside the loop, Fig. 3(a), Fig. S5 and Movie S2) and indirect (no
21 loop-structure formation, Fig. 3(b), Fig. S6 and Movie S3) forming mechanisms were observed in
22 HSO_4^- -mediated formation of $\text{HSO}_4^- \cdots \text{H}_3\text{O}^+$ ion pair. The loop-structure formation with proton
23 transfer in the loop was not observed in the BOMD simulations. The direct HSO_4^- -mediated
24 formation of $\text{HSO}_4^- \cdots \text{H}_3\text{O}^+$ ion pair was a loop structure mechanism, which was consistent with
25 gas phase hydrolysis of SO_3 assisted by acidic catalysts of HCOOH , HNO_3 , $\text{H}_2\text{C}_2\text{O}_4$ and H_2SO_4 in
26 the previous works (Long et al., 2012; Long et al., 2013a; Torrent-Sucarrat et al., 2012; Lv et al.,
27 2019) and the hydration reaction mechanism of SO_3 at the air water interface (*Atmos. Environ.*,
28 2020, 230, 117514.). During the direct formation route of $\text{HSO}_4^- \cdots \text{H}_3\text{O}^+$ ion pair, HSO_4^- played as
29 a spectator, while interfacial water molecules acted as both a reactant and a proton acceptor. The
30 indirect forming process of $\text{HSO}_4^- \cdots \text{H}_3\text{O}^+$ ion pair contained two steps: (i) SO_3 hydration along

1 with H₂SO₄ formation and (ii) H₂SO₄ deprotonation. During the whole indirect forming process of
2 HSO₄⁻···H₃O⁺ ion pair, HSO₄⁻ played as protons donor and acceptor, and water molecules acted as
3 hydration reactants and proton acceptors. The direct HSO₄⁻-mediated formation of HSO₄⁻···H₃O⁺
4 ion pair needs less time than the indirect forming process of HSO₄⁻···H₃O⁺ ion pair. This is
5 consistent with the interfacial reactions of CH₂OO + HNO₃ (*J. Am. Chem. Soc.*, 2018, 140, 14,
6 4913-4921.) and the hydration of SO₃ (*Atmos. Environ.*, 2020, 230, 117514.) where the direct
7 forming mechanism needs less time than indirect forming mechanism.

8 Based on the discussion above, the sentence of “As compared with the hydration reaction
9 mechanism of SO₃ at the air-water interface reported by Lv et al. (Lv and Sun, 2020), the loop-
10 structure formation with proton transfer in the loop was not observed in the direct mechanism of
11 SA⁻-mediated formation of SA⁻···H₃O⁺ ion pair. This is probably because SA⁻ ion is more difficult
12 to give the proton.” has been added in Lines 25-28 Page 12 of the revised manuscript. Meanwhile,
13 the sentence of “Compared with the direct mechanism of SA⁻-mediated formation of SA⁻···H₃O⁺
14 ion pair, the indirect forming process of HSO₄⁻···H₃O⁺ ion pair required more time. This was
15 consistent with the interfacial reactions of CH₂OO + HNO₃ (Kumar et al., 2018) and the hydration
16 of SO₃ (Lv and Sun, 2020) where the direct forming mechanism needed less time than indirect
17 forming mechanism.” has been added in Lines 15-19 Page 12 of the revised manuscript.

18

19 **Comment 15.**

20 **Section 3.3:** There is heavy referencing to the SI. Please also add the relevant data to the text. For
21 instance, at line 303, how can the H₂S₂O₇ formation reaction matter if SO₃ + (H₂O)₂ is the major
22 sink?

23 **Response:** Thank you for your valuable comments. According to your suggestion, the importance
24 of the SO₃ + H₂SO₄ reaction has been discussed and the competition between the SO₃ + H₂SO₄
25 reaction and H₂O-assisted hydrolysis of SO₃ in the atmospheres of Earth and Venus have been
26 discussed. Moreover, the relevant data listed in supporting information has been added to the
27 manuscript. The corresponding revision has been respectively made as follows.

