12 **Abstract**

13 Adsorption and desorption of gases on liquid or solid substrates are involved in multiphase
14 processes and heterogeneous chemical reactions. The desorption energy (E_{des}^0), which depends on
15 the intermolecular forces between adsorbate and substrate, determines the residence time of
16 chemical species at interfaces. We show how E_{des}^0 and temperature influence the net uptake or
17 release of gas species, the rates of surface-bulk exchange and surface or bulk reactions, and the
18 equilibration timescales of gas-particle partitioning. Using literature data, we derive a
19 parameterization to estimate E_{des}^0 for a wide range of chemical species based on the molecular
20 mass, polarizability, and oxygen to carbon ratio of the desorbing species independent of substrate-
21 specific properties, which is possible because of the dominant role of the desorbing species'
22 properties. Correlations between E_{des}^0 and the enthalpies of vaporization and solvation are rooted
23 in molecular interactions. The relation between E_{des}^0 and desorption kinetics reflects the key role
24 of interfacial exchange in multiphase processes. For small molecules and semi-volatile organics
25 (VOC, IVOC, SVOC), E_{des}^0 values around 10 - 100 kJ mol⁻¹ correspond to desorption lifetimes
26 around nanoseconds to days at room temperature. Even higher values up to years are obtained at
27 low temperatures and for low volatile organic compounds (LVOC, ELVOC/ULVOC) relevant for
28 secondary organic aerosols (SOA). Implications are discussed for SOA formation, gas-particle
29 partitioning, organic phase changes, and indoor surface chemistry. We expect these insights to
30 advance the mechanistic and kinetic understanding of multiphase processes in atmospheric and
31 environmental physical chemistry, aerosol science, materials science, and chemical engineering.

32

33

34 **1. Introduction**

35 The interaction of gases with condensed phase matter via heterogeneous or multiphase reactions
36 is of importance for a variety of disciplines such as chemical engineering, catalysis, materials
37 science, and environmental and atmospheric chemistry (Cussler, 2009; Chorkendorff and
38 Niemantsverdriet, 2007; Finlayson-Pitts and Pitts, 2000; Ravishankara, 1997; Solomon, 1999;
39 Hoffmann et al., 1995; Beller et al., 2012; Hanefeld and Lefferts, 2018). In the atmosphere, gas-
40 particle interactions and multiphase chemical processes involve gaseous and condensed-phase
41 species manifesting in condensation, gas-particle partitioning, and alteration in the
42 physicochemical properties of aerosol particles and cloud droplets (Pöschl et al., 2007; Kolb et al.,
43 2010; Rudich et al., 2007; George and Abbatt, 2010; Pöschl and Shiraiwa, 2015; Moise et al.,
44 2015; Ammann et al., 2013; Crowley et al., 2013; Kroll et al., 2011; Donahue et al., 2011; Jimenez
45 et al., 2009; Abbatt and Ravishankara, 2023; Ravishankara, 1997; Penkett et al., 1979; Hoffmann
46 and Edwards, 1975; Davidovits et al., 2006). The dramatic effects of multiphase reactions in the
47 atmosphere are most impressively demonstrated by the large-scale stratospheric ozone depletion
48 (ozone hole) over the south pole during Antarctic winter and spring, where inactive gaseous
49 chlorine species are converted to active gas species on cloud particles (Solomon, 1999; Rowland,
50 1991; Peter, 1997; Koop et al., 1997; Muller et al., 1997; Carslaw et al., 1997).

51 Atmospheric aerosol particles and environmental interfaces are often chemically complex
52 systems comprising multiple components in multiple phases. The large compositional variety of
53 airborne particulate matter and gas species including reactive radicals, oxidants, and volatile
54 inorganic and volatile organic compounds (VOCs), in addition to the wide temperature and
55 humidity range present in the atmosphere, poses challenges to resolve multiphase chemical
56 kinetics on a molecular level. The underlying molecular processes are important for the scientific

