Abstract. Iodic acid (HIO₃) and iodous acid (HIO₂) have been identified to nucleate effectively by the Cosmics Leaving Outdoor Droplets (CLOUD) experiment at CERN, yet it may be hard to explain all HIO₃-induced nucleation. Given the complexity of marine atmosphere, other precursors may be involved. Methanesulfonic acid (MSA), as a widespread precursor over oceans, has been proven to play a vital role in facilitating nucleation. However, its kinetic impacts on the synergistic nucleation of iodine oxoacids remain unclear. Hence, we investigated the MSA-involved HIO₃-HIO₂ nucleation process at the molecular level using density functional theory (DFT) and Atmospheric Clusters Dynamic Code (ACDC). Our results show that MSA can form stable molecular clusters with HIO₃ and HIO₂ jointed via hydrogen bond, halogen bond, and electrostatic attraction after proton transfer to HIO₂. Thermodynamically, the MSA-involved clustering can occur nearly without free-energy barrier, following the HIO₂-MSA binary and HIO₃-HIO₂-MSA ternary pathway. Furthermore, our results show that considering MSA will significantly enhance the calculated rate of HIO₃-HIO₂-based cluster formation, with up to 10⁴-fold at cold marine regions containing rich MSA and scarce iodine, such as polar Ny-Ålesund and Marambio. Thus, the proposed more efficient HIO₃-HIO₂-MSA nucleation mechanism may provide theoretical evidence for explaining the frequent and intensive bursts of marine iodine particles.

1 Introduction

Marine aerosol, which is the primary natural aerosol (O'Dowd and Leeuw, 2007), has a significant impact on global climate, radiation balance, and even human health (Wang et al., 2010; Pöschl, 2005). New particle formation (NPF) is a primary source of marine aerosols, which proceeds via nucleation and subsequent growth (Lee et al., 2019; Zhang, 2010; Kulmala et al., 2013; Zhang et al., 2012). Moreover, the nucleation, forming critical clusters at 1-2 nm from gaseous precursors, is the pivotal step affecting NPF (Zhang, 2010; Kulmala et al., 2013). However, the chemicals involved in nucleation and the underlying mechanisms remain poorly understood, due to technological limitations in the molecular-level analysis. Additionally, the lack of comprehensive and long-term ocean observations, further hinders our knowledge of marine NPF.

Recent field studies suggest that marine NPF events are closely related to atmospheric iodine-bearing molecules emitted by algae (Yu et al., 2019; Baccarini et al., 2020; Beck et al., 2021). During the NPF events in coastal (e.g., Mace Head and Zhejiang) (Sipilä et al., 2016; Yu et al., 2019) and polar oceans (e.g., Arctic Ocean) (Baccarini et al., 2020), the nucleation processes are mainly driven by iodic acids (HIO_3). However, the self-nucleation of HIO_3 alone cannot fully explain the observed NPF rates (Rong et al., 2020). More recently, the Cosmics Leaving OUtdoor Droplets (CLOUD) experiment at CERN has found that iodous acid (HIO_2) plays a key role in stabilizing HIO_3 , enabling effective nucleation by the sequential addition of HIO_3 followed by HIO_2 (He et al., 2021). Further theoretical studies uncover that the stabilizing effect of HIO_2 on HIO_3 stems from its role as a base in clustering (Zhang et al., 2022b; Liu et al., 2023). Although the efficient nucleation of HIO_3 and HIO_2 is overall consistent with the CLOUD measurement (Zhang et al., 2022a), this mechanism does not account for all HIO_3 -induced nucleation in the authentic atmosphere (Ma et al., 2023). Thus, other essential precursors in the marine atmosphere might potentially affect HIO_3 - HIO_2 nucleation, but which and how remain largely unexamined.

Methanesulfonic acid (MSA), as a typical marine sulfur precursor, is widespread over oceans (Saltzman et al., 1983; Read et al., 2008; Chen et al., 2012; Yan et al., 2019) with considerable atmospheric concentrations ($10^5 - 10^8 \text{ molec. cm}^{-3}$) (Eisele and Tanner, 1993; Dal Maso et al., 2002; Chen et al., 2018; Yan et al., 2019). Moreover, MSA has been shown to initiate nucleation with vital atmospheric precursors, such as ammonia and amines, enhancing cluster formation (O'Dowd et al., 2002; Bork et al., 2014; Shen et al., 2019; Shen et al., 2020; Brean et al., 2021; Liu et al., 2022). Importantly, current evidence suggests that MSA can also form stable clusters with HIO_3 or HIO_2 individually, but none of the resulting binary nucleation can explain field measurements well (Ning et al., 2022; Wu et al., 2023). Despite the stabilizing effect of MSA on iodine oxoacids, it remains unknown whether MSA can synergistically nucleate with HIO_3 and HIO_2 , as well as the induced kinetic impacts on clustering. Furthermore, given the coexistence of MSA and HIO_3 in different marine regions (Quéléver et al., 2022; Beck et al., 2021), along with the consistent presence of HIO_3 and HIO_2 as homologous substances (Sipilä et al., 2016), the importance of the HIO_3 - HIO_2 -MSA nucleation mechanism may differ under distinct ambient conditions, but it remains unrevealed.

Herein, we have systematically investigated the HIO_3 - HIO_2 -based nucleation involved in MSA, including $(\text{HIO}_3)_x(\text{HIO}_2)_y(\text{MSA})_z$ ($1 \leq x + y + z \leq 5$, $0 \leq z \leq 3$) clusters, by combining quantum chemical (QC) approach and Atmospheric Clusters Dynamic Code (ACDC) (McGrath et al., 2012). To probe the nature of cluster formation, the wavefunction analysis was performed to investigate the intermolecular interactions. And the Gibbs free energies of cluster formation were calculated to evaluate cluster stability. Moreover, a series of ACDC simulations were executed to delve into the influence of MSA on nucleation rates and mechanisms under varying atmospheric conditions, such as precursor concentration and temperature.