28 (a) Sulfur trioxide (SO₃) is a major air pollutant and can be considered as the most
29 important oxidation product of SO₂. As an active atmospheric species, SO₃ can lead to the
30 formations of acid rain and atmospheric aerosol and thus plays a well-documented role in regional

1 climate and human health. In the atmosphere, the hydrolysis of SO₃ to product H₂SO₄ (SA) is the
 2 most major loss route of SO₃. As a complement to the loss of SO₃, ammonolysis reaction of SO₃
 3 in polluted areas of NH₃ can form H₂NSO₃H, which not only can be competitive with the
 4 formation of SA from the hydrolysis reaction of SO₃, but also can enhance the formation rates of
 5 sulfuric acid (SA)-dimethylamine (NH(CH₃)₂, DMA) clusters by about 2 times. Similarity, SO₃
 6 can also react with NH₃, CH₃OH, HNO₃, HCl, organic acids (such as HCOOH), and both
 7 processes can provide a mechanism for incorporating organic matter into aerosol particles. These
 8 reactions between SO₃ and trace atmosphere species above provide some complementary routes to
 9 the loss of SO₃ in locally polluted areas. However, the reaction mechanism between SO₃ and
 10 H₂SO₄ has yet to be fully understood. Previous studies have shown that the concentration of water
 11 vapor decreases significantly with increasing altitude (*J. Phys. Chem. A*, 2013, 117, 10381-10396.;
 12 *J. Am. Chem. Soc.*, 2021, 143, 8402-8413.), leading to longer atmospheric lifetimes of SO₃. The
 13 gas phase reaction of SO₃ with H₂SO₄ may contribute significantly to the loss of SO₃ in dry areas
 14 where [H₂SO₄] is relatively high (especially at lower temperatures) and at higher altitude. So, the
 15 reaction mechanism between SO₃ and H₂SO₄ has been studied here, and the competition between
 16 the SO₃ + H₂SO₄ reaction and H₂O-assisted hydrolysis of SO₃ have been discussed. Based on this,
 17 the sentence of “Previous studies have shown that the concentration of water vapor decreases
 18 significantly with increasing altitude, leading to longer atmospheric lifetimes of SO₃. The gas
 19 phase reaction of SO₃ with H₂SO₄ may contribute significantly to the loss of SO₃ in dry areas
 20 where [H₂SO₄] is relatively high (especially at lower temperatures) and at higher altitude. So, it is
 21 important to study the reaction mechanism of SO₃ with H₂SO₄ and its competition with H₂O-
 22 assisted hydrolysis of SO₃.” has been added in Lines 7-12 Page 3 of the revised manuscript.

23 (b) In the gas-phase, the main sink route of SO₃ is H₂O-assisted hydrolysis of SO₃. To
 24 understand the competition between the SO₃ + H₂SO₄ reaction and H₂O-assisted hydrolysis of SO₃
 25 in the Earth’s atmosphere, the rate ratio (v_{DSA}/v_{SA}) between the SO₃ + H₂SO₄ reaction and H₂O-
 26 assisted hydrolysis of SO₃ has been calculated and was expressed in Eq. (4).

$$27 \quad \frac{v_{\text{DSA}}}{v_{\text{SA}}} = \frac{k_{\text{DSA}} \times [\text{SO}_3] \times [\text{H}_2\text{SO}_4] + k_{\text{DSA_WM}_s} \times K_{\text{eq1}} \times [\text{SO}_3] \times [\text{H}_2\text{SO}_4] \times [\text{H}_2\text{O}]}{k_{\text{SA_WM}} \times K_{\text{eq2}} \times [\text{SO}_3] \times [\text{H}_2\text{O}] \times [\text{H}_2\text{O}]} \quad (4)$$

28 In Eq. (4), K_{eq1} and K_{eq2} were the equilibrium constant for the formation of H₂SO₄···H₂O and
 29 SO₃···H₂O complexes shown in Table S2, respectively; k_{DSA}, k_{DSA_WM_s} and k_{SA_WM} were

