16 **Abstract**

17 This study implements the least-squares inversion method for solving the exhumation history from
18 thermochronologic age-elevation relationship (AER) based on the linear equation among
19 exhumation rate, age and total exhumation from the closure depth to the Earth surface. Modelling
20 experiments suggest significant and systematic influence of initial geothermal model, the *a priori*
21 exhumation rate and the time interval length on the *a posterior* exhumation history. Lessons
22 learned from the experiments include that (i) the modern geothermal gradient can be used for
23 constraining the initial geothermal model, (ii) a relatively higher *a priori* exhumation rate would
24 lead to systematically lower *a posteriori* exhumation, and *vice versa*, (iii) the variance of the *a*
25 *priori* exhumation rate controls the variation of the inverted exhumation history, (iv) the choice of
26 time interval length should be optimized for resolving the potential temporal changes in
27 exhumation. Putting together these findings, we implemented a new stepwise inverse modeling
28 method for optimizing the model parameters by comparing the observed and predicted
29 thermochronologic data and modern geothermal gradient to mitigate the model dependencies on
30 the initial parameters. Finally, method demonstration was performed using four synthetic datasets
31 and three natural examples of different exhumation rates and histories, It is shown that the inverted
32 rock exhumation histories from the synthetic datasets match the whole picture of the “truth”,
33 although the temporal changes in the magnitude exhumation are underestimated. Modelling of the
34 datasets from natural samples produce geologically reasonable exhumation histories. The code and
35 data used in this work is available in GitHub (https://github.com/yuntao-github/A2E_app).

52 **1. Introduction**

53 Quantifying rock exhumation from the Earth interior to the surface is important information for
54 better understanding many geological problems, ranging from orogenic growth (e.g., Zeitler et al.,
55 2001; Whipp Jr. et al., 2007) and decay (e.g., House et al., 2001; Hu et al., 2006), to resource and
56 hydrocarbon evaluation and exploration (e.g., Armstrong, 2005; McInnes et al., 2005), as well as
57 the underpinning endogenic and exogenic processes and their interactions (e.g., Burbank et al.,
58 2003; Fox et al., 2015; Tian et al., 2015). Various experimental and modeling methods have been
59 invented for estimating the rock exhumation at different crustal levels (e.g., Braun, 2003; Reiners
60 and Brandon, 2006; Anderson et al., 2008; Braun et al., 2012; Fox et al., 2014).

61 One type of the methods for estimating the rock exhumation in the middle and upper crust
62 relies on thermochronologic cooling ages acquired from by noble gas and fission-track dating of a
63 series of accessory minerals, such as Ar-Ar, fission-track and (U-Th)/He analyses (Ault et al., 2019
64 and references therein). Based on the closure temperature theory (Dodson, 1973), assuming
65 monotonic cooling, a thermochronologic age records the time duration that a rock cooled through
66 the corresponding closure temperature, which is a function of the kinematics describing fission-
67 track annealing and noble gas diffusion, and rock cooling rate (Dodson, 1973). If the depth of the
68 closure temperature isotherm can be estimated from the crustal temperature field, a time-averaged
69 exhumation rate can be obtained from the cooling age.

70 Based on the thermochronologic methods and thermo-exhumation modelling, many
71 analytical and numerical tools have been implemented for inverting the exhumation and/or the
72 associated cooling history from thermochronologic data. These tools have different functions, such
73 as inverting temperature history (Laslett et al., 1987; Ketcham, 2005; Gallagher, 2012),
74 determining time-averaged exhumation rates (Brandon et al., 1998; Ehlers, 2005; Willett and

Deleted: (Farley, 2002; Reiners, 2005)

Deleted: cooling

83 Brandon, 2013; Glotzbach et al., 2015; Van Der Beek and Schildgen, 2023), spatiotemporal
84 changes in exhumation (Sutherland et al., 2009; Herman et al., 2013; Fox et al., 2014; Willett et
85 al., 2020), and evolution of exhumation in two or three dimensions given a tectonic framework
86 (Batt and Brandon, 2002; Braun, 2003; Van Der Beek et al., 2010; Valla et al., 2011; Braun et al.,
87 2012).

88 Convincing estimate of exhumation history for a region requires both a proper sampling
89 strategy for thermochronologic data and a robust modeling approach for exhumation inversion,
90 especially when the rock exhumation and its spatiotemporal changes are tectonically controlled
91 (Ehlers and Farley, 2003; Schildgen et al., 2018). A routine and efficient sampling strategy
92 acquires thermochronologic ages from an elevation transect over a significant relief and a relatively
93 confined spatial distance. Plotting the age versus elevation, i.e., the age-elevation relationship
94 (AER), and analyzing the slope changes of the plot can provide first-order understanding of the
95 exhumation history (Fitzgerald et al., 1986). Because both the subsurface geothermal field and
96 closure temperature of thermochronometers are functions of the thermal advection and cooling
97 during rock exhumation (e.g., Dodson, 1973; Brandon et al., 1998), as well as the long-wavelength
98 topography (Braun, 2002; Ehlers and Farley, 2003; Glotzbach et al., 2015), Estimating reliable
99 exhumation rates requires to account for temporal variations of the thermal field caused by changes
100 in the thermal and kinematic boundary conditions.

101 Fox et al. (2014) reported a linear inversion modeling method that solves exhumation
102 history from AER, given a combination of *a priori* exhumation rates and assumed geothermal
103 parameters. However, as shown in that study, the inverted exhumation history depends highly on
104 these *a priori* values and geothermal assumptions. Building on that study, we here provide a

Deleted: Other suggestions for model setup are also provided in this work.

112 2. Linear inversion method

113 Our inversion of exhumation from thermochronologic data followed the linear inversion
114 approach of Fox et al. (2014). Rock Exhumation from the closure depth of a thermochronometer,
115 z_c , to the Earth's surface can be described as an integral of the exhumation (\dot{e}) from the cooling
116 age (τ) to the present (Brandon et al., 1998; Fox et al., 2014). For a set of correlated bedrock
117 samples with a shared history of exhumation rates (\dot{e}), their thermochronologic ages (\mathbf{A}) and the
118 corresponding closure depths (\mathbf{z}_c) can be expressed by the following equation.

$$119 \int_0^{\tau} \dot{e} dt = z_c \Rightarrow \mathbf{Ae} = \mathbf{z}_c, \quad (1)$$

120 where \mathbf{A} is a model matrix, with n rows (the total number of samples) and m columns (the total
121 number of time intervals). Each row of the matrix is a discretization of a sample age, which is
122 composed of a number of time lengths (Δt) followed by an age residual (R_i) and a number of zeros.
123 The \dot{e} is a m -length vector of exhumation rates, and the \mathbf{z}_c is n -length vector of closure depths.