2.1 Quantum Chemistry Calculations

To locate the low-lying isomers of $(\text{HIO}_3)_x(\text{HIO}_2)_y(\text{MSA})_z$ ($1 \leq x + y + z \leq 5$, $0 \leq z \leq 3$) clusters, the multi-step conformer search was adopted here (details in Supporting Information (SI)). The resulting stable clusters with the lowest energies were identified at $\omega\text{B97X-D}/6\text{-}311\text{++G}(3\text{df},3\text{pd})$ (for C, H, O, and S atoms) + aug-cc-pVTZ-PP with ECP28MDF (for I atom) level of theory (Francl et al., 1982; Peterson et al., 2003), and the corresponding Cartesian coordinates were collected in Table S9. In addition, the structures of pure-HIO₃, pure-HIO₂, pure-MSA, HIO₃-HIO₂, HIO₃-MSA, and HIO₂-MSA clusters in the present study were adopted from the previous studies (Rong et al., 2020; Zhang et al., 2022b; Liu et al., 2023; Ning et al., 2022; Wu et al., 2023). All density functional theory (DFT) calculations were carried out using the Gaussian 09 package (Frisch et al., 2009), where FineGrid and tight convergence were employed. The single-point energy was calculated at the RI-CC2/aug-cc-pVTZ (for C, H, and O atoms) + aug-cc-pV(T+d)Z (for S atom) + aug-cc-pVTZ-PP with ECP28MDF (for I atom) level of theory (Hättig and Weigend, 2000) by TURBOMOLE program (Ahlich et al., 1989), because of its success in fitting with the experiments (Lu et al., 2020; Kürten et al., 2018; Rong et al., 2020; Almeida et al., 2013). In the present study, the Gibbs formation free energy (ΔG_{ref} , kcal mol⁻¹) of the HIO₃-HIO₂-MSA clusters at the reference pressure (1 atm) was calculated as:

$$\Delta G_{\text{ref}} = \Delta E_{\text{RI-CC2}} + \Delta G_{\text{thermal}}^{\omega\text{B97X-D}}, \quad (1)$$

where $\Delta E_{\text{RI-CC2}}$ is the electronic contribution and $\Delta G_{\text{thermal}}^{\omega\text{B97X-D}}$ is the thermal contribution to free energy. The ΔG_{ref} at different temperatures ($T = 258 - 298$ K) were calculated using the Shermo 2.0 code (Lu and Chen, 2021) and collected in Table S1. Further given the effect of vapor pressures of the precursor, the ΔG_{ref} was converted to $\Delta G(P_1, P_2, \dots, P_n)$ (Vehkamäki, 2006) by the Eq. (2):

$$\Delta G(P_1, P_2, \dots, P_n) = \Delta G_{\text{ref}} - k_{\text{B}}T \sum_{i=1}^n N_i \ln\left(\frac{P_i}{P_{\text{ref}}}\right), \quad (2)$$

where n is the number of components within the cluster, k_{B} denotes the Boltzmann constant, T signifies the temperature, N_i refers to the number of molecules of type i in the number of components in the cluster, and P_i is the partial pressure of component i in the vapor phase.

2.2 Wavefunction Analysis

Wavefunction analysis was carried out using Multiwfn 3.7 (Lu and Chen, 2012) to investigate the binding nature within molecular clusters. The electrostatic potential (ESP) on the van der Waals (vdW) surface was calculated to identify active interaction sites. Specifically, the negative ESP region is electron-rich, while the positive ESP region is electron-deficient, potentially leading to mutual non-covalent interactions, such as hydrogen bonds (HBs) and halogen bonds (XBs). To further quantify the bond strength, the electron density $\rho(r)$, Laplacian electron density $\nabla^2\rho(r)$, and energy density $H(r)$ at bond critical points (BCPs) were calculated based on the atoms in molecules (AIM) theory (Lane et al., 2013).

90 2.3 Atmospheric Clusters Dynamic Simulations

To explore nucleation kinetic, the Atmospheric cluster dynamics code (ACDC) (McGrath et al., 2012) was adopted here to compute the cluster formation rates, steady-state concentrations, and formation pathways by explicit solution of the birth-death equations (Eq. (3)).

$$\frac{dC_i}{dt} = \frac{1}{2} \sum_{j < i} \beta_{j,(i-j)} C_j C_{(i-j)} + \sum_j \gamma_{(i+j) \rightarrow i} C_{i+j} - \sum_j \beta_{i,j} C_i C_j - \frac{1}{2} \sum_{j < i} \gamma_{i \rightarrow j} C_i + Q_i - S_i, \quad (3)$$

95 where the subscripts ($i, j, i-j$ and $i+j$) denote different clusters or monomers, C_i is the concentration of cluster i , $\beta_{i,j}$ and $\gamma_{(i+j) \rightarrow i}$ represent the cluster collision and evaporation rate coefficient, respectively. And Q_i and S_i denote the external source and sink terms, respectively. The $\beta_{i,j}$ is calculated as follows:

$$\beta_{i,j} = \left(\frac{3}{4\pi}\right)^{1/6} \left(\frac{6k_B T}{m_i} + \frac{6k_B T}{m_j}\right)^{1/2} (V_i^{1/3} + V_j^{1/3})^2, \quad (4)$$

100 where m_i and V_i represent the mass and volume of cluster i , respectively. And $V_i = 3/4 \times \pi \times (d_i/2)^3$, where the diameter d_i of cluster i is derived from the cluster volume V_i calculated by Multiwfn 3.7 (Lu and Chen, 2012). The $\gamma_{(i+j) \rightarrow i}$ is calculated by the Eq. (5):

$$\gamma_{(i+j) \rightarrow i} = \beta_{i,j} \frac{P_{\text{ref}}}{k_B T} \exp\left(\frac{\Delta G_{i+j} - \Delta G_i - \Delta G_j}{k_B T}\right), \quad (5)$$

where P_{ref} is the reference pressure at 1 atm, and ΔG is the formation free energy of the cluster.