1 respectively denoted the bimolecular rate coefficient for the $\text{H}_2\text{SO}_4 + \text{SO}_3$, $\text{H}_2\text{SO}_4 \cdots \text{H}_2\text{O} + \text{SO}_3$
2 and $\text{SO}_3 \cdots \text{H}_2\text{O} + \text{H}_2\text{O}$ reactions; $[\text{H}_2\text{O}]$ and $[\text{H}_2\text{SO}_4]$ were respectively represented the
3 concentration of H_2O and H_2SO_4 taken from references (*J. Phys. Chem. A*, 2013, 117, 10381-
4 10396.; *Environ. Sci. Technol.*, 2015, 49, 13112-13120.). The corresponding rate ratio have been
5 listed in Table S7 (0 km altitude) and S8 (5-30 km altitude). As seen in Table S7, at 0 km altitude,
6 the hydrolysis reaction of SO_3 with $(\text{H}_2\text{O})_2$ is more favorable than the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction as the
7 $[\text{H}_2\text{O}]$ (10^{16} - 10^{18} molecules $\cdot\text{cm}^3$) is much larger than that of $[\text{H}_2\text{SO}_4]$ (10^4 - 10^8 molecules $\cdot\text{cm}^3$).
8 Although the concentration of water molecules decreases with the increase of altitude in Table S8,
9 the concentration of $[\text{H}_2\text{O}]$ is still much greater than that of $[\text{H}_2\text{SO}_4]$, resulting in the $\text{SO}_3 + \text{H}_2\text{SO}_4$
10 reaction cannot compete with H_2O -assisted hydrolysis of SO_3 within the altitude range of 5-30 km.
11 Moreover, the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction is not also the major sink route of SO_3 , even considering of
12 high H_2SO_4 concentration at the end and outside the aircraft engine and flight. Based on this, the
13 sentence of “The value of $v_{\text{DSA}}/v_{\text{SA}}$ was listed in Table S7 (0 km altitude) and Table S8 (5-30 km
14 altitude). As seen in Table S7, the hydrolysis reaction of SO_3 with $(\text{H}_2\text{O})_2$ is more favorable than
15 the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction at 0 km altitude as the $[\text{H}_2\text{O}]$ (10^{16} - 10^{18} molecules $\cdot\text{cm}^3$) is much larger
16 than that of $[\text{H}_2\text{SO}_4]$ (10^4 - 10^8 molecules $\cdot\text{cm}^3$). Although the concentration of water molecules
17 decreases with the increase of altitude in Table S8, the concentration of $[\text{H}_2\text{O}]$ is still much greater
18 than that of $[\text{H}_2\text{SO}_4]$, resulting in the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction cannot compete with H_2O -assisted
19 hydrolysis of SO_3 within the altitude range of 5-30 km. Even considering of high H_2SO_4
20 concentration at the end and outside the aircraft engine and flight at 10 km (Curtius et al., 2002),
21 the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction is not also the major sink route of SO_3 .” has been added in Lines 24-29
22 Page 13 to Lines 1-4 Page 14 of the revised manuscript.

23 (c) It has been proposed that the concentration of sulfuric acid is even greater than that of
24 water vapor in the atmosphere of Venus (*Science*, 1990, 249, 1273.; *Planet. Space Sci.*, 2006, 54,
25 1352.; *Icarus*, 1994, 109, 58.; *Nat. Geosci.*, 2010, 3, 834.), which may lead to that the $\text{SO}_3 +$
26 H_2SO_4 reaction is probably favorable than the H_2O -assisted hydrolysis of SO_3 in the Venus’
27 atmosphere. To check whether the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction is more favorable than H_2O -assisted
28 hydrolysis of SO_3 or not in the Venus’ atmosphere, the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ listed in Eq. 4 has
29 been calculated in Table 2. It can be seen from Table 2 that the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ is 3.24×10^8 -
30 5.23×10^{10} in the 40-70 km altitude range of Venus, which indicates that the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction

1 is significantly more favorable than the hydrolysis reaction of $\text{SO}_3 + (\text{H}_2\text{O})_2$ within the altitudes
2 range of 40-70 km in the Venus' atmosphere. Based on this, the sentence of “Notably, as the
3 concentration of sulfuric acid was even greater than that of water vapor in the atmosphere of
4 Venus, the $\text{SO}_3 + \text{SA}$ reaction was probably favorable than the H_2O -assisted hydrolysis of SO_3 in
5 the Venus' atmosphere. To check whether the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction was more favorable than
6 H_2O -assisted hydrolysis of SO_3 or not in the Venus' atmosphere, the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ listed in
7 Eq. 4 has been calculated in Table 2. It can be seen from Table 2 that the rate ratio of $v_{\text{DSA}}/v_{\text{SA}}$ was
8 3.24×10^8 - 5.23×10^{10} within the altitude range of 40-70 km in the Venus' atmosphere, which
9 indicates that the $\text{SO}_3 + \text{H}_2\text{SO}_4$ reaction is significantly more favorable than the hydrolysis
10 reaction of $\text{SO}_3 + (\text{H}_2\text{O})_2$ within the altitudes range of 40-70 km in the Venus' atmosphere.” has
11 been added in Lines 4-11 Page 14 of the revised manuscript.