124 This linear equation can be solved using the Least-Squares Regression approach assuming
125 the Gaussian uncertainties and *a priori* mean exhumation rate (\dot{e}_{pr}) and associated variance (σ_{pr})
126 (Tarantola, 2005; Fox et al., 2014). Such an approach requires a $m \times m$ -sized parameter covariance
127 matrix, \mathbf{C} , and a $n \times n$ -sized data covariance matrix, \mathbf{C}_e , which includes the uncertainties on the
128 closure depths. These two matrices can be constructed as equations 2 and 3, respectively.

$$129 C_{ij} = \begin{cases} \sigma_{pr}^2, & \text{if } i = j \\ 0, & \text{if } i \neq j \end{cases} \quad (2)$$

$$130 (C_e)_{ij} = \begin{cases} e_{pr} \epsilon_i, & \text{if } i = j \\ 0, & \text{if } i \neq j \end{cases}, \quad (3)$$

134 where \hat{e}_{pr} and σ_{pr} are the *a priori* exhumation and the associated variance, and the ε_i is analytical
 135 uncertainty of the age data. The construction of the data covariance matrix assumes the age data
 136 are uncorrelated. Worth noting is that previous studies used different constructions of the data
 137 covariance, changing from using the analytical age uncertainties (Fox et al., 2014; Fox et al., 2015)
 138 to constant values (Jiao et al., 2017; Stalder et al., 2020).

139 Given the above model parameters, the equation 1 has a maximum likelihood solution for
 140 the exhumation rate vector:

$$141 \quad \mathbf{e}_{po} = \mathbf{e}_{pr} + \mathbf{CA}^T (\mathbf{ACA}^T + \mathbf{C}_\epsilon)^{-1} (\mathbf{z}_c - \mathbf{Ae}_{pr}), \quad (4)$$

142 where \hat{e}_{pr} is a n-length vector of \hat{e}_{pr} , \mathbf{z}_c is the n-length vector of closure depths calculated using a
 143 combination of exhumation and geothermal model parameters (see section 3). The \hat{e}_{po} is the
 144 posteriori maximum likelihood estimate of the exhumation rate, with a covariance matrix, \mathbf{C}_{po} ,
 145 which provides an estimate of the uncertainties on the model parameters (equation 5).

$$146 \quad \mathbf{C}_{po} = \mathbf{C} - \mathbf{CA}^T (\mathbf{ACA}^T + \mathbf{C}_\epsilon)^{-1} \mathbf{AC} \quad (5)$$

147 The method also provides a model resolution matrix, \mathbf{R} , which gives a measure on how
 148 well the model estimates correspond to the true values:

$$149 \quad \mathbf{R} = \mathbf{CA}^T (\mathbf{ACA}^T + \mathbf{C}_\epsilon)^{-1} \mathbf{A}. \quad (6)$$

151 3. Closure depth and topographic correction

152 Inversion of the exhumation using the equation 1 requires accurate estimates of the closure
 153 depths of the thermochronologic ages (\mathbf{z}_c), i.e., the depth of the closure temperatures (Fig. 1). The
 154 latter can be determined by modelling the temperature of the crust using a 1D thermal-kinematic
 155 model, which accounts for heat conduction, advection and production, (Turcotte and Schubert,
 156 2002):

Deleted: These depths can be determined from the underground temperature model, which can be simplified as and calculated by the following 1D thermal conduction and convection equation

$$\frac{\partial T_m}{\partial t} = \kappa \frac{\partial^2 T_m}{\partial z^2} + e \frac{\partial T_m}{\partial z} + A_b, \quad (7)$$

where A_b is the heat production (in °C/Myr). This function can be numerically solved using a Crank–Nicolson time integration with a set of initial and boundary conditions, such as an initial geothermal gradient (G0) at the start time of the model and surface temperature (T_s) (Turcotte and Schubert, 2002; Fox et al., 2014).

The closure temperature (T_c) of a thermochronometer is a function of cooling rate (\dot{T}) at the closure time and kinetic parameters of Helium and Argon diffusion and fission-track annealing in mineral phases (Dodson, 1973):

$$T = \frac{\Omega R T_c^2}{E_a} \exp\left(\frac{-E_a}{R T_c}\right), \quad (8)$$

where Ω and E_a are the diffusion frequency factor normalized by the mineral size and geometry, and activation energy, respectively. Parameter R is the gas law constant. See reviews by Reiners and Brandon (2006) for the Ω and E_a parameter values for different thermochronometers.

The cooling rate (\dot{T}) can be computed from the derivative of transient geotherms, $T_m(t,z)$ that can be computed using equation 7 (Fox et al., 2014):

$$T = \frac{\partial T_m}{\partial t} + e \frac{\partial T_m}{\partial z}, \quad (9)$$

where e is unknown exhumation that can be computed through the equation 1.

Combining the equations 7-9, the closure depth of a thermochronological system ($z_{c,m}$) can be numerically computed. This depth also needs a topographic correction, because of the topographic perturbation, p , on the isotherms (Braun, 2002; Ehlers and Farley, 2003; Fox et al., 2014; Glotzbach et al., 2015). Such a perturbation can be determined by the following equation (Mancktelow and Grasemann, 1997; Fox et al., 2014):

$$p(\lambda) = \left(\frac{\gamma_0 - \gamma_a}{\gamma_{z_m}}\right) \exp\left(-z_m \left(\frac{e}{2\kappa} + \sqrt{\left(\frac{e}{2\kappa}\right)^2 + (2\pi\kappa)^2}\right) h(\lambda)\right), \quad (10)$$

183 where γ_a is the atmospheric lapse rate, γ_0 and γ_{z_m} are the thermal gradients at the model surface and
184 at the depth z_m . The $h(\lambda)$ is a cosine function expression of the model surface topography, which
185 can be determined using the discrete Fast Fourier Transform at the frequency domain. Here we use
186 the SRTM30 data for computing the topography of regions of interests.

187 Finally, the closure depth of the z_c is corrected by the topographic perturbation (e.g.,
188 Brandon et al., 1998):

$$(z_c)_i = (z_{c,m})_i - p_i + h_i, \quad (11)$$

189 where $z_{c,m}$ is the closure depth calculated using the 1D geothermal model, p and h are the
190 topographic perturbation and elevation difference with respect to the mean elevation at the sample
191 site (Fig. 1), and the i denotes the i -th age.

192
193 As shown by the equations 7, 8 and 9, the closure depth is a non-linear function of rock
194 cooling and exhumation. Therefore, the problem of interest is non-linear, which can be addressed
195 by iterative numerical modelling methods. In this work, the solution of exhumation is
196 approximated by coupling and iterating the linear inversion and closure depth modeling. As shown
197 in Tarantola (2005) and Fox et al. (2014), the algorithm converges in a few iterations and produces
198 stable outputs.

199

200 4. Model evaluation

201 Quantitative model assessment relies on a misfit value, i.e., the difference between
202 observed and predicted ages weighted by the observed analytical uncertainty;

$$\Phi_\tau = \sqrt{\frac{1}{N} \sum_{i=1}^N \left(\frac{\tau_{prd,i} - \tau_{obs,i}}{\varepsilon_i} \right)^2}, \quad (12)$$

203
204 where $\tau_{obs,i}$ and $\tau_{prd,i}$ are the observed and predicted i -th age calculated from the exhumation history,
205 and ε_i is the uncertainty of the observed i -th age. Following Fox et al. (2014), both the *a priori* and

Deleted: the

Deleted: fitness of the predicted ages to the observed, using the following misfit function

209 *a posteriori* misfits, $\Phi_{\tau, pr}$ and $\Phi_{\tau, po}$, are determined for the models. The difference between these
210 two misfit values provides a measure of the model improvements. A smaller posteriori misfit value
211 indicates an improved **model result**, and *vice versa*.