105 In the performed ACDC simulations, we considered all possible collision and evaporation processes, including monomer-monomer, monomer-cluster and cluster-cluster collisions, as well as decomposition of parent clusters into monomers and clusters, or into two smaller clusters. Additionally, whether the clusters in the simulated system are stable depends on whether the rate of collision frequencies exceeds the total evaporation rate coefficients ($\beta C / \Sigma \gamma > 1$) (Table S4). The setting of the boundary conditions of ACDC simulations is summarized in Table S3. The uncertainty analysis was performed in this study (Table S8 and Figs. S15, S16 and S17), with details provided in Supporting Information (SI).

110 3 Results and Discussion

Here, conformational analysis was first carried out to study how MSA affects intermolecular interactions in the HIO₃-HIO₂-MSA clusters. And the thermodynamic analysis was employed to assess stability of the formed clusters. To gain insights into nucleation mechanisms, a series of ACDC simulations were executed under varying atmospheric conditions.

3.1 Cluster Conformational Analysis

115 Strong interactions among nucleation precursors are pivotal for forming stable clusters. To evaluate the binding potential of MSA with HIO₃ and HIO₂, we calculated the ESP-mapped molecular vdW surface to identify interaction sites. As illustrated

in Fig. 1, MSA has a positive ESP maximum (+63.95 kcal mol⁻¹) at the H atom of its -OH group, serving as a HB donor. The iodine atoms of HIO₃ and HIO₂ with positive ESP maximums (+51.90 and +45.26 kcal mol⁻¹), can act as XB donors. Additionally, the oxygen atoms in the S=O group (from MSA) and I=O group (from HIO₃ and HIO₂) with strong electronegativity can act as HB or XB acceptor sites, due to the lone pair electrons. Therefore, as shown in Fig. 1(d), MSA, HIO₃, and HIO₂ have the potential to form clusters via intermolecular HBs and XBs.

Figure 1. The ESP-mapped molecular vdW surface of (a) MSA, (b) HIO₂, (c) HIO₃ and (d) (HIO₃)₁(HIO₂)₁(MSA)₁. The golden and cyan dots represent the positions of maximums and minimums of ESP (unit: kcal mol⁻¹), respectively. The gray dashed arrows signify the site-to-site interaction tendencies.

As presented in Fig. 2, all the identified HIO₃-HIO₂-MSA clusters are structurally stabilized by the network of HBs (blue dashed lines) and XBs (red dashed lines). Within these clusters, the inward-facing oxygen atom and hydroxyl (-OH) group in MSA facilitates its being involved in forming more HBs and XBs, compared to the HIO₃-HIO₂ clusters (Fig. S1). Statistically, within HIO₃-HIO₂-MSA clusters, the percentage of XBs (61%) is higher than that of HBs (39%). Notably, during the HIO₃-HIO₂-MSA cluster formation, HIO₂ behaves like a base and is protonated by MSA instead of HIO₃, likely due to stronger acidity of MSA than HIO₃. After the MSA-driven proton transfer to HIO₂, the resulting electrostatic interactions between the formed ion pairs (CH₃SO₃⁻ - H₂IO₂⁺) further stabilize the clusters. Taken together, MSA can form clusters with HIO₃ and HIO₂ via HBs, XBs, and electrostatic attraction between ion pairs after proton transfer. Additionally, taking the (HIO₃)₁(HIO₂)₃(MSA)₁ cluster for example, there are still some potential remaining unoccupied binding sites as shown in Fig. S2. It suggests that the studied large-size clusters still have unoccupied HB and XB sites that can potentially facilitate the condensation of precursors in the atmosphere, enhancing further growth of marine aerosols.

To further quantify bond strength within HIO₃-HIO₂-MSA clusters, the topological analysis was performed based on the atoms in molecules (AIM) theory. The electron density $\rho(r)$, Laplacian electron density $\nabla^2\rho(r)$, and energy density $H(r)$ at the corresponding bond critical points (BCPs) in the studied HIO₃-HIO₂-MSA clusters were calculated and collected in Table S2. The $\rho(r)$ is generally positively associated with the bond strength. For the HIO₃-HIO₂-MSA clusters, $\rho(r)$ values at the BCPs of the HBs range from 0.0090 to 0.0869 a.u., exceeding the reported threshold of HB (0.002 – 0.040 a.u.) (Koch and Popelier, 1995; Grabowski, 2004). Moreover, the associated values of $\nabla^2\rho(r)$ at these BCPs range from 0.0310 to 0.1180 a.u., falling within the suggested range for HB (0.014 – 0.139 a.u.) (Koch and Popelier, 1995; Grabowski, 2004). Meanwhile, for O–I···O XBs, the $\rho(r)$ and $\nabla^2\rho(r)$ values within HIO₃-HIO₂-MSA clusters range from 0.0068 to 0.1999 a.u. and 0.0288 to 0.1744 a.u., respectively. Collectively, MSA can stabilize HIO₃-HIO₂ clusters via more relatively strong HBs and XBs, while also protonating HIO₂ to form ion pairs.