12 Overall, it is important to study the reaction mechanism of SO_3 with H_2SO_4 and its
13 competition with H_2O -assisted hydrolysis of SO_3 . The $\text{SO}_3 + \text{SA}$ reaction cannot compete with
14 H_2O -assisted hydrolysis of SO_3 within the altitude range of 0-30 km in the Earth's atmosphere,
15 even considering of high H_2SO_4 concentration at the end and outside the aircraft engine and flight.
16 However, the $\text{SO}_3 + \text{SA}$ reaction is significantly more favorable than the hydrolysis reaction of
17 $\text{SO}_3 + (\text{H}_2\text{O})_2$ within the altitude range of 40-70 km in Venus' atmosphere.

18

19 **Comment 16.**

20 **Line 307-308:** The “stability analysis” should be added to the manuscript.

21 **Response:** Thank you for your valuable comments. According to your suggestion, the Gibbs free
22 energy ($\text{kcal}\cdot\text{mol}^{-1}$) diagram of $(\text{DSA})_x(\text{SA})_y(\text{A})_z$ ($z \leq x + y \leq 3$) clusters at 278.15K and 1 atm has
23 been added in Fig. 5. Meanwhile, evaporation rate coefficient (γ , s^{-1}) for $(\text{DSA})_x(\text{SA})_y(\text{A})_z$ ($z \leq x +$
24 $y \leq 3$) molecular clusters were calculated in Table S11-12. Based on this, the stability analysis
25 for $(\text{DSA})_x(\text{SA})_y(\text{A})_z$ ($z \leq x + y \leq 3$) molecular clusters has been added in Lines 12-27 Page 14 of
26 the revised manuscript, which has been organized as “From the multistep global minimum
27 sampling technique, for $(\text{DSA})_x(\text{SA})_y(\text{A})_z$ ($z \leq x + y \leq 3$) molecular clusters, 27 most stable
28 structures in the present system have been found (Fig. S11). To evaluate the thermodynamic
29 stability of these clusters, Gibbs formation free energies (ΔG) at 278.15 K and evaporation rate
30 coefficient (γ , s^{-1}) for $(\text{DSA})_x(\text{SA})_y(\text{A})_z$ ($z \leq x + y \leq 3$) molecular clusters were calculated in Fig.

1 5 and Table S11-12, respectively. As for dimers formed by SA, A and DSA, the ΔG of $(A)_1 \cdot$
2 $(DSA)_1$ was $-16.1 \text{ kcal}\cdot\text{mol}^{-1}$, which was lowest in all dimers followed by $(SA)_2$ ($-8.5 \text{ kcal}\cdot\text{mol}^{-1}$)
3 and then $(SA)_1 \cdot (A)_1$ ($-6.3 \text{ kcal}\cdot\text{mol}^{-1}$), meanwhile, the γ of $(A)_1 \cdot (DSA)_1$ ($1.17 \times 10^{-3} \text{ s}^{-1}$) was
4 lower than those of $(SA)_2$ ($3.81 \times 10^2 \text{ s}^{-1}$) and $(SA)_1 \cdot (A)_1$ ($4.19 \times 10^4 \text{ s}^{-1}$). Regarding for the SA-
5 A-DSA-based clusters, the values of ΔG and γ of SA-A-DSA-based clusters containing more DSA
6 molecules were relatively lower than the corresponding values of other SA-A-DSA-based clusters
7 with the same number of acid and base molecules. In the free-energy diagram for cluster
8 formation steps of the SA-A-DSA system (Fig. 5), thermodynamic barriers were weakened mainly
9 by the subsequential addition of A or DSA monomer. Also, the SA-A-DSA-based growth pathway
10 was thermodynamically favorable with decreasing ΔG . These results indicate that DSA not only
11 can promote the stability of SA-A-DSA-based clusters but also may synergistically participate in
12 the nucleation process.”

13
14 **Comment 17.**

15 **Line 312:** The application of the enhancement factor yields an incorrect picture of the importance
16 of $\text{H}_2\text{S}_2\text{O}_7$ for cluster formation. Sulfuric acid and ammonia form very weakly bound electrically
17 neutral clusters. Usually, ions are required to facilitate the process. Hence, large enhancement
18 factors (R) are an artefact of dividing with a very small number. Please mention the absolute
19 formation rates to ensure that the cluster formation rate is not zero.

20 **Response:** Thank you for your valuable comments. According to your suggestion, the formation
21 rate of SA-A-DSA-based system has been mainly discussed rather than the enhancement factor.
22 So, the influence of temperature and the precursor concentration on the formation rate ($J, \text{cm}^{-3}\cdot\text{s}^{-1}$)
23 has been discussed and reorganized in the revised manuscript. The corresponding revision has
24 been mainly made as follows.