Deleted: data fitness

212 To evaluate the geothermal parameters, we also determined the misfit value of the
213 predicted to the observed modern geothermal gradient value using the following equation:

$$\Phi_{\gamma} = \sqrt{\left(\frac{\gamma_{prd} - \gamma_{obs}}{\varepsilon_{\gamma}}\right)^2}, \quad (13)$$

214 where γ_{prd} and γ_{obs} are the predicted and observed geothermal gradients, and ε_{γ} is the uncertainty
215 of the observed value. Because the depth-temperature curves are slightly non-linear, the predicted
216 geothermal gradient (γ_{prd}) is calculated as a mean value for the upper 1 km of the model. Similar
217 as the assessment of age data, we also determined the *a priori* and *a posteriori* misfits, $\Phi_{\gamma, pr}$ and
218 $\Phi_{\gamma, po}$ values for assessing the geothermal parameters.

220

221 5. The reference inverse model

222 Following Willett and Brandon (2013) and Fox et al. (2014), here we use the published
223 AFT data acquired from Denali Massif (Fitzgerald et al., 1995) for method demonstration (Fig.
224 2a). A break-in-slope is shown by the AER at ~7-6 Ma, indicating a coeval change in slope, i.e.,
225 the apparent exhumation rate (Fitzgerald et al., 1995), increasing from 0.17 ± 0.04 km/Myr to 1.2
226 ± 0.6 km/Myr (Fig. 2b). AER regression of young dates from the lower part of the transect
227 (between 4.3-2.0 km) also predicts a closure depth that is the intercept at -3.3 ± 3.4 km (Fig. 2b).
228 However, using the present geothermal gradient (38.9 °C/km) (Fox et al., 2014) and a nominal
229 closure temperature of AFT method (110 °C) (Reiners and Brandon, 2006) and a -12 °C surface
230 temperature (Fox et al., 2014), the closure depth is predicted as ~3.1 km beneath the mean elevation

Deleted: change

233 (~4 km), which is equivalent to an elevation of ~0.9 km. This closure depth is significantly higher
234 than the intercept (-3.3 ± 3.4 km). Such a difference indicates the AER slope of the lower part
235 overestimates the exhumation rates since ~7-6 Ma.

236 Following the protocol outlined in Fox et al. (2014), the reference inverse model uses the
237 following parameters, a start time at 25 Ma, a time interval (Δt) of 2.5 Myr, a 4020 m mean
238 elevation, a -12 °C surface temperature, *a priori* exhumation rate of 0.5 ± 0.15 km/Myr, a 24 °C/km
239 initial geothermal gradient, a 38.9 °C/km present geothermal gradient, a model block with a
240 thickness of 80 km, and a 30 km²/Myr thermal diffusivity.

241 The exhumation history output of the reference model is shown in Fig. 3. The inversion
242 results reveal an more than two-fold increase of exhumation rate to a value of ~0.6 km/Myr at 7.5
243 Ma (Fig. 3b), consistent with the development of the break-in-slope in the AER. The model also
244 shows a gradual decrease of exhumation rate from *a priori* exhumation rate (0.5 km/Myr) to 0.3
245 km/Myr from 25 Ma to 7.5 Ma. The invariant exhumation during the starting stage resulted from
246 the fact that all ages are younger than 17.5 Ma, and thus the data have no resolution for the time
247 span. These results are similar to those of Fox et al. (2014). The posteriori misfit for the age is
248 1.88, significantly smaller than that of the priori model (4.51), suggesting the improvement by the
249 inverse modeling (Fig. 3b). Such a model also provides reasonable fit to the modern temperature
250 field, as shown by the small misfit (0.39) in the geothermal gradient (Fig. 3b).

251 The resolution of the inverted exhumation history can be assessed by the resolution matrix
252 **R** (equation 6). Imaging of the matrix shows the model provides no resolution for the time period
253 before 17.5 Ma (Fig. 3c), consistent with the fact that the oldest input age is younger than $16.1 \pm$
254 0.9 Ma. For the time span between 15 and 5 Ma, the model resolution is high, as shown by the
255 diagonal elements of the matrix, with the highest resolution at 7.5-5 Ma span, including eight age

268 date points (Fig. 3c). The most recent two phases of exhumation (5-0_Ma) are less resolved, as
269 shown by the nearly equal resolution values for the two phases, i.e., the latest four pixels of the
270 matrix (Fig. 3c). ~~This is because no input ages fall into this time span, when the~~ modeled
271 exhumation results are time-averaged values. The slight decrease in the last stage reflects changes
272 in geothermal gradient.

Deleted: , as no ages fall into this time interval

Deleted: The

Deleted: for the time interval

Deleted: thus

273 For assessing the correlation among model parameters, the calculated covariance matrix is
274 scaled by the diagonal covariance matrix (Fox et al., 2014):

$$275 \quad C_{\xi\beta} = \frac{c_{\xi\beta}}{\sqrt{c_{\xi\xi}}\sqrt{c_{\beta\beta}}}. \quad (14)$$

276 The correlation matrix for the reference model is shown in Fig. 3d. The diagonal correlation
277 values are 1 and off-diagonal ones are dominantly negative, indicating anti-correlated uncertainties
278 (Fig. 3d), which suggests exhumation parameters were not resolved independently by the modeling.
279 In fact, it is expected to have the anti-correlation, because, given two steps of rock exhumation,
280 decreasing the exhumation during one step would increase that of the other step.

281

282 6. Dependence on model parameters and proposed solutions

283 Here we use the Denali data set for demonstrating the influences of (1) the initial
284 geothermal parameters, (2 and 3) the *a priori* mean and variance values of the exhumation rates,
285 and (4) time interval length on the inverted exhumation history. Also discussed in this section are
286 the solutions for optimizing the model setup for these parameters.

287

288 6.1. Dependence on initial thermal model

289 Different initial model geothermal parameters would lead isotherms to shift either
290 downward to greater depths or upwards to the Earth surface, and either compression or expansion

295 among isotherms. Therefore, the initial thermal models have systematic influence on the closure
296 depths and consequently the *a posteriori* exhumation.

297 This is demonstrated by modelling experiments presented in Figure 4. Using a relatively
298 lower initial geothermal gradient produces relatively higher *a posteriori* exhumation rates
299 (comparing the models shown in Figs. 4a-4f), and *vice versa*. Such an influence is significant even
300 for the time and elevation intervals with multiple age constraints (10-5.0 Ma). For example, using
301 relatively lower geothermal gradients of <22 °C/km would yield significantly higher average
302 exhumation rates of >0.75 km/Myr for the last two stages (<5 Ma) (Figs. 4a-4c) than those (<0.6
303 km/Myr) using higher initial geothermal gradients of ≥ 26 °C/km (Figs. 4d-f). Further, it is also
304 shown that models using higher and lower prior geothermal gradients of <20 °C/km (Figs. 4a-4b)
305 and >30 °C/km (Figs. 4e-4f) yield worse misfits ($\Phi_{\% po} > 1$) for the observed present-day
306 geothermal gradient than those ($\Phi_{\% po} < 1$) using medium initial gradients (22-26 °C/km) (Figs. 3
307 and 4c-4d).