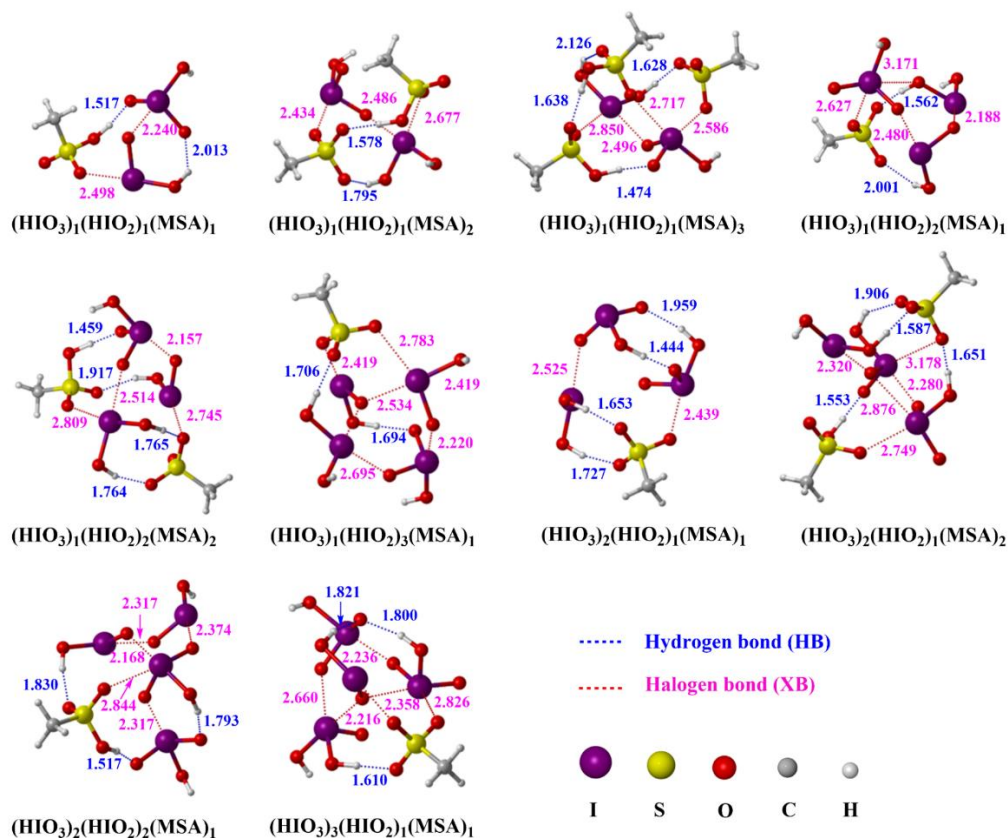

Figure 2. The most stable configurations of the HIO₃-HIO₂-MSA ternary clusters identified at the ω B97XD/6-311++G(3df, 3pd) (for C, H, O, and S atoms) + aug-cc-pVTZ-PP with ECP28MDF (for I atom) level of theory. The lengths of bonds are given in Å.

150 3.2 Cluster Formation Pathways and Free Energy Surface

To explore how MSA affects HIO₃-HIO₂-based nucleation kinetic, the ACDC simulations were employed to reveal the nucleation mechanism under varying atmospheric conditions. Based on the field measurement (Berresheim et al., 2002; Chen et al., 2018; Sipilä et al., 2016; Beck et al., 2021), the ranges of [MSA], [HIO₃], and [HIO₂] are set to be 10⁶ – 10⁸, 10⁶ – 10⁸ and 2.0 × 10⁴ – 2.0 × 10⁶ molec. cm⁻³, respectively, where [HIO₃]/[HIO₂] is a constant. Here, the condensation sink (CS) coefficient is set to be 2.0 × 10⁻³ s⁻¹ (Dal Maso et al., 2002) and the temperature (*T*) is 278 K. Under such conditions, the molecular-level nucleation pathways and the corresponding branching ratios are depicted in Fig. 3(a). The detailed branch ratio is also shown at 278 K (Fig. S3) and 268 K (Fig. S4). Furthermore, to comprehend how the growth occurs thermodynamically, we herein calculated the Gibbs free energies (ΔG , Eq. (2)) along the main clustering pathway at the conditions of *T* = 268 – 278 K, [HIO₃] = 1.0 × 10⁶, [HIO₂] = 2.0 × 10⁴, and [MSA] = 5.0 × 10⁶ molec. cm⁻³ (Fig. 3(b) and Fig. S5).

As shown in Fig. 3(a), the clustering pathways, at *T* = 278 K, CS = 2.0 × 10⁻³ s⁻¹, [HIO₃] = 1.0 × 10⁶, [HIO₂] = 2.0 × 10⁴, and [MSA] = 5.0 × 10⁶ molec. cm⁻³, can be categorized into two main types: i) MSA-involved pathways, including HIO₂-MSA and HIO₃-HIO₂-MSA nucleation; and ii) non-MSA pathways, primarily involving HIO₃-HIO₂ nucleation. For the HIO₂-MSA pathway, the initial formation of (HIO₂)₁(MSA)₁ heterodimer occurs without any energy barrier (Fig. 3(b)). And the subsequent cluster growth mainly proceeds via sequential addition of HIO₂ or MSA monomer, partly coupled with cluster collisions. Specifically, 63% of (HIO₂)₂(MSA)₂ results from (HIO₂)₂(MSA)₁ colliding with MSA monomer with an energy barrier of 1.00 kcal mol⁻¹, while 36% from a barrierless combination of two (HIO₂)₁(MSA)₁ cluster. At this point, kinetic drives growth by colliding (HIO₂)₂(MSA)₁ with MSA monomer, instead of following the lowest energy pathway. This is because the collision frequency of (HIO₂)₁(MSA)₁ and a HIO₂ monomer is relatively higher, stemming from the higher [HIO₂]. Then, the formed (HIO₂)₂(MSA)₂ further collides with a HIO₂ monomer, yielding the stable (HIO₂)₃(MSA)₂ cluster against evaporation. As to HIO₃-HIO₂-MSA nucleation, the formation of (HIO₃)₁(HIO₂)₃(MSA)₁ cluster arises from i) the collision of (HIO₂)₂(MSA)₁ with (HIO₃)₁(HIO₂)₁ (18%, energy barrier: 1.00 kcal mol⁻¹), and ii) (HIO₃)₁(HIO₂)₂ with (HIO₂)₁(MSA)₁ (62%, energy barrier: 0.17 kcal mol⁻¹), as well as iii) (HIO₃)₁(HIO₂)₃ binding with a MSA monomer (20%, energy barrier: 3.80 kcal mol⁻¹). In addition, for the non-MSA pathway marked by purple arrows, 76% of (HIO₃)₂(HIO₂)₂ cluster formation arises from the collision between two (HIO₃)₁(HIO₂)₁ cluster, which accords closely with the barrierless pathway shown in Fig. 3(b).