25 (a) In Lines 28-30 Page 14 of the revised manuscript, the analysis of the influence of
26 temperature on formation rate has been discussed and organized as “**The potential enhancement**
27 **influence of DSA to the SA-A-based particle formation was shown in Fig. 6. The formation rate ($J,$**
28 **$\text{cm}^{-3}\cdot\text{s}^{-1}$) of SA-A-DSA-based system illustrated in Fig. 6 is negatively dependent on temperature,**
29 **demonstrating that the low temperature is a key factor to accelerate cluster formation.”.**

1 (b) In Lines 4-6 Page 15 of the revised manuscript, the analysis of the influence of [DSA]
2 has been discussed and organized as “In addition to temperature, the J of SA-A-DSA-based
3 system shown in Fig. 6 rise with the increase of [DSA]. More notably, the participation of DSA
4 can promote J to a higher level, indicating its enhancement on SA-A nucleation.”

5 (c) In Lines 6-13 Page 15 of the revised manuscript, the analysis of the influence of on both
6 [SA] and [A] has been discussed and organized as “Besides, there was significantly positive
7 dependence of the J of SA-A-DSA-based system on both [SA] and [A] in Fig. 7 (238.15 K) and
8 Fig. S15-Fig. S18 (218.15, 258.15, 278.15 and 298.15 K). This was because the higher
9 concentration of nucleation precursors could lead to higher J . Besides, Fig. S19 showed the
10 nucleation rate when the sum ($[SA] + [DSA]$) was kept constant. $J_{DSA/SA}$ at substituted condition
11 was higher than that at unsubstituted condition. These results indicated that DSA may can greatly
12 enhance the SA-A particle nucleation in heavy sulfur oxide polluted atmospheric boundary layer,
13 especially at an average flight altitude of 10 km with high [DSA].”

14
15 **Comment 18.**

16 **Line 316:** An R value of 1.0 will mean that there is no enhancement. Hence, I do not believe that
17 this can be stated. In addition, please add the numbers and explain how this conclusion of DSA
18 being a “better enhancer” is drawn.

19 **Response:** Thank you for your valuable comments. We agree with the suggestion of the reviewer
20 that it is incredible to use “enhancement factors” to explain the enhancing effect of the DSA.
21 According to your suggestion, the formation rate of SA-A-DSA-based system has been mainly
22 discussed rather than the enhancement factor. Meanwhile, the absolute formation rate has been
23 used to explain why DSA promotes the nucleation of SA-A particles. The corresponding revision
24 has been mainly made as follows.

25 (a) To evaluate the thermodynamic stability of these clusters, Gibbs formation free energies
26 (ΔG) at 278.15 K and evaporation rate coefficient (γ , s^{-1}) for $(DSA)_x(SA)_y(A)_z$ ($z \leq x + y \leq 3$)
27 molecular clusters were calculated in Fig. 5 and Table S11-12, respectively. As for dimers formed
28 by SA, A and DSA, the ΔG of $(A)_1 \cdot (DSA)_1$ is $-16.1 \text{ kcal} \cdot \text{mol}^{-1}$, which is lowest in all dimers
29 followed by $(SA)_2$ ($-8.5 \text{ kcal} \cdot \text{mol}^{-1}$) and then $(SA)_1 \cdot (A)_1$ ($-6.3 \text{ kcal} \cdot \text{mol}^{-1}$), meanwhile, the γ of
30 $(A)_1 \cdot (DSA)_1$ ($1.17 \times 10^{-3} \text{ s}^{-1}$) is lower than those of $(SA)_2$ ($3.81 \times 10^2 \text{ s}^{-1}$) and $(SA)_1 \cdot (A)_1$ ($4.19 \times$

1 10^4 s^{-1}). Regarding for the SA-A-DSA-based clusters, the values of ΔG and γ of SA-A-DSA-based
2 clusters containing more DSA molecules are relatively lower than the corresponding values of
3 other SA-A-DSA-based clusters with the same number of acid and base molecules. In the free-
4 energy diagram for cluster formation steps of the SA-A-DSA system (Fig. 5), thermodynamic
5 barriers are weakened mainly by the subsequential addition of A or DSA monomer. Moreover, the
6 J of SA-A-DSA-based system shown in Fig. 6 rise with the increase of [DSA]. More notably, the
7 participation of DSA can promote J to a higher level, indicating its enhancement on SA-A
8 nucleation.