57 understanding and reliable description of gas uptake and chemical transformation of aerosols
58 (Shiraiwa et al., 2011a; Berkemeier et al., 2013; Zhou et al., 2013; Abbatt et al., 2012; Kolb et al.,
59 2010; Schwartz, 1986; Hanson and Lovejoy, 1995; Hanson et al., 1996; Shen et al., 2022; Willis
60 and Wilson, 2022), the chemical evolution of secondary organic aerosol (SOA) including the
61 partitioning of semivolatile species (Shiraiwa and Seinfeld, 2012; Shiraiwa et al., 2013b; Perraud
62 et al., 2012; Donahue et al., 2011; Ingram et al., 2021), and the impact of multiphase reactions on
63 the particles' activation as cloud condensation nuclei (CCN) or ice-nucleating particles (INPs)
64 (Slade et al., 2015; Slade et al., 2017; Petters et al., 2006; Wang et al., 2012; Wang and Knopf,
65 2011; Knopf et al., 2018; Knopf and Alpert, 2023).

66 Atmospheric multiphase reactions usually involve an adsorbed state of gas species at the surface
67 of a liquid or solid material (Langmuir, 1918, 1916, 1915; Iupac, 1997), which can be regarded as
68 physisorption or chemisorption depending on the nature and intensity of the surface interaction.
69 Physisorption is caused by weak intermolecular interactions (van der Waals, hydrogen bond, ionic
70 and hydrophobic interactions, Table 1) with energies up to $\sim 50 \text{ kJ mol}^{-1}$, whereas chemisorption
71 involves changes of chemical bonds with higher interaction energies (Desjonqueres and Spanjaard,
72 1996; Masel, 1996; Pöschl et al., 2007). The phenomenon of reversible adsorption is easiest to
73 depict on solid surfaces but applies also to liquid surfaces, where it is coupled to the exchange with
74 the bulk liquid (Langmuir, 1918, 1916, 1915; Nathanson, 2004; Ringeisen et al., 2002a, b; Behr et
75 al., 2001; Morris et al., 2000; Masel, 1996; Nathanson et al., 1996; Rettner et al., 1996; Donaldson
76 and Anderson, 1999; Donaldson et al., 1995; Donaldson, 1999; Pöschl et al., 2007).

77 According to the Frenkel equation, the desorption lifetime (τ_{des}) of a surface-adsorbed chemical
78 species (adsorbate) follows an Arrhenius-type behavior (Arrhenius, 1889b; Arrhenius, 1889a;
79 Laidler, 1949; Frenkel, 1924; Laidler et al., 1940):

80
$$\tau_{\text{des}} = \frac{1}{k_{\text{des}}} = \frac{1}{A_{\text{des}}} e^{\left(E_{\text{des}}^0 / (RT) \right)}, \quad (1)$$

81 where k_{des} is a first-order desorption rate coefficient, A_{des} is a pre-exponential factor, in more
82 detail discussed below, R is the gas constant, and T is the temperature. E_{des}^0 is the desorption
83 energy with the energy reference of the gas molecule at rest at $T = 0$ K. E_{des}^0 is referred to as the
84 activation energy of desorption. In terms of the theory of the kinetics of desorption, desorption is
85 always considered an activated process, independent of whether E_{des}^0 corresponds to just the
86 energy difference between gas and adsorbed state or also include an energy barrier on top of that
87 (Knopf and Ammann, 2021). In case of physisorption, E_{des}^0 is equal to the negative value of the
88 enthalpy of adsorption with a correction for the change in degree of freedom between gas and
89 adsorbed phase (see below and Knopf and Ammann, 2021; Kolasinski, 2012). In turn, in the other
90 direction, for the kinetics of the process from the gas phase to the adsorbed state, the adsorption
91 rate normalized to the gas kinetic collision rate is often expressed as the surface accommodation
92 coefficient as discussed below.

93 Atmospheric trace gases and water vapor adopt reversibly adsorbed states on aerosol, cloud, and
94 ground surfaces over a wide range of temperatures from below 200 to above 300 K. The rate of
95 interfacial processes, which may involve reversible, reactive and catalytic steps, generally depends
96 on the concentration of surface-adsorbed reactants and hence on τ_{des} . Especially at low
97 temperatures, high values of τ_{des} can (over)compensate for the low rates of thermally activated
98 chemical reactions and diffusion and thereby enhance the overall gas uptake (Ammann et al., 2013;
99 Crowley et al., 2013; Kolb et al., 2010; Pöschl et al., 2007).