(a) Cluster formation pathway

Branch ratio of flux out ($T = 278 \text{ K}$, $CS = 2.0 \times 10^{-3} \text{ s}^{-1}$)

(b) Free energy surface of cluster formation

$T = 278 \text{ K}$, $[\text{HIO}_3] = 1.0 \times 10^6$, $[\text{HIO}_2] = 2.0 \times 10^4$, $[\text{MSA}] = 5.0 \times 10^6 \text{ molec. cm}^{-3}$

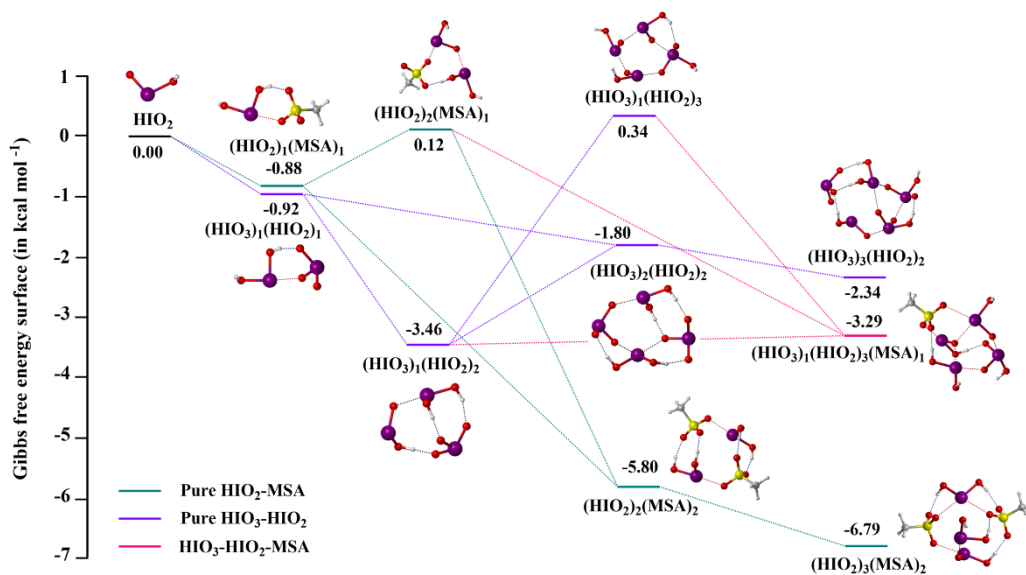

Figure 3. (a) Left: main cluster growth pathway of the HIO_3 - HIO_2 - MSA nucleation system at $T = 278\text{K}$, $CS = 2.0 \times 10^{-3} \text{ s}^{-1}$, $[\text{HIO}_3] = 1.0 \times 10^6$, $[\text{HIO}_2] = 2.0 \times 10^4$, and $[\text{MSA}] = 5.0 \times 10^6 \text{ molec. cm}^{-3}$. Right: branch ratio of flux out under varying $[\text{MSA}]$ ($10^6 - 10^8 \text{ molec. cm}^{-3}$) and $[\text{HIO}_3]$ ($10^6 - 10^8 \text{ molec. cm}^{-3}$). The yellow and purple arrows (or bar) denote MSA -involved and non- MSA flux out (or branch ratio), respectively. (b) The Gibbs free energies of cluster formation (ΔG , kcal mol^{-1}) based on the main clustering pathway in HIO_3 - HIO_2 - MSA nucleation system. $[\text{HIO}_3]/[\text{HIO}_2]$ is a constant.