9 (b) The influence of temperature and the precursor concentration on the formation rate (J ,
10 $\text{cm}^{-3}\cdot\text{s}^{-1}$) has been discussed in Lines 1-8 Page 15 of the revised manuscript. The detail
11 information is also provided in **Comment 17**.

12 (c) The contribution of the DSA participation pathway has been increased with increasing
13 temperature. Also, the contribution of the pathway with participation of DSA increases with
14 increasing [DSA], while the number of DSA molecules contained in clusters [(SA)₂·(A)₃·DSA,
15 SA·(A)₂·DSA, SA·(A)₃·(DSA)₂, and (A)₃·(DSA)₃] that can contribute to cluster growth has a
16 positive correlation with [DSA]. The corresponding revision has been made in Lines 20-24 Page
17 15 of the revised manuscript.

18

19 **Comment 19.**

20 **Line 325:** Please mention the absolute rates here to let the reader know if this enhancement of
21 many orders of magnitude is actually meaningful.

22 **Response:** Thank you for your valuable comments. According to your suggestion, the effects of
23 precursor concentration and temperature are mainly described by the formation rate, meanwhile,
24 the description of “enhancement factors” has been declined in the revised manuscript. The detail
25 information is also provided in **Comment 17**.

26

27 **Comment 20.**

28 **Line 336-339:** *“Hence, it can be forecasted that the participation of DSA in SA-A-based NPF can
29 likely enhance the number concentration of atmospheric particulates significantly in the polluted
30 atmospheric boundary layer (278.15 K) areas with relatively high [DSA] and [A].”*

1 I do not believe this claim is adequately supported by the data. Please report the absolute values to
2 support the conclusion.

3 **Response:** Thank you for your valuable comments. According to your suggestion, Meanwhile, the
4 contribution of the DSA participation pathway has been increased with increasing temperature.
5 Also, the contribution of the pathway with participation of DSA increases with increasing [DSA],
6 while the number of DSA molecules contained in clusters [(SA)₂·(A)₃·DSA, SA·(A)₂·DSA,
7 SA·(A)₃·(DSA)₂, and (A)₃·(DSA)₃] that can contribute to cluster growth has a positive correlation
8 with [DSA]. Based on this, the sentence of “Hence, it can be forecasted that the participation of
9 DSA in SA-A-based NPF can likely enhance the number concentration of atmospheric particulates
10 significantly in the polluted atmospheric boundary layer (278.15 K) areas with relatively high
11 [DSA] and [A].” has been changed as “These results suggested that DSA has the ability to act as a
12 potential contributor to SA-A-based NPF in the atmosphere at low *T*, low [SA], high [A] and high
13 [DSA], and the DSA participation pathway can be dominant in heavy sulfur oxide polluted
14 atmospheric boundary layer and in season of late autumn and early winter.”.

15

16 **Comment 21.**

17 **Line 367-368:** “Furthermore, the adsorption capacity of the S₂O₇²⁻, H₃O⁺ and SA⁻ to gaseous
18 precursors in the atmosphere was further investigated.”

19 How was this evaluated? From Table 2 it looks like only the binding free energies were calculated.
20 I guess the addition free energy of a given species should represent adsorption?

21 **Response:** Thanks for your valuable comments. Previous studies (*Angew. Chem. Int. Ed.*, 2019,
22 131, 8439-8443.) have used the interaction free energies to assess the adsorption capacity of
23 interfacial ions. So, we believe that it is reasonable to use the binding free energy to evaluate the
24 adsorption capacity of the S₂O₇²⁻, H₃O⁺ and SA⁻ to gaseous precursors in the atmosphere. Our
25 calculated the Gibbs free energies in Table 2 show that the interactions of S₂O₇²⁻···H₂SO₄, S₂O₇²⁻
26 ···HNO₃, S₂O₇²⁻···(COOH)₂, H₃O⁺···NH₃, H₃O⁺···H₂SO₄, SA⁻···H₂SO₄, SA⁻···(COOH)₂, and SA⁻
27 ···HNO₃ are stronger than those of H₂SO₄···NH₃ (major precursor of atmospheric aerosols) with
28 their binding free energies enhanced by 18.6-42.8 kcal·mol⁻¹. These results reveal that interfacial
29 S₂O₇²⁻, SA⁻ and H₃O⁺ can attract candidate species from the gas phase to the water surface.