100 Factors influencing gas uptake are competitive co-adsorption of other species (Pöschl et al.,
101 2001; Pöschl et al., 2007; Slade and Knopf, 2014; Kaiser et al., 2011; Springmann et al., 2009;

102 Shiraiwa et al., 2009), solvent dynamics and polarization effects (Ringeisen et al., 2002b; Morris
103 et al., 2000; Klassen et al., 1997; Nathanson et al., 1996; Jungwirth et al., 2006), thermodynamics
104 and kinetics of surface – bulk exchange and bulk diffusivity in viscous liquids (Lakey et al., 2016;
105 Berkemeier et al., 2016; Steimer et al., 2015; Shiraiwa et al., 2014; Shiraiwa et al., 2013a; Houle
106 et al., 2018; Wiegel et al., 2017; Davies and Wilson, 2015; Marshall et al., 2016; Marshall et al.,
107 2018), and phase separations or heterogeneous structures in the condensed phase (You and
108 Bertram, 2015; You et al., 2014; You et al., 2012; Bertram et al., 2011; Huang et al., 2021).

109 Apart from adsorption and desorption, further processes influencing gas-particle interactions and
110 multiphase chemical kinetics include mass transport to the condensed phase by gas-phase diffusion
111 and accommodation at the interface; chemical reactions at the surface following Langmuir-
112 Hinshelwood or Eley-Rideal type mechanisms; dissolution, diffusion, and chemical reactions in
113 the bulk. Together with desorption, these processes may proceed sequentially or in parallel for
114 multiple chemical species, which can be described by appropriate differential equations and
115 numerical models (Shiraiwa et al., 2010; Shiraiwa et al., 2009; Ammann and Pöschl, 2007; Pöschl
116 et al., 2007; Shiraiwa et al., 2012; Wilson et al., 2022).

117 Traditionally, the uptake of trace gases by solid and liquid particles or substrates has often been
118 analyzed by the so-called resistor model, treating each of the above processes in analogy to parallel
119 or serial resistors in an electrical circuit (Schwartz, 1986; Worsnop et al., 2002; Hanson and
120 Lovejoy, 1995; Hanson et al., 1994; Ammann et al., 2013; Crowley et al., 2010). Despite
121 constraints and limitations such as the required approximations regarding steady state and mixing,
122 and a limited capability to describe multicomponent systems, the resistor model has proven to be
123 useful for the investigation and characterization of various processes and substrates, including
124 mineral dust, ice, sulfuric acid, and organic and inorganic particles (Pöschl et al., 2007; Hanson,

125 1997; Davidovits et al., 2006; Crowley et al., 2010; Kolb et al., 2010; Hanson et al., 1994; Ammann
 126 et al., 2013; Ammann et al., 2003; Knopf et al., 2005; Li and Knopf, 2021; Schwartz, 1986). In the
 127 resistor model approach, the uptake of a gas species with reaction at the surface and in the bulk is
 128 described by the following or equivalent equations (Pöschl et al., 2007):

$$129 \quad \frac{1}{\gamma} = \frac{1}{\alpha_s} + \frac{1}{\Gamma_s + \frac{1}{\frac{1}{\Gamma_{sb}} + \frac{1}{\Gamma_b}}} . \quad (2)$$

130 Here, γ is the uptake coefficient, defined as the overall loss rate from the gas phase normalized to
 131 the gas kinetic collision rate, and α_s is the surface accommodation coefficient, which represents
 132 the probability for a gas molecule colliding with the surface to be accommodated at the surface for
 133 period longer than the duration of an elastic scattering process (Pöschl et al., 2007). This parameter
 134 thus represents the adsorption rate normalized to the gas kinetic collision rate. The term Γ_s
 135 represents the normalized loss rate due to surface reaction, Γ_{sb} is the normalized rate of surface to
 136 bulk transfer, and Γ_b is the normalized loss rate in the bulk-phase induced by solubility, diffusion
 137 and reaction (Hanson et al., 1994; Ammann et al., 2013; Crowley et al., 2013; Kolb et al., 2010;
 138 Ammann and Pöschl, 2007; Pöschl et al., 2007; Wilson et al., 2022; Shiraiwa and Pöschl, 2021).
 139 By virtue of the coupled nature of the involved elementary processes, the desorption rate
 140 coefficient can influence the rates of all other surface and bulk processes involving this species,
 141 i.e., k_{des} can influence Γ_s , Γ_{sb} , and Γ_b (Pöschl et al., 2007). For example, the terms Γ_s , Γ_{sb} and Γ_b
 142 governed by the competition between desorption and surface reaction, between desorption and
 143 surface to bulk transfer, or between desorption and surface to bulk transfer coupled to reaction and
 144 diffusion, respectively, are inversely proportional to k_{des} and can be expressed as follows:

$$145 \quad \Gamma_s = \alpha_s \frac{k_s}{k_{des}} , \quad (3)$$

$$146 \quad \Gamma_{sb} = \alpha_s \frac{k_{sb}}{k_{des}} , \quad (4)$$

$$\Gamma_b = \alpha_s \frac{k_{sb} \sqrt{k_b D_b}}{k_{des} k_{bs}} . \quad (5)$$

Here, k_s is a first-order rate coefficient of chemical reaction at the surface; k_{sb} is a first-order rate coefficient for the transfer of molecules from the surface into the bulk (solvation); k_b is a first-order rate coefficient of chemical reaction in the bulk; D_b is the diffusion coefficient of the trace gas in the bulk; k_{bs} is a first-order rate coefficient for the transfer of molecules from the bulk to the surface. Even though the rate coefficients for these elementary processes are independent of k_{des} , the overall normalized rates of Γ_s , Γ_{sb} , and Γ_b are. Similarly, the overall rate of transfer of a gas molecule into the bulk of a liquid or (semi)solid particle (independent of whether diffusion and reaction therein contributes to loss) also depends on k_{des} and can be expressed by the bulk accommodation coefficient, α_b (Pöschl et al., 2007; Edwards et al., 2022):

$$\alpha_b = \alpha_s \frac{k_{sb}}{k_{sb} + k_s + k_{des}} . \quad (6)$$

Hence, the desorption rate coefficient is a critical parameter influencing all processes overall rates involved in the uptake of a gas species by condensed matter (Li and Knopf, 2021).

The role of reversible adsorption and desorption has been addressed in many studies of gas uptake and heterogeneous chemistry in particular for the decoupling of mass transport and chemical reaction (Kolb et al., 1995; Hanson and Ravishankara, 1991; Kolb et al., 2010; Ammann et al., 2013; Crowley et al., 2013; Pöschl and Shiraiwa, 2015; Tabazadeh et al., 1994; Peter, 1997; Carslaw et al., 1997; Hanson et al., 1994; Hanson and Lovejoy, 1995). More recently, kinetic multilayer model analyses of measured uptake coefficients for OH radicals on levoglucosan substrates (Arangio et al., 2015) and the heterogeneous reaction of ozone with shikimic acid (Berkemeier et al., 2016; Steimer et al., 2015) and oleic acid aerosol (Berkemeier et al., 2021) demonstrated the complex dependency of the reactive uptake coefficient on the elementary steps, such as surface accommodation, desorption, surface reaction and bulk diffusion by virtue of Eq.