308 These results highlight the importance of taking geothermal parameters into account in
309 inverting the exhumation history and model evaluation. We proposed to run a set of models using
310 different *a priori* geothermal parameters, especially the initial geothermal gradient, to search for
311 the proper initial geothermal setup that provides reasonable fits to both the ages and the modern
312 geothermal gradient (see section 7 for details).

313

314 6.2. Dependence on the *a priori* exhumation rate

315 Both the mean and variance of the *a priori* exhumation rate have important influences on
316 the model solution for the maximum likelihood estimation method. Our modeling experiments
317 show that the mean value of the *a priori* exhumation has systematic influences on the inverted

Deleted: 8

Deleted: Worth noting is that the models using relatively lower (16-20 °C/km, Figs. 4a-4b) and higher (30-34 °C/km, Figs. 4e-4f) initial geothermal gradients yield relatively worse misfits (>1) than those using medium initial gradients (22-26 °C/km) (Figs. 3 and 4c-4d), suggesting that the modern geothermal gradient can be used as a constraint for the initial geothermal model.

326 exhumation. Similar to the reference model, exhumation of the preceding three stages (25-17.5
327 Ma) without age constraints is the same as the *a priori* input. For the following stages, a relatively
328 higher mean value of the *a priori* exhumation results in relatively lower *a posteriori* exhumation
329 rates (comparing different models presented in Fig. 5). For example, models using the mean *a*
330 *priori* exhumation of ≤ 0.4 km/Myr yield a *posterior* exhumation of 0.5-0.9 km/Myr for the stages
331 < 7.5 Ma (Figs. 5a-5c), whereas those using a higher *a priori* value (≥ 0.6 km/Myr) result in a
332 *posterior* exhumation of 0.45-0.6 km/Myr for the same stages (Figs. 5d-5f). This is because a
333 relatively higher *a priori* value, which would be used for calculating thermal models, would lead
334 to a quicker increase in geothermal gradient and thus relatively shallower closure depths and
335 relatively lower exhumation rates.

336 The variance of the *a priori* exhumation rate has important influence on both the
337 exhumation rates and the posterior variance. Models with lower *a priori* variances yield less
338 variations in the *a posteriori* exhumation history, and *vice versa* (comparing models in Fig. 6).
339 Further, models using the input variance of the *a priori* exhumation of 0.2-0.3 km/Myr (40-60%
340 of the mean value), the variation of the inverted exhumation history becomes stable (Figs. 3, 6c-
341 6d). Given that the uncertainty of the input age data, which is often 10%-20% at a two-sigma level,
342 larger variance of the inverted exhumation would be unreasonable (Figs. 6e-6f), especially when
343 multiple age data are available at different elevations.

344 We proposed to run a set of models using different *a priori* mean value of erosion rates to
345 search for the one that provides appropriate fits to both the ages and the modern geothermal
346 gradient. As to the *a priori* variance, we propose to use a value 30-70% of the *a priori* erosion rate,
347 Future applications of the method may need to test a set of the variance inputs so as to get a stable

Deleted: 5

Deleted: 8

Deleted: 7

Deleted: of erosion rates

Deleted: relative uncertainty

Deleted: of

Deleted: mean value

355 exhumation output. Larger *a priori* variance would lead to larger uncertainties for the exhumation
356 rates, which is unreasonable and non-meaning for geological studies.

358 6.3. Dependence on time interval length

359 Constraining the onset time of major changes in exhumation rates is one of the important
360 tasks for inverting the exhumation history from thermochronologic data. Using a large time
361 interval length cannot accurately capture the potential transition time of exhumation rates. As
362 shown in the Figs. 7b-7d, models using time lengths of ≤ 3.5 Ma show an abrupt increase in
363 exhumation at 7-6 Ma, consistent with that shown in AER plot. However, the models using a large
364 time interval length (≥ 4.5 Ma) overestimate the onset time of the enhanced exhumation (Figs. 7e-
365 7f). Further, a relatively shorter time length would smooth temporal changes in exhumation rates,
366 leading to an underestimating of the variations. For example, as shown in the Fig. 7a, the model
367 using a relatively shorter time length (0.5 Ma) yields an exhumation variation between 0.35-0.60
368 km/Myr, significantly lower than those using relatively larger time interval lengths (Figs. 7b-7f).
369 In addition, a shorter time length also significantly increases the computational time and resources,
370 especially when processing a large number of vertical transects.

371 Given the interests in major exhumation changes, we propose the time interval length (Δt)
372 should be optimized for constraining the transitional time and the associated exhumation changes.
373 Therefore, the time interval length should be set as the absolute uncertainty at two sigma levels at
374 the break point (τ_b) (equation 15). If the break point is unclear in AER, we suggest to use the
375 absolute uncertainty at two-three sigma levels at the median age value (τ) (equation 15), so as to
376 focus on the time intervals where ages cluster.

$$377 \Delta\tau = \begin{cases} \delta\tau_b, & \text{if a break in slope exists} \\ \delta\tau, & \text{if no clear break in AER} \end{cases} \quad (15)$$

Deleted: propose

379 where δ is the relative age uncertainty at two sigma levels, varying between 10%-20% among
380 different studies. Following this method, the Denali case should use a time length of ~ 1.5 Ma (7
381 Ma \times 20%), slightly lower than that used in the reference model (Fig. 3).

382

383 7. A new modeling guideline

384 ~~Following the modelling protocol outlined above, a stepwise modeling guideline is~~
385 ~~developed~~ for addressing the model dependencies on the initial geothermal parameter, the *a priori*
386 exhumation rates and time interval length. As illustrated in the Figure 8, the approach includes the
387 following three steps.

388 (i) Estimating a time-averaged erosion rate. Dividing each nominal closure depth, which
389 can be estimated from the nominal closure temperatures and the modern geothermal gradient, by
390 the corresponding age results in a time-averaged erosion rate. Then, a mean value can be
391 determined by averaging the rates. Such a mean value and assumed variance (30% - 50% in this
392 work) will be used as the *a priori* erosion rate.

393 (ii) Optimizing the fit to the modern geothermal gradient. This step runs a set of inversion
394 models (20 in this work) using different geothermal gradients, ranging from ~~50%~~ to 120% of the
395 modern value, together with the *a priori* erosion rate estimated in the first step, for determining
396 the initial geothermal gradient that yields the maximum fit to the modern value, i.e., the minimum
397 Φ_T (equation 13).