30

1 **Comment 22.**

2 **Line 373-374:** I do not believe you can use a charged 2-3 molecular cluster in the gas-phase to
3 draw conclusions about the “acceleration of particle growth”

4 **Response:** Thanks for your valuable comments. We agree with the suggestion of the reviewer that
5 it is incorrect to use a charged 2-3 molecular cluster in the gas-phase to draw conclusions about
6 the “acceleration of particle growth”. In Line 15 Page 16, of the revised manuscript “and thus in
7 turn accelerates the growth of particle.” has been deleted; “enhancing potential of $S_2O_7^{2-}$ on SA-A
8 cluster” has been changed as “the nucleation potential of $S_2O_7^{2-}$ on SA-A cluster” and In Lines 23-
9 26 Page 16 of the revised manuscript “the Gibbs formation free energy ΔG of $(SA)_1(A)_1(S_2O_7^{2-})_1$
10 cluster is lower. Therefore, we predict that $S_2O_7^{2-}$ at the air-water interface has important
11 implication to the aerosol NPF in highly industrial polluted regions with high concentrations of
12 SO_3 .” has been changed as “the Gibbs formation free energy ΔG of $(SA)_1(A)_1(S_2O_7^{2-})_1$ cluster is
13 lower, showing $S_2O_7^{2-}$ ion at the air-water interface has stronger nucleation ability than X in the
14 gas phase. Therefore, we predict that $S_2O_7^{2-}$ at the air-water interface has stronger nucleation
15 potential.”. The $S_2O_7^{2-}$ ion at the air-water interface has stronger nucleation potential as the
16 following reasons. One reason is that the interactions of $S_2O_7^{2-}\cdots H_2SO_4$, $S_2O_7^{2-}\cdots HNO_3$, $S_2O_7^{2-}$
17 $\cdots (COOH)_2$, $H_3O^+\cdots NH_3$, $H_3O^+\cdots H_2SO_4$, $SA^-\cdots H_2SO_4$, $SA^-\cdots (COOH)_2$, and $SA^-\cdots HNO_3$ listed
18 in Table 2 are stronger than those of $H_2SO_4\cdots NH_3$ (major precursor of atmospheric aerosols).
19 These results reveal that interfacial $S_2O_7^{2-}$, SA^- and H_3O^+ can attract candidate species from the
20 gas phase to the water surface. The other reason is that as compared with $(SA)_1(A)_1(X)_1$ ($X =$
21 $HOOCCH_2COOH$, $HOCCOOSO_3H$, CH_3OSO_3H , $HOOCCH_2CH(NH_2)COOH$ and $HOCH_2COOH$)
22 clusters (Zhong et al., 2019; Zhang et al., 2018; Rong et al., 2020; Gao et al., 2023; Liu et al.,
23 2021a; Zhang et al., 2017), the number of hydrogen bonds in $(SA)_1(A)_1(S_2O_7^{2-})_1$ cluster presented
24 in Fig. S8 increased and the ring of the complex was enlarged. Meanwhile, comparing to
25 $(SA)_1(A)_1(X)_1$ ($X = HOOCCH_2COOH$, $HOCCOOSO_3H$, CH_3OSO_3H , $HOOCCH_2CH(NH_2)COOH$
26 and $HOCH_2COOH$) clusters (Table 2), the Gibbs formation free energy ΔG of $(SA)_1(A)_1(S_2O_7^{2-})_1$
27 cluster is lower, showing $S_2O_7^{2-}$ ion at the air-water interface has stronger nucleation ability than X
28 in the gas phase.

29

30 **Comment 23.**

1 **Line 380-382:** “It was demonstrated that $S_2O_7^{2-}$ has the highest potential to stabilize SA-A
2 clusters and promote SA-A nucleation in these clusters due to its acidity and structural factors
3 such as more intermolecular hydrogen bond binding sites”

4 I do not understand how this conclusion is drawn. What is the acidity of each of the compounds?

5 **Response:** Thanks for your valuable comments. The $S_2O_7^{2-}$ ion is formed by two deprotonations
6 of $H_2S_2O_7$, where the pK_{a1} and pK_{a2} of $H_2S_2O_7$ are -16.05 and -4.81 (*Dalton Trans.*, 2013, 42,
7 5566), respectively. This indicates that $S_2O_7^{2-}$ is a strong acid anion. Moreover, $S_2O_7^{2-}$ ion has
8 many exposed O atoms, which suggests that $S_2O_7^{2-}$ ion has more intermolecular hydrogen bond
9 binding sites. Besides, the pK_a for X (X = $HOOCCH_2COOH$, $HOCCOOSO_3H$, CH_3OSO_3H ,
10 $HOOCCH_2CH(NH_2)COOH$ and $HOCH_2COOH$) has been listed in the Table S8.