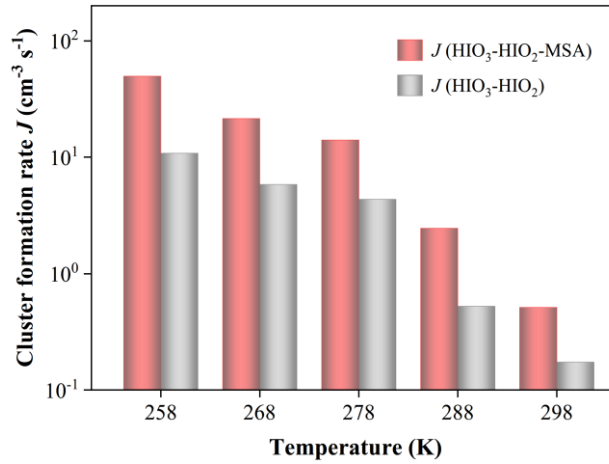

Overall, the MSA-involved pathways contribute to 74% of cluster formation, while the non-MSA path accounts for only 26%. Although the HIO₃-HIO₂-MSA growth pathway is less favorable than the HIO₃-HIO₂ and HIO₂-MSA pathways at $T =$
185 278 K, it can become barrierless at a lower temperature of 268 K (Fig. S5). This result may be explained by the fact that the lower temperature results in a decrease in the evaporation rates of the HIO₃-HIO₂-MSA clusters. The detailed cluster evaporation paths and corresponding γ at 268 K and 278 K are collected in Table S5 and Table S6. Generally, stable clusters have lower evaporation rates. According to the calculated cluster evaporation rates ($\Sigma\gamma$, s⁻¹) at 278 K (Table S7), more than
190 40% of the clusters have $\Sigma\gamma$ less than 10⁻³ s⁻¹, indicating relatively high stability ($\beta C/\Sigma\gamma > 1$). Among these resulting stable clusters (see Fig. S6), the majority (85%) contain HIO₂. Moreover, the concentration of these stable clusters increases gradually with time, even reaching a maximum of 10⁴ molec. cm⁻³ (Fig. S6). Of these stable clusters, initial (HIO₃)₁(HIO₂)₁, (HIO₂)₂, and (MSA)₁(HIO₂)₁ dimer form rapidly, and at $t = \sim 1$ s, heterotrimers (HIO₃)₁(HIO₂)₂ and (MSA)₁(HIO₂)₂ begin to form, after which, the larger-sized clusters also form. These time-dependent evidence suggests that MSA is involved in the whole clustering process, from the initial formation of smaller clusters to the large-sized nucleated clusters that potentially further
195 grow. Taken together, these findings highlight the direct and significant involvement of MSA in HIO₃-HIO₂ nucleation, facilitating cluster formation.

As presented in the right of Fig. 3(a), the contribution of different clustering pathways to the flux out varies with precursor concentrations. With increasing [MSA] from 10⁶ to 10⁸ molec. cm⁻³, the contribution of MSA-involved pathways rises from 1% to 99% during nucleation. And at the median [MSA] of 10⁷ molec. cm⁻³, the MSA-involved pathway contributes 86%,
200 whereas the non-MSA pathway accounts for just 14%. In contrast, the ratio of MSA-involved pathways decreases (from 86% to 0%) with increasing concentrations of iodine oxoacids. At higher [HIO₃] of 10⁸ molec. cm⁻³, the HIO₃-HIO₂ pathway dominates nucleation. Predictably, the kinetic impact of MSA on HIO₃-HIO₂ nucleation is more pronounced in marine regions with richer MSA away from iodine sources.

3.3 Enhancement on Cluster Formation Rates

205 Guided by the clustering pathway analysis, MSA has shown its potential to participate in the HIO₃-HIO₂-based nucleation, but its detailed impacts on cluster formation rates (J , cm⁻³ s⁻¹) remain uncertain. Herein, the influence of MSA on J under different atmospheric conditions is systematically analyzed below.

Figure 4 presents the simulated J of HIO₃-HIO₂-MSA (red bar) and HIO₃-HIO₂ system (grey bar) against the varying temperatures ($T = 258 - 298$ K) at $CS = 2.0 \times 10^{-3}$ s⁻¹, $[HIO_3] = 1.0 \times 10^7$, $[HIO_2] = 2.0 \times 10^5$, and $[MSA] = 1.0 \times 10^7$ molec.
210 cm⁻³. Clearly, $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ is consistently higher than $J(\text{HIO}_3\text{-HIO}_2)$, highlighting the enhancement of MSA on HIO₃-HIO₂-based clustering under common atmospheric temperatures. Specifically, both $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ and $J(\text{HIO}_3\text{-HIO}_2)$ are negatively dependent on T , due to reduced cluster evaporation caused by low T . As a result, MSA could promote nucleation with higher J , especially at the colder regions, such as polar oceans.

215 **Figure 4.** Simulated cluster formation rates J ($\text{cm}^{-3} \text{s}^{-1}$) against varying atmospheric temperatures: $T = 258 - 298 \text{ K}$, $\text{CS} = 2.0 \times 10^{-3} \text{ s}^{-1}$,
 220 $[\text{HIO}_3] = 1.0 \times 10^7$, $[\text{HIO}_2] = 2.0 \times 10^5$, and $[\text{MSA}] = 1.0 \times 10^7 \text{ molec. cm}^{-3}$.

It's worth noting that apart from atmospheric temperature, precursor concentrations might also vary regionally or seasonally, which can further affect nucleation. So, to comprehensively reveal the effect of MSA, here we defined and calculated MSA-driven enhancement factor R (Eq. (6)) under varying concentrations of MSA, HIO_3 , and HIO_2 (i.e., $[\text{MSA}]$,
 220 $[\text{HIO}_3]$, and $[\text{HIO}_2]$, unit: molec. cm^{-3}).

$$R = \frac{J(\text{HIO}_3\text{-HIO}_2\text{-MSA})}{J(\text{HIO}_3\text{-HIO}_2)} = \frac{J([\text{HIO}_3] = x, [\text{HIO}_2] = y, [\text{MSA}] = z)}{J([\text{HIO}_3] = x, [\text{HIO}_2] = y)}, \quad (6)$$

where $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ and $J(\text{HIO}_3\text{-HIO}_2)$ represent the cluster formation rate of $\text{HIO}_3\text{-HIO}_2\text{-MSA}$ and $\text{HIO}_3\text{-HIO}_2$ system, respectively. x , y and z are the adopted $[\text{HIO}_3]$, $[\text{HIO}_2]$, and $[\text{MSA}]$, respectively.

225 **Figure 5.** Enhancement strength R of MSA on cluster formation rates at varying precursor concentrations: $[\text{HIO}_3] = 10^6 - 10^8$, $[\text{HIO}_2] = 2.0 \times 10^4 - 2.0 \times 10^6 \text{ molec. cm}^{-3}$, (a) $[\text{MSA}] = 1.0 \times 10^6 \text{ molec. cm}^{-3}$, (b) $[\text{MSA}] = 1.0 \times 10^7 \text{ molec. cm}^{-3}$, and (c) $[\text{MSA}] = 1.0 \times 10^8 \text{ molec. cm}^{-3}$, $T = 278 \text{ K}$, $\text{CS} = 2.0 \times 10^{-3} \text{ s}^{-1}$.