398 (iii) Optimizing the fit to both the age data and the geothermal gradient. Given the model
399 dependence on the geothermal parameters (see section 6.1), a comprehensive evaluation of the
400 models should assess not only the age misfit (Φ_T), but also that of the geothermal gradient (Φ_T). In
401 the third step, a set of inversion models (20 in this work) are run using different *a priori* erosion

Deleted: develops

Deleted: 60

409 rates, changing from 10% to 200% of the mean value estimated in the first step, together with the
410 estimated geothermal gradient by the second step, to search for the model that provides the best fit
411 to both the age data and the modern geothermal gradient. This study uses the following compound
412 misfit function to evaluate the models:

$$\Phi = \Phi_r + \Phi_g/\sqrt{N}, \quad (17)$$

413 where Φ_r and Φ_g are misfit values for the age and geothermal gradient calculated using the
414 equations 12 and 13, and N is the number of age inputs. Dividing Φ_g by the square root of N in this
415 equation, as also done for calculating the Φ_r (equation 12), means that the modern geothermal
416 gradient is given the same weight as an age input for evaluating the model.
417
418

419 **8. Synthetic models for testing the new modeling guideline**

420 We firstly test our stepwise inversion scheme by synthetic datasets generated by thermo-
421 kinematic models modified from Braun et al. (2012) (their Fig. 9). The synthetic age dataset is
422 produced by Pecube using the following parameters: a steady-state topography with a 20-km
423 wavelength and a 2-km relief, a model block thickness of 30 km with a basal temperature of 600 °C,
424 a thermal diffusivity of 25 km²/Myr, a sea level temperature of 10 °C, a lapse rate of 5 °C/km.
425 Worth noting is that these parameters are the same as Braun et al. (2012). For model details, see
426 Braun et al. (2012). For model setup see the supplementary Figure S1.

427 Synthetic AFT and AHe ages (supplementary Tables T1) were calculated for both surface
428 and borehole samples for four different exhumation histories. The synthetic models a and b are
429 characterized by a sudden decrease in exhumation rate from 1 km/Myr to 0.1 km/Myr (model-a,
430 same as the that shown in the Fig. 9 of Braun et al. 2012) and 0.3 km/Myr (model-b) at 5 Ma,
431 respectively. The models c and d include a sudden increase in exhumation rate from 0.3 km/Myr

Deleted: 20

Deleted: 150

434 (model-c) and 0.1 km/Myr (model-d) to 1 km/Myr at 5 Ma, respectively. All models start from 40
435 Ma. Except for the synthetic age data (plotted in the first row of Fig. 9), these four models generate
436 modern geothermal gradients of 26.5 °C/km, 28.6 °C/km, 35.5 °C/km and 34 °C/km for the
437 uppermost 2-km crust, respectively.

438 Inversion of rock exhumation history used a start time of 20 Ma and a time interval length
439 of 1.0 Myr for all synthetic datasets, which were assigned with a 6% uncertainty. As shown by the
440 modelling output visualized in Fig. 9a, our inversion of the rock exhumation from the synthetic
441 dataset-a finds an optimal initial geothermal gradient of 22 °C/km and *a priori* rate of 0.85 ± 0.25
442 km/Myr, and yields a decrease in exhumation rates from ~0.9 km/Myr (before 6 Ma) to 0.3-0.1
443 km/Myr (4-0 Ma), via a gradual decrease during 6-4 Ma. The data has no resolution for the
444 exhumation history before 10 Ma. Comparing to the synthetic model (abrupt decrease from 1
445 km/Myr to 0.1 km/Myr at 5 Ma), the rates before 5 Ma are underestimated by 0.1 km/Myr, whereas
446 the values after 5 Ma overestimated by 0.1-0.3 km/Myr.

447 The inversion for the synthetic dataset-b results in an optimal initial geothermal gradient
448 of 21.7 °C/km and *a priori* rate of 0.81 ± 0.24 km/Myr, and an increase in exhumation rates from
449 ~0.85 (before 5 Ma) km/Myr to 0.4-0.5 km/Myr (4-0 Ma), via a gradual decrease during 5-4 Ma
450 (Fig. 9b). Comparing to the synthetic model (abrupt decrease from 1 km/Myr to 0.3 km/Myr at 5
451 Ma), the rates before 5 Ma are underestimated, whereas the values before 5 Ma are overestimated
452 by ~0.1-0.2 km/Myr.

453 The inversion for the synthetic dataset-c yields an optimal initial geothermal gradient of
454 24.3 °C/km and *a priori* rate of 0.55 ± 0.17 km/Myr, and a decrease in exhumation rates from
455 ~0.45-0.3 km/Myr (before 5 Ma) to 1.0 km/Myr (3-0 Ma), via a gradual increase during 5-3 Ma
456 (Fig. 9c). Comparing to the synthetic model (abrupt decrease from 0.3 km/Myr to 1.0 km/Myr at

Formatted: Font: Italic

457 5 Ma), the rates during 5-3 Ma are underestimated, whereas the rates before 5 Ma overestimated
458 by 0-0.15 km/Myr.

459 The inversion for the synthetic dataset-d produces an optimal initial geothermal gradient
460 of 24.5 °C/km and *a priori* rate of 0.25 ± 0.08 km/Myr, and an increase in exhumation rates from
461 ~0.1-0.2 km/Myr (before 5 Ma) to 1.0 km/Myr (3-0 Ma), via a gradual decrease during 5-3 Ma
462 (Fig. 9d). Comparing to the synthetic model (abrupt decrease from 1 km/Myr to 0.3 km/Myr at 5
463 Ma), the rates before 5 Ma are slightly overestimated, whereas the values during 5-3 Ma are
464 underestimated.

465 To summarize, the inverted rock exhumation histories for the four synthetic datasets match
466 the whole picture of the synthetic “truth”, but the variations in exhumation are underestimated,
467 and the sharp changes at 5 Ma are smoothed. It is worth noting that inversions using only surface
468 samples produce similar results (supplementary Fig. S2).

469

470 **9. Natural examples for testing the new modeling guideline**

471 Below we use three examples to demonstrate our new method. The Denali data is used
472 again for demonstrating the efficiency of our method in finding the proper initial geothermal
473 gradient and the *a priori* exhumation rate. Then, we further test our method using the Himalayan
474 Dhanladar range and KTB borehole (the Continental Deep Drilling Project in Germany)
475 thermochronologic data for representing regions of fast and slow erosion, respectively.

476 **9.1 The Denali transect**

477 Using the stepwise inversion modeling guideline, the Denali transect yields an exhumation
478 history generally similar with that of the reference model (Fig. 10a). Differences in the *a priori*
479 parameters include that the new inversion finds and uses an initial geothermal gradient of

Deleted: 8

Deleted: Examples

Formatted: Font: Italic

Deleted: 8

Deleted: strategy

484 25.2 °C/km (slightly higher than that of the reference model), *a priori* erosion rate of 0.46 ± 0.23
485 km/Myr (slightly lower than that of the reference model) and a time interval length of 1.5 Ma. The
486 combination of these *a priori* parameters result in a major increase in erosion rate, to 0.55-0.6
487 km/Myr at 6 Ma, which is 1.5 Myr latter than that of the reference model (7.5 Ma). The subtle
488 differences from the reference model mainly result from the time interval length used in these
489 models. Comparing the misfit values, the new model produces slightly better fits than the reference
490 model, with the *a posterior* misfit values of 1.81 and 0.11 for the observed age and geothermal
491 data.