170 (3-5). The range of experimental conditions was not sufficient to constrain the associated
171 coefficients unambiguously. To determine a best estimate for the surface reaction rate coefficient,
172 it was thus necessary to assume a realistic value for α_s and τ_{des} derived from molecular dynamics
173 simulations (Vieceli et al., 2005; Von Domaros et al., 2020). *Li and Knopf* (2021) made use of the
174 temperature-dependent measurement of OH uptake to decouple τ_{des} from surface reactivity. The
175 intimate coupling of adsorption and desorption with other multiphase processes has also been
176 discussed in the context of many other reaction systems. Ground-breaking work driving much of
177 the developments of the kinetic concepts introduced above was directed at halogen activation on
178 stratospheric aerosol and polar stratospheric clouds (Tabazadeh et al., 1994; Peter, 1997; Carslaw
179 et al., 1997; Hanson et al., 1994; Hanson and Lovejoy, 1995). ~~These~~ Others include the uptake of
180 SO₂ into sulfuric acid (Jayne et al., 1990; Ammann and Pöschl, 2007), adsorption of acetone on
181 ice and HNO₃ on mineral dust (Bartels-Rausch et al., 2005; Vlasenko et al., 2009; Cwiertny et al.,
182 2008; Usher et al., 2003), ozonolysis in liquid, viscous, and solid particles (Knopf et al., 2005;
183 Berkemeier et al., 2016; Steimer et al., 2015; Shiraiwa et al., 2011a; Hearn and Smith, 2007; Pöschl
184 et al., 2001; Shiraiwa et al., 2009; Zhou et al., 2013; Kahan et al., 2006; Kwamena et al., 2004;
185 Mu et al., 2018; Knopf et al., 2011; Willis and Wilson, 2022), and gas-particle partitioning of SOA
186 (Shiraiwa et al., 2013a; Ingram et al., 2021; Schervish and Shiraiwa, 2023). Accordingly, the
187 design and interpretation of heterogeneous and multiphase reaction rate measurements should
188 include a careful assessment whether reversible adsorption is an important or even rate-limiting
189 step, whereby the applicable kinetic regime, may vary with reaction time and conditions
190 (Berkemeier et al., 2013; Berkemeier et al., 2016; Shiraiwa et al., 2014; Ingram et al., 2021; Willis
191 and Wilson, 2022). Hence, desorption lifetimes and related activation energies are important for
192 describing the interaction of gas phase and condensed phase species.

193 To address and elucidate these issues, the remainder of this article is structured as follows: In
194 Section 2, we discuss the molecular interactions underlying adsorption and desorption, and we
195 outline the relevant thermodynamic and kinetic equations and parameters. In Section 3, we compile
196 and present a comprehensive set of desorption energies and thermodynamic parameters for
197 environmentally and atmospherically relevant gas species and substrates. In Section 4, we evaluate
198 the role of the desorption energy in reactive and non-reactive gas uptake by solid and liquid
199 substrates considering characteristic tropospheric temperatures by exploratory kinetic flux model
200 simulations. In Section 5, we develop and present a simplified parameterization for estimating E_{des}^0
201 based on the gas species' polarizability and oxygen to carbon (*O:C*) ratio. Section 6 outlines the
202 role of E_{des}^0 in selected atmospheric implications including the formation and properties of viscous
203 secondary organic aerosol (SOA). We conclude the document with a summary and open questions.

204

205 **2. Thermodynamic Relations**

206 A detailed discussion of the microscopic and thermodynamic treatments of adsorption and
207 desorption and implications for uncertainties in E_{des}^0 is given in *Knopf and Ammann (2021)*. Here
208 we provide the key relationships and concepts needed to follow our assumptions when applying
209 literature obtained E_{des}^0 values for derivation of a parameterization.

210 Typically, the adsorption rate is a measure of the amount of gas molecules that adsorb on the
211 surface as a consequence of gas kinetic collisions. As mentioned above, in the atmospheric
212 sciences this is often expressed with the surface accommodation coefficient α_s (Kolb et al., 2010),
213 operationally defined as the probability that a gas kinetic collision leads to adsorption. The
214 adsorbed molecules may be considered an ideal 2D gas, meaning that the molecules have
215 equilibrated with the surface in terms of the degrees of freedom perpendicular to the surface but

216 may still retain some kinetic energy parallel to the surface. Alternatively, the adsorbed molecules
 217 may be considered an ideal 2D lattice gas, where the degrees of freedom in the horizontal plane
 218 are restricted to vibrations. Also, other models describing intermediate situations have been
 219 suggested (Savara et al., 2009; Campbell et al., 2016; Kisliuk, 1957). Here, we use α_s to describe
 220 the rate of adsorption into either adsorbed state. The term thermal accommodation coefficient, α_t ,
 221 is commonly used for the case where the adsorbed molecule is fully thermally equilibrated with
 222 the substrate, thus close to the case of the ideal 2D lattice gas. Adsorption can be considered a non-
 223 activated process, though in presence of an energy barrier, adsorption has to be treated as an
 224 activated process (Knopf and Ammann, 2021). The corresponding energy barrier directly impacts
 225 α_s (Knopf and Ammann, 2021). In contrast, desorption is always treated as an activated process,
 226 even in the absence of an energy barrier. The explicit treatment of an additional energy barrier
 227 when deriving adsorption and desorption rates is given in *Knopf and Ammann (2021)*. Here we
 228 solely consider E_{des}^0 as reported in the literature, independent of whether an additional activation
 229 barrier was included in the analysis. As discussed below, the choice of adsorbate model and
 230 standard state will impact the value and uncertainties in E_{des}^0 (Knopf and Ammann, 2021; Savara,
 231 2013; Campbell et al., 2016).