As seen from Fig. 5, with [MSA] ranging from 10^6 to 10^8 molec. cm^{-3} (Fig. 5(a) – (c)), the maximum R increases from 5 to 10^4 -fold, which is primarily due to MSA-mediated synergistic nucleation with HIO_3 and HIO_2 (recalling Sect. 3.2). Even at a median [MSA] of 1.0×10^7 molec. cm^{-3} , the resulting R can reach approximately 10^2 -fold. In contrast, R is decayed at conditions of higher $[\text{HIO}_3]$ and $[\text{HIO}_2]$. Furthermore, at the conditions with lower $[\text{HIO}_3]/[\text{HIO}_2]$, where R is higher, the contribution of MSA nucleating with HIO_2 increases due to the relative scarcity of HIO_3 . Conversely, R decreases at higher $[\text{HIO}_3]/[\text{HIO}_2]$, i.e., the impacts of MSA decreases. That is, the enhancing effect of MSA on J is limited in near-iodine source regions. Naturally, in regions with sparser iodine, the promoting effect of MSA is significant. However, the atmospheric $[\text{HIO}_3]$ ranges widely from 10^6 to 10^8 molec. cm^{-3} . When $[\text{HIO}_3]$ is comparable or higher than [MSA], the HIO_3 - HIO_2 pathway contributes more, and the R of MSA decreases with the rising $[\text{HIO}_3]$. It is worth noting that when $[\text{HIO}_3]$ is comparable to [MSA], the R of MSA is greater than 2, as the contribution of MSA to clustering includes not only the direct formation of HIO_3 - HIO_2 -MSA clusters (~20%), but also its ‘catalysis’ role in facilitating formation of initial HIO_3 - HIO_2 clusters (Fig. S7). To sum up, MSA can promote nucleation, particularly in marine regions characterized by lower T , lower $[\text{HIO}_3]$ and $[\text{HIO}_2]$. In addition, we also considered the conditions in relatively polluted ($\text{CS} = 1.0 \times 10^{-2} \text{ s}^{-1}$) and clean ($\text{CS} = 1.0 \times 10^{-4} \text{ s}^{-1}$) environments and found that, similar to the environment with a CS value of $2.0 \times 10^{-3} \text{ s}^{-1}$, MSA exhibits significant promoting effect on iodine particle formation (Figs. S8 – S11). Furthermore, the effect of HIO_2 addition on the whole nucleation system was considered, as it is not only the rate-limiting step for cluster formation, leading to the significant increasement of the $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ compared to $J(\text{HIO}_3\text{-MSA})$ (Fig. S12), but also thermodynamically favorable due to HIO_3 - HIO_2 -MSA path is almost barrierless ($1.24 \text{ kcal mol}^{-1}$) compared to HIO_3 -MSA pathway (Fig. S13).

3.4 Comparison with Field Observations

To further assess the atmospheric implication of the proposed HIO_3 - HIO_2 -MSA nucleation, we herein simulated J in Fig. 6 based on the ambient conditions of the typical polar regions (e.g., Ny-Ålesund and Marambio) and the mid-latitude marine regions (e.g., Mace Head and Réunion). Subsequently, we compared these simulation results with observed nucleation rates and the definition of cluster formation rate was detailed in Supporting Information (SI). As shown in Fig. 6(a), the $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ simulated at $T = 268 \text{ K}$, $\text{CS} = 4.0 \times 10^{-4} \text{ s}^{-1}$, $[\text{HIO}_3] = 10^5 - 10^6$, $[\text{HIO}_2] = 2.0 \times 10^3 - 2.0 \times 10^4$, and $[\text{MSA}] = 10^6 - 10^8$ molec. cm^{-3} was compared with field observations in coastal Ny-Ålesund (Beck et al., 2021; He et al., 2021). Both $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ and $J(\text{HIO}_3\text{-HIO}_2)$ increase with the rising $[\text{HIO}_3]$ and $[\text{HIO}_2]$. Importantly, the addition of MSA effectively promotes J to a higher level (orange area), aligning with most field measurements ($1.2 \times 10^{-3} - 1.2 \times 10^{-1} \text{ cm}^{-3} \text{ s}^{-1}$, gray lines) (Beck et al., 2021). Even when [MSA] is as low as 1.0×10^6 molec. cm^{-3} (the orange line below), the $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ can be one order of magnitude higher than the observed J of $1.2 \times 10^{-3} \text{ cm}^{-3} \text{ s}^{-1}$ (the gray line below). Moreover, the simulated J in Fig. 6(b) was obtained at the conditions of coastal Marambio, Antarctic: $T = 273 \text{ K}$, $\text{CS} = 1.0 \times 10^{-4} \text{ s}^{-1}$, $[\text{HIO}_3] = 10^5 - 10^6$, $[\text{HIO}_2] = 2.0 \times 10^3 - 2.0 \times 10^4$, and $[\text{MSA}] = 10^6 - 10^7$ molec. cm^{-3} (Quéléver et al., 2022; He et al., 2021). Compared to $J(\text{HIO}_3\text{-HIO}_2)$, the MSA-enhanced $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ is overall higher, better fitting with the field observations

260 $(1.2 \times 10^{-1} - 2.4 \times 10^1 \text{ cm}^{-3} \text{ s}^{-1})$ (Quéléver et al., 2022). These findings imply that MSA potentially plays a vital role in cold polar oceanic regions, particularly with higher [MSA] during NPF events.

In addition, the influence of $\text{HIO}_3\text{-HIO}_2\text{-MSA}$ nucleation over the relatively warmer mid-latitude marine areas, such as Mace Head and Réunion, was investigated here (Fig. S14). We found that $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$ is slightly higher than $J(\text{HIO}_3\text{-HIO}_2)$, especially at regions with high concentrations of iodine oxoacids (e.g., Mace Head), showing a relatively limited
 265 enhancement of MSA on nucleation. Based on the simulated $J(\text{HIO}_3\text{-HIO}_2)$ ($\sim 1.2 \times 10^4 \text{ cm}^{-3} \text{ s}^{-1}$), iodine nucleation can pretty much explain the NPF events of Mace Head (Fig. S14(a)), which provides potential theoretical evidence for explaining the previous findings (Sipilä et al., 2016).