493 9.2 Himalayan Dharladar range transect

494 AFT and ZHe data from the Dharladar range in the northwestern Himalayas, reported in
495 the publications by Deeken et al. (2011) and Thiede et al. (2017) are used as an example for regions
496 of young cooling ages and fast exhumation. The samples were collected in an elevation range
497 between 1.5 and 4.5 km, covering a topographic relief of 3 km within a spatial distance of ~15 km
498 on the hanging wall of the main central thrust of the Himalayan fold-thrust-belt (Deeken et al.,
499 2011; Thiede et al., 2017). AER slope regression of ZHe and AFT ages performed in Deeken et al.
500 (2011) produced apparent erosion rates of ~2.8 km/Myr and ~0.2 km/Myr for the time intervals
501 6.4–14.5 Ma and 1.7–3.7 Ma, respectively, implying a potential increase in erosion rates at ~3.7-
502 6.4 Ma. Using geothermal gradients of 25–45 °C/km, time-averaged erosion rates were estimated
503 as 0.8–2.0 km/Myr since 3.7 Ma (Deeken et al., 2011).

504 The modelling of the Dharladar range data uses a modern geothermal gradient constraint
505 of 45 ± 8 °C/km (Deeken et al., 2011). The relatively large uncertainty is assigned for the
506 geothermal gradient, because of the absence of direct geothermal measurements in the study area.

Deleted: AER slope regression suggests an increase in apparent erosion rates from ~0.2 km/Myr to ~2.8 km/Myr at ~3.7-6.4 Ma

Deleted: and 0.8-1.7 km/My

Deleted: and 14.5 Ma, respectively

532 Our exhumation inversion for the AER data using the stepwise modeling guideline yields relatively
533 slow rates of 0.1-0.6 km/Myr and fast rates of 1.2-1.6 km/Myr before and after ~3 Ma, respectively
534 (Fig. 10b). The abrupt increase of exhumation rates at ~3 Ma is generally consistent with the
535 estimates from the slope regression results of Deeken et al. (2011). However, the inverted
536 exhumation rates since 3 Ma are significantly lower than the estimation from the AER slope (~2.8
537 km/Myr), which is likely due to the overestimation of exhumation of the AER slope due to
538 topographic perturbation of isotherms. Such a perturbation is a function of exhumation rates: the
539 higher the exhumation, the larger the perturbation (Glotzbach et al., 2015). The modelling yields
540 a history of the geothermal gradient that gradually increases to a modern value of ~46 °C/km, close
541 to the input value (45 ± 8 °C/km).

542

543 9.3 KTB borehole

544 The KTB borehole yields a large thermochronologic and geochronologic age data
545 (Warnock and Zeitler, 1998; Stockli and Farley, 2004). Previous studies suggest the borehole are
546 truncated by multiple faults, which offset the age-depth relationship (Wagner et al., 1997). Here
547 we use the data at depths shallower than 1 km, where data are abundant and have linear relationship
548 with depths.

549 The KTB apatite, zircon and titanite (U-Th)/He (AHe, ZHe and THe) and AFT age data
550 vary largely between 85-50 Ma. These clustered ages have been interpreted as indicating a late
551 Cretaceous phase of exhumation, followed by slow exhumation (Wagner et al., 1997; Stockli and
552 Farley, 2004), as also shown by previous thermal history reconstructions based on k-feldspar
553 ⁴⁰Ar/³⁹Ar data (Warnock and Zeitler, 1998).

566 Our modeling, using the AER data and a modern geothermal gradient of 27.5 ± 2.8 °C/km
567 (Clauser et al., 1997), shows that elevated exhumation rates (0.1-0.13 km/Myr) between 80-50 Ma,
568 followed by slower exhumation rates of ~0.04 km/Myr (Fig. 10c), are similar to previous estimates
569 (Wagner et al., 1997; Warnock and Zeitler, 1998; Stockli and Farley, 2004). Associated with
570 changes in exhumation, geothermal gradient gradually decreases from the peak values at 70-60
571 Ma to a value of ~28 °C/km at the present-day.

572

573 **10. Conclusion**

Deleted: 9

574 The *a priori* information has important effects on the inversion results using the least-
575 squares inversion method. Our study demonstrates the importance of geothermal gradient and the
576 *a priori* exhumation rate in estimating the exhumation history from the thermochronology data.

577 To take into account the geothermal data into the exhumation history inversion, we outlined a
578 stepwise inversion method that first searches for the appropriate initial geothermal gradient, which
579 is then used in the modelling searching for the *a priori* exhumation rate. Our modelling guideline
580 produces exhumation history and geothermal gradient that provide reasonable fits for both the
581 observed AER and modern geothermal data, as tested by datasets of both synthetic models and
582 natural samples. The code and data used in this work are available in GITHUB

758 **Figures captions:**

760 Figure 1. Schematics showing the relationship among closure depth (z_c), topography and its
761 perturbation (p). The parameter h denotes the difference between the sample and the mean
762 elevation, and z_m the depth of the closure temperature (T_c , the lower dashed line) derived from
763 the mean elevation (upper dashed line) and initial temperature field ($T_{initial}$) and exhumation
764 history ($\dot{\epsilon}$).