232 Adsorption proceeds spontaneously and this implies an exergonic process with the
 233 thermodynamic condition (Bolis, 2013):

$$234 \quad \Delta G_{\text{ads}}^0 = \Delta H_{\text{ads}}^0 - T\Delta S_{\text{ads}}^0 < 0, \quad (6)$$

235 where ΔG_{ads}^0 represents the standard Gibbs free energy change of adsorption, ΔH_{ads}^0 is the
 236 standard enthalpy change of adsorption (in this case negatively defined), ΔS_{ads}^0 is the standard
 237 entropy change of adsorption, and T is temperature. Adsorption of a gas on a substrate results in
 238 an increase of order, thus, $\Delta S_{\text{ads}}^0 < 0$. This is because the degrees of freedom of the adsorbed

239 molecules are more constrained than in the gas phase. Often, the adsorbed molecule may be
240 considered a 2D ideal gas, a 2D ideal lattice gas, or an ideal hindered translator on the surface,
241 with the motion perpendicular to the surface strongly constrained but with varying freedom parallel
242 to the surface (Hill, 1986; Campbell et al., 2016; Savara et al., 2009; Sprowl et al., 2016). Since
243 $\Delta S_{\text{ads}}^0 < 0$, the change in enthalpy ΔH_{ads}^0 has to be negative. The adsorption enthalpy is determined
244 by the binding energy of a gas on the surface, thus on the molecular interactions between gas
245 species and substrates, including hydrogen bonds and van der Waals forces (Poe et al., 1988;
246 Valsaraj and Thibodeaux, 1988; Valsaraj, 1988a, b; Goss and Eisenreich, 1995b; Goss, 1993,
247 1994b; Valsaraj, 1994; Valsaraj et al., 1993). The van der Waals forces comprise London
248 dispersion forces between instantaneously induced dipoles, Debye forces between permanent and
249 induced dipoles, and Keesom forces between permanent dipoles (Iupac, 1997). For organic
250 molecules, the strength of both van der Waals and hydrogen bonds depends on the polarity of
251 functional groups and commonly follows the order (Jeffrey, 1997; Jeffrey and Saenger, 1991;
252 Vinogradov and Linnell, 1971):

253 Amide > Acid > Alcohol > Ketone \approx Aldehyde > Amine > Ester > Ether > Alkane .

254 Table 1 gives an overview of intermolecular forces active among functional groups present in
255 typical gas- and condensed-phase atmospheric species. While all molecules exhibit van der Waals
256 forces, their thermodynamic properties are largely determined by the number and type of hydrogen
257 bonds they can form. The presence of charged groups, e.g., due to a dipole moment, can
258 significantly increase binding energy. The hydrogen bond strength in liquid water is around 10-19
259 kJ mol⁻¹ (Hakem et al., 2007), and with a few exceptions, usually involving fluorine, the energies
260 associated with hydrogen bonding are typically less than 20-25 kJ mol⁻¹ per hydrogen bond
261 (Steiner, 2002; Jeffrey, 1997; Jeffrey and Saenger, 1991; Brini et al., 2017; Iupac, 1997).