Overall, at the mid-latitude oceans, especially near iodine sources like Mace Head, MSA may have limited enhancement on nucleation. In this case, the clustering process is dominated by abundant iodine oxoacids. While in the colder polar regions,
 270 particularly with higher [MSA] like Marambio, MSA indeed significantly facilitates $\text{HIO}_3\text{-HIO}_2$ nucleation, suggesting a vital role in polar NPF.

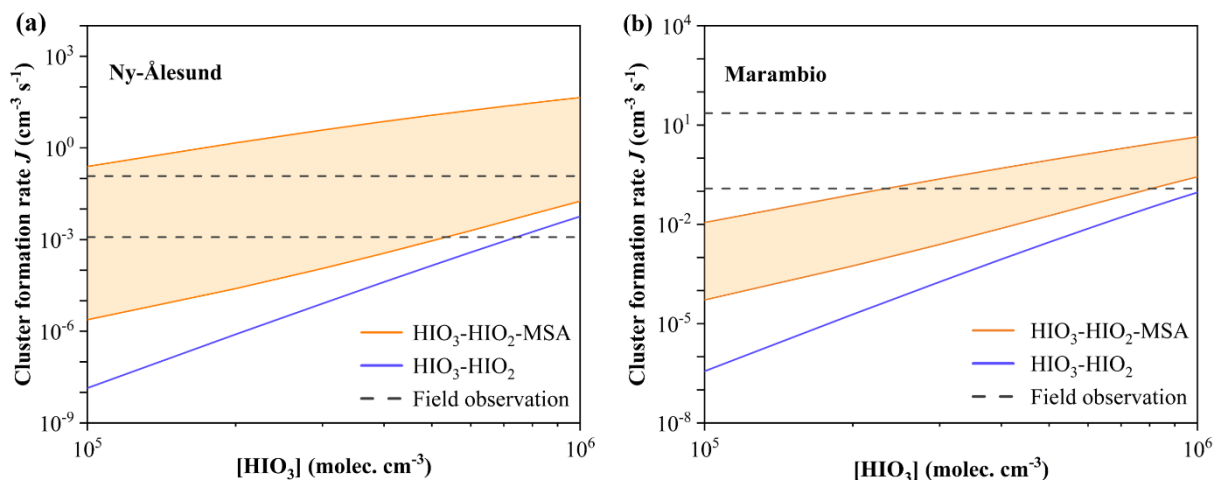

Figure 6. Comparison with the simulated cluster formation rates (J , $\text{cm}^{-3} \text{ s}^{-1}$) and field observations at the ambient conditions of (a) Ny-Ålesund ($T = 268 \text{ K}$, $\text{CS} = 4.0 \times 10^{-4} \text{ s}^{-1}$, $[\text{HIO}_3] = 10^5 - 10^6$, $[\text{HIO}_2] = 2.0 \times 10^3 - 2.0 \times 10^4$, and $[\text{MSA}] = 10^6 - 10^8 \text{ molec. cm}^{-3}$), (b)
 275 Marambio ($T = 273 \text{ K}$, $\text{CS} = 1.0 \times 10^{-4} \text{ s}^{-1}$, $[\text{HIO}_3] = 10^5 - 10^6$, $[\text{HIO}_2] = 2.0 \times 10^3 - 2.0 \times 10^4$, and $[\text{MSA}] = 10^6 - 10^7 \text{ molec. cm}^{-3}$). The orange area, blue line and gray line represent $J(\text{HIO}_3\text{-HIO}_2\text{-MSA})$, $J(\text{HIO}_3\text{-HIO}_2)$, and $J(\text{Field observation})$, respectively. $[\text{HIO}_3]/[\text{HIO}_2]$ is a constant.

4 Conclusion

The present study systematically investigates the $\text{HIO}_3\text{-HIO}_2$ -based nucleation process enhanced by MSA at the molecular
 280 level by QC calculations and ACDC simulations. The results indicate that MSA can stabilize $\text{HIO}_3\text{-HIO}_2$ -based clusters by

building the intricate networks with more HBs and XBs. During clustering, MSA replaces HIO₃ in protonating HIO₂ to form ion pairs, resulting in relatively strong electrostatic attractions. In addition, thermodynamic analyses suggest that MSA-involved clustering is nearly barrierless. Compared to the HIO₃-HIO₂ system reported previously, the MSA-involved synergistic nucleation with HIO₃ and HIO₂ proceeds more efficiently, through two additional clustering pathways: i) HIO₂-MSA binary and ii) HIO₃-HIO₂-MSA ternary pathway. Moreover, the resulting enhancement of MSA on nucleation is more substantial at colder regions, especially with richer MSA, but weaker in the environments near iodine source. Further comparison with field observations indicates that the HIO₃-HIO₂-MSA synergistic nucleation plays a limited role in mid-latitude ocean regions, particularly in regions with abundant iodine (e.g., Mace Head), but a potential role in colder polar regions (e.g., Ny-Ålesund and Marambio).

285
290 This study highlights the essential enhancing role of MSA in iodine oxoacids nucleation, and the HIO₃-HIO₂-MSA synergistic nucleation may help to explain the observation of abundant iodine particles during marine NPF events. Given the complex oceanic atmosphere, other potential nucleation precursors beyond MSA, such as sulfuric acid and amines, may also affect the HIO₃-HIO₂ nucleation process and further contribute to the formation of marine iodine particles, which deserves future investigations.