765

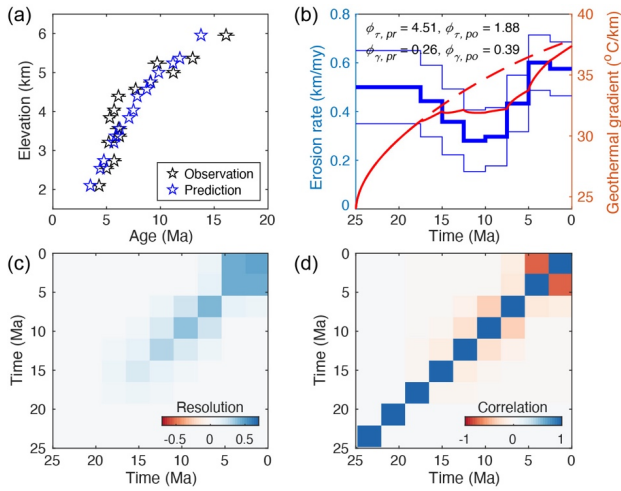

766

767

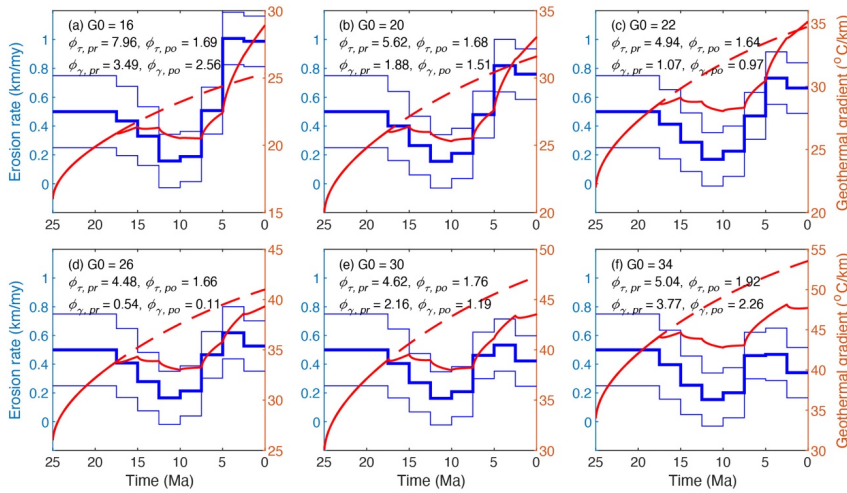

768 Figure 2. (a) Distribution of AFT age data (pentagons, colored by age values) over the elevation
769 contour map computed using the SRTM30 data of the Denali massif in Alaska. AFT data
770 sourced from Fitzgerald et al. (1995). (b) AER and the slope fitting results using isoplotR
771 (Vermeesch, 2018). AER fitting of ages older than 6.7 Ma yields a slope of 0.17 ± 0.04 km/Myr;
772 whereas the fitting of ages between 6.5 Ma and 4.3 Ma produces a slope of 1.2 ± 0.6 km/Myr
773 and an intercept at -3.3 ± 3.4 km. The upper and lower dashed lines denote the mean elevation
774 (4.02 km) and the depth of the nominal closure temperature (110 °C), calculated using the
775 modern geothermal gradient (38.9 °C/km) and the surface temperature (-12 °C).

776

777

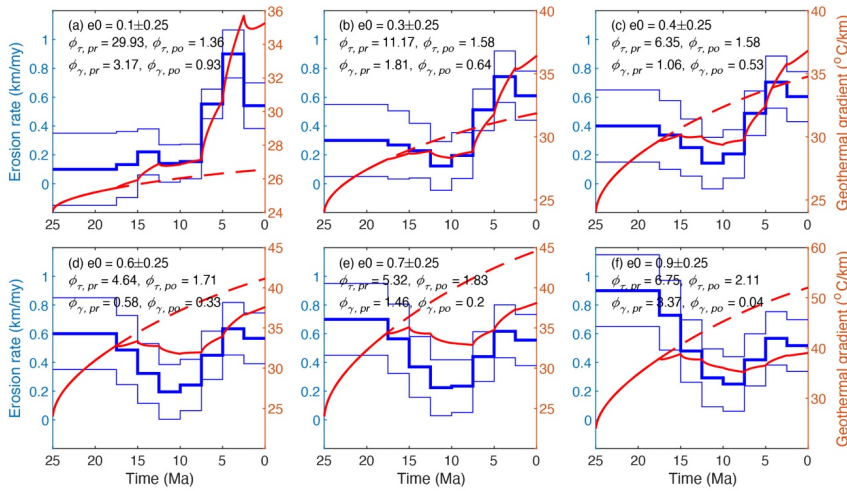

778 Figure 3. Inputs and outputs of the reference model for the Denali AFT. (a) Comparison between
 779 the observed (in black) and predicted (in blue) AER. (b) The *a posteriori* exhumation history
 780 generated by the reference model. Thick and thin lines are the mean and one standard deviation
 781 of the inverted exhumation history. The red dash and solid lines are the history of the geothermal
 782 gradients, predicted by the *a priori* and *a posteriori* models, respectively. (c) and (d) Plots of the
 783 resolution and correlation matrix.

784

785 Figure 4. Histories of exhumation and geothermal gradients, predicted by models using different
 786 initial geothermal gradients between 18 °C/km and 34 °C/km. The blue thick and thin lines are
 787 the mean and one standard deviation of the inverted exhumation history. The red dash and solid
 788 lines are the history of the geothermal gradients, predicted by the *a priori* and *a posterior*
 789 models, respectively. Except for the initial geothermal gradient, other parameters are the same as
 790 the reference model. Comparing to the reference model which used an initial geothermal gradient
 791 of 24 °C/km (Fig. 3), models using a lower initial geothermal gradient yield relatively higher
 792 exhumation rates (panels a-c), whereas those using a higher gradient produce lower exhumation
 793 rates (panels d-f).

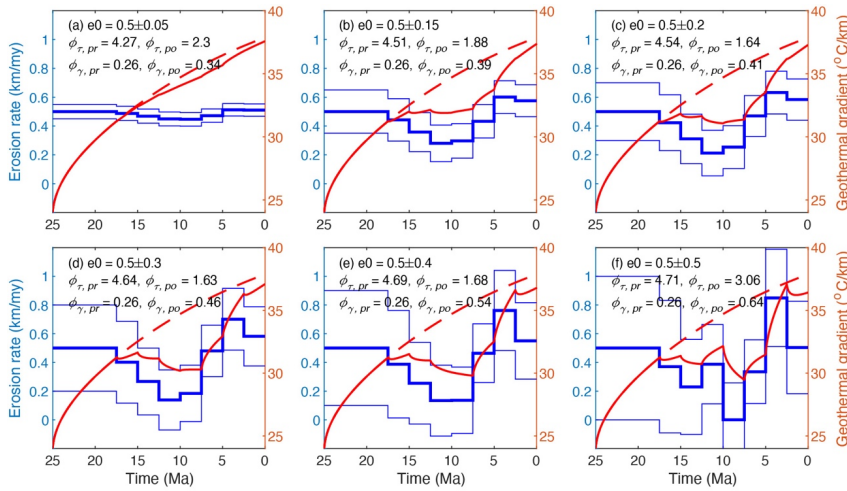

794

795

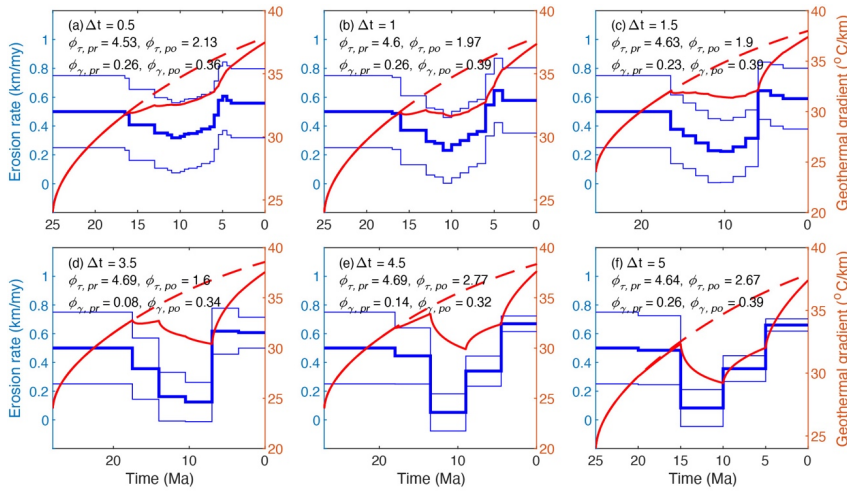

796 Figure 5. Histories of exhumation and geothermal gradients, predicted by models using different
 797 *a priori* mean values of the exhumation rates, ranging from 0.1 km/Myr to 0.9 km/Myr. Other
 798 parameters are the same as the reference model. For explanation of the plotted lines, see Figure
 799 4. Comparing to the reference model which used *a priori* mean exhumation of 0.5 km/Myr (Fig.
 800 3), models using a lower *a priori* exhumation yield relatively higher exhumation rates for the last
 801 three stages (7.5 - 0 Ma) (panels a-c), whereas those using a higher *a priori* exhumation produce
 802 lower exhumation rates for the last three stages (panels d-f).