262 The complexity of the interaction between adsorbate and substrate can go beyond the 2D ideal
263 gas, 2D ideal lattice gas, and hindered translator model depending on how physisorption and
264 chemisorption are considered. For example, the Kisliuk precursor mechanism allows for more
265 complex configurations of the adsorbate that could include adsorbate-adsorbate interactions
266 (Kisliuk, 1957; Tully, 1994; Campbell et al., 2016; Kisliuk, 1958). Hence, the overall adsorbate-
267 substrate binding energy may involve contributions from adsorbate-surface as well as adsorbate-
268 adsorbate interactions (see e.g. Meyer et al., 2001). Moreover, the binding energy may vary
269 between different types of adsorption sites co-existing on real surfaces, depending on the
270 morphology and chemical heterogeneities of the substrate (Kolasinski, 2012). In view of the
271 complex mixture of substances present in the atmosphere, such effects and variations are not
272 explicitly resolved in this study. Instead, we assume that the energetics of reversible adsorption on
273 atmospheric surfaces can be approximated by effective average values characterizing the binding
274 energy to the substrate. The assumption of reversible adsorption has been crucial in studies of gas
275 uptake and heterogeneous or multiphase chemical reactions when decoupling mass transport and
276 chemical reaction (Kolb et al., 2010; Hanson and Ravishankara, 1991; Ammann et al., 2013;
277 Crowley et al., 2013; Pöschl and Shiraiwa, 2015; Li and Knopf, 2021). The assumption of
278 reversible adsorption directly leads to $\Delta H_{\text{ads}}^0 = -\Delta H_{\text{des}}^0$ and $\Delta S_{\text{ads}}^0 = -\Delta S_{\text{des}}^0$, where ΔH_{des}^0 and
279 ΔS_{des}^0 represent the changes in the desorption enthalpy and entropy, respectively.

280 The free energy change is the driving force for desorption from the thermodynamic point of
281 view. The Frenkel equation, given by Eq. (1), is usually applied to describe the kinetics of
282 desorption. By itself it does not differentiate between physisorption and chemisorption. For the
283 description and understanding of atmospheric heterogeneous and multiphase kinetics, it is useful
284 to treat chemisorption as a chemical reaction following physisorption (Pöschl et al., 2007; Hanson

285 et al., 1994; George and Abbatt, 2010), as expressed in Eqs. (2) to (5). We note that the energy
 286 range of 50 kJ mol⁻¹ mentioned above to distinguish between physisorption and chemisorption is
 287 not necessarily appropriate, if chemisorption is reflecting the fact that chemical bonds are formed
 288 or disrupted. Large molecules may undergo a multitude of van der Waals and hydrogen bonds
 289 adding up to large interaction energies, which would still be considered physisorption. As outlined
 290 above, for these cases we regard the adsorption process to be reversible.

291 *Knopf and Ammann* (2021) have provided the thermodynamic and microscopic equations, the
 292 latter based on conventional transition state (TS) theory, that are implicitly included in the Frenkel
 293 equation, while accounting for the choice of standard states. For example, for the case of a 2D
 294 ideal gas as adsorbate model, the desorption rate expressed in thermodynamic quantities is

$$295 \quad k_{\text{des}} = \kappa \left(\frac{k_{\text{B}}T}{h} \right) \frac{(N_{\text{TS}}/\mathcal{A})^0}{(N_{\text{ads}}/\mathcal{A})^0} e^{-\Delta G_{\text{des}}^0/RT} = \kappa \left(\frac{k_{\text{B}}T}{h} \right) e^{-\Delta G_{\text{des}}^0/RT}, \quad (7)$$

296 where κ is a transmission coefficient giving the probability with which an activated complex
 297 proceeds to desorption (Kolasinski, 2012), k_{B} is the Boltzmann constant, and h is the Planck
 298 constant. Furthermore, we assume the standard concentration of molecules in the TS, $(N_{\text{TS}}/\mathcal{A})^0$,
 299 is equal to the standard concentration of adsorbed molecules, $(N_{\text{ads}}/\mathcal{A})^0$, i.e., $\frac{(N_{\text{TS}}/\mathcal{A})^0}{(N_{\text{ads}}/\mathcal{A})^0} = 1$.

300 In microscopic quantities, k_{des} is derived as

$$301 \quad k_{\text{des}} = \kappa \left(\frac{k_{\text{B}}T}{h} \right) \left(\frac{q_{\text{TS}}^{0'}}{q_{\text{ads}}^0} \right) \frac{(N_{\text{TS}}/\mathcal{A})^0}{(N_{\text{ads}}/\mathcal{A})^0} e^{-\frac{(E_{\text{des}}^0)}{RT}}, \quad (8)$$

302 where $q_{\text{TS}}^{0'}$ and q_{ads}^0 are the standard partition functions for the TS and adsorbate, respectively,
 303 evaluated using standard molar volume and area. Equations (7) and (8) clearly demonstrate the
 304 importance of the choice of standard state when comparing measured k_{des} and evaluated E_{des}^0 .