11 Table S8 The pK_a for $HOOCCH_2COOH$, $HOCCOOSO_3H$, CH_3OSO_3H ,
12 $HOOCCH_2CH(NH_2)COOH$ and $HOCH_2COOH$

Compound	pK_{a1}	pK_{a2}
$HOOCCH_2COOH$ ^a	2.85	5.89
$HOCCOOSO_3H$ ^b	4.73	-
CH_3OSO_3H ^c	10.2	-
$HOOCCH_2CH(NH_2)COOH$ ^d	1.99	3.90
$HOCH_2COOH$ ^e	3.83	-

13 ^a The value was taken from reference (*J. Am. Chem. Soc.*, 1994, 116, 10298-10299.)

14 ^{b and c} The values were calculated at the M06-2X/6-311++G(3df,2pd) level.

15 ^d The value was taken from reference (Data for Biochemical Research, second ed., Oxford University Press,
16 Oxford, 1969)

17 ^e The value was taken from reference (*Tissue Eng.*, 2007, 13, 2515-2523.)

19 **Comment 24.**

20 **Line 384:** An ion at a particle interface does not influence NPF.

21 **Response:** Thanks for your valuable comments. We agree with the suggestion of the reviewer that
22 an ion at air-water interface is not directly related to new particle formation. Although the reaction
23 of $H_2S_2O_7$ or H_2SO_4 formations at air-water interface is not directly related to new particle
24 formation. In Line 15 Page 14, of the revised manuscript “and thus in turn accelerates the growth
25 of particle.” has been deleted; “enhancing potential of $S_2O_7^{2-}$ on SA-A cluster” has been changed
26 as “the nucleation potential of $S_2O_7^{2-}$ on SA-A cluster” and In Lines 23-26 Page 16 of the revised
27 manuscript “the Gibbs formation free energy ΔG of $(SA)_1(A)_1(S_2O_7^{2-})_1$ cluster is lower. Therefore,

1 we predict that $S_2O_7^{2-}$ at the air-water interface has important implication to the aerosol NPF in
2 highly industrial polluted regions with high concentrations of SO_3 .” has been changed as “the
3 Gibbs formation free energy ΔG of $(SA)_1(A)_1(S_2O_7^{2-})_1$ cluster was lower, showing $S_2O_7^{2-}$ ion at
4 the air-water interface has stronger nucleation ability than X in the gas phase. Therefore, we
5 predict that $S_2O_7^{2-}$ at the air-water interface has stronger nucleation potential.”. The $S_2O_7^{2-}$ ion at
6 the air-water interface has stronger nucleation potential as the following reasons. One reason is
7 that the interactions of $S_2O_7^{2-}\cdots H_2SO_4$, $S_2O_7^{2-}\cdots HNO_3$, $S_2O_7^{2-}\cdots (COOH)_2$, $H_3O^+\cdots NH_3$,
8 $H_3O^+\cdots H_2SO_4$, $SA^-\cdots H_2SO_4$, $SA^-\cdots (COOH)_2$, and $SA^-\cdots HNO_3$ listed in Table 2 are stronger than
9 those of $H_2SO_4\cdots NH_3$ (major precursor of atmospheric aerosols). These results reveal that
10 interfacial $S_2O_7^{2-}$, SA^- and H_3O^+ can attract candidate species from the gas phase to the water
11 surface. The other reason is that as compared with $(SA)_1(A)_1(X)_1$ ($X = HOOCCH_2COOH$,
12 $HOCCOOSO_3H$, CH_3OSO_3H , $HOOCCH_2CH(NH_2)COOH$ and $HOCH_2COOH$) clusters (Zhong et
13 al., 2019; Zhang et al., 2018; Rong et al., 2020; Gao et al., 2023; Liu et al., 2021a; Zhang et al.,
14 2017), the number of hydrogen bonds in $(SA)_1(A)_1(S_2O_7^{2-})_1$ cluster presented in Fig. S8 increased
15 and the ring of the complex was enlarged. Meanwhile, comparing to $(SA)_1(A)_1(X)_1$ ($X =$
16 $HOOCCH_2COOH$, $HOCCOOSO_3H$, CH_3OSO_3H , $HOOCCH_2CH(NH_2)COOH$ and $HOCH_2COOH$)
17 clusters (Table 2), the Gibbs formation free energy ΔG of $(SA)_1(A)_1(S_2O_7^{2-})_1$ cluster is lower,
18 showing $S_2O_7^{2-}$ ion at the air-water interface has stronger nucleation ability than X in the gas phase.