803

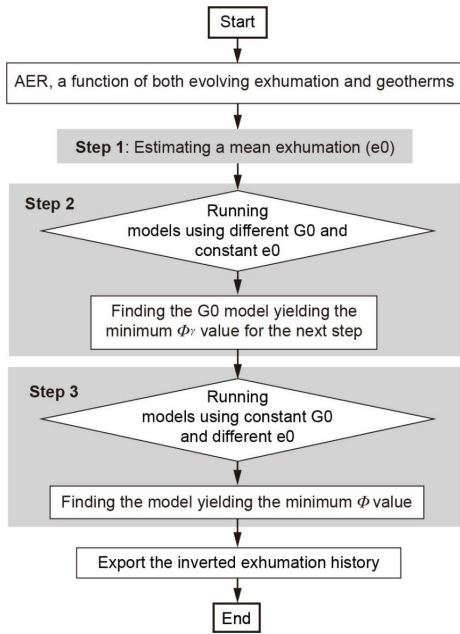

804
 805 Figure 6. Histories of exhumation and geothermal gradients, predicted by models using different
 806 *a priori* variance values (between 0.05 km/Myr and 0.5 km/Myr) of the exhumation rates (0.5
 807 km/ Myr). Other parameters are the same as the reference model. For explanation of the plotted
 808 lines, see Figure 4. Comparing to the reference model which used *a priori* variance of the
 809 exhumation (0.25 km/Myr) (Fig. 3), models using a lower *a priori* variance yield limited
 810 variations and uncertainties in exhumation (panels a-c), whereas those using a higher *a priori*
 811 variance produce larger variations and uncertainties (panels d-f).

812

813
 814 Figure 7. Histories of exhumation and geothermal gradients, predicted by models using different
 815 time interval lengths. Other parameters are the same as the reference model. For explanation of
 816 the plotted lines, see Figure 4. Comparing to the reference model which used a time interval
 817 length of 2.5 Ma (Fig. 3), models using smaller time interval lengths yield lower variations in
 818 exhumation (panels a-c) than other using larger time interval lengths (panels d-f).

819

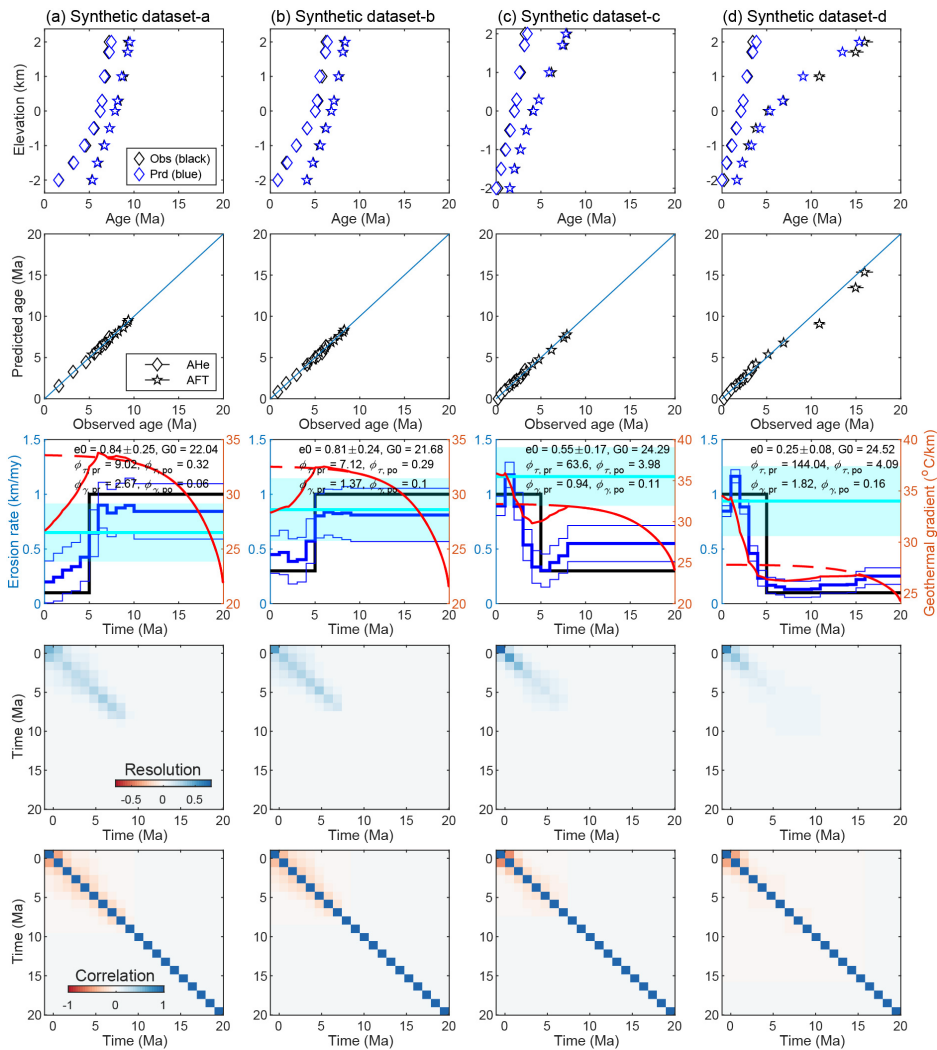

820

821 Figure 8. Flow chat of a stepwise modeling method, which includes three main steps. The first
 822 step estimates a mean exhumation rate (e_0) using the nominal closure temperatures, modern
 823 geothermal gradient and sample ages. The mean rate is used in the second step which runs a set
 824 of models using different initial geothermal gradients for optimizing the initial geothermal
 825 model. The third step runs a set of models using different *a priori* exhumation rates, which is
 826 generated around the mean rate, and the optimized initial geothermal model by the second step,
 827 to find the best model that yields the minimum misfit to both age data and modern geothermal
 828 gradient.

832
 833 Figure 9. The best-fit model for the synthetic dataset-a, -b, -c and -d using the modeling method
 834 shown in figure 8. First row: Comparison between the observed (in black) and predicted (in blue)
 835 AER. Second row: plots of observed and modeled ages. Third row: Histories of exhumation and
 836 geothermal gradients. The black line marks the “true” exhumation history used for simulating the

837 age dataset, whereas the blue thick and thin lines are the mean and one standard deviation of the
838 inverted exhumation. The red dash and solid lines are the history of the geothermal gradients,
839 predicted by the *a priori* and *a posterior* models, respectively, whereas the cyan line and polygon
840 denotes the modern geothermal gradient. Fourth and bottom row: Plots of the resolution and
841 correlation matrix.

842

843
 844 Figure 10. The best-fit model for the Denali (a), Dhanladar range (b) and upper KTBT (c)
 845 transects, using the modeling method shown in figure 8. See Fig. 8 for panel interpretations.