305 Looking at the equations for k_{des} allows to derive the pre-exponential factor of the Frenkel
 306 equation as (Knopf and Ammann, 2021)

307
$$A_{\text{des}} = \kappa \left(\frac{k_{\text{B}}T}{h} \right) \left(\frac{q'_{\text{TS}}}{q_{\text{ads}}} \right) = \kappa \left(\frac{k_{\text{B}}T}{h} \right) \frac{(N_{\text{TS}}/\mathcal{A})^0}{(N_{\text{ads}}/\mathcal{A})^0} e^{\Delta S_{\text{des}}^0/R}, \quad (9)$$

308 where q'_{TS} and $q_{\text{ads},2\text{D}}$ are the partition functions for the TS and adsorbate, respectively. The
 309 microscopic interpretation of A_{des} shows that A_{des} depends on temperature and the choice of
 310 adsorbate model, expressed as partition functions. The thermodynamic interpretation of A_{des}
 311 demonstrates its dependency on standard concentrations and the change in entropy when desorbing
 312 from the substrate surface into the activated TS.

313 We can now interpret A_{des} for the case of a 2D ideal gas adsorbate model. If we assume $\kappa \approx 1$,
 314 and adsorbate and TS are 2D ideal gases with similar degrees of freedom (neglecting vibrations),
 315 i.e., $\frac{q'_{\text{TS}}}{q_{\text{ads}}} = 1$, then we obtain $A_{\text{des}} \approx \frac{k_{\text{B}}T}{h} = 6 \times 10^{12} \approx 10^{13} \text{ s}^{-1}$ at room temperature (298 K).
 316 This is the commonly applied value for the pre-exponential factor. In this case, Eq. (9)
 317 demonstrates that the change in ΔS_{des}^0 must be negligible. However, significant deviations from
 318 this benchmark factor can occur. For example, if going from the adsorbate state to the activated
 319 TS coincides with $\Delta S_{\text{des}}^0 > 0$, and thus $\frac{q'_{\text{TS}}}{q_{\text{ads}}} > 1$, implying more degrees of freedom in the TS, then
 320 $A_{\text{des}} > 10^{13} \text{ s}^{-1}$. In contrast, if the TS is more constrained, e.g., only a limited number of molecular
 321 orientations are allowed, then $\Delta S_{\text{des}}^0 < 0$, and thus $\frac{q'_{\text{TS}}}{q_{\text{ads}}} < 1$, then $A_{\text{des}} < 10^{13} \text{ s}^{-1}$. A similar analysis
 322 has been provided for the 2D ideal lattice gas adsorbate model (Knopf and Ammann, 2021). A_{des}
 323 varies between 180 and 300 K for a 2D ideal gas and 2D ideal lattice gas adsorbate model by about
 324 a factor of 2 and 3, respectively, indicating minor temperature effects (Knopf and Ammann, 2021).
 325 However, A_{des} can differ by about 3 orders of magnitude between the 2D ideal gas and 2D ideal
 326 lattice gas adsorbate models.

327 Experimental studies usually yield pre-exponential factors in the range between 1×10^{11} to
 328 $1 \times 10^{12} \text{ s}^{-1}$ for smaller molecules such as methane and $1 \times 10^{13} \text{ s}^{-1}$ for larger alkanes (Fichthorn and

329 Miron, 2002). For large adsorbates, A_{des} can be several orders of magnitude larger (Fichthorn and
330 Miron, 2002). For example, adsorption of benzene and toluene by graphite surfaces exhibit A_{des}
331 of about 10^{15} and 10^{19} s^{-1} , respectively (Ulbricht et al., 2006). In general, the larger the adsorbate
332 molecule, the larger A_{des} (Ulbricht et al., 2006).

333 Nevertheless, for this study and the compilation of literature data of E_{des}^0 , we have assumed a
334 constant pre-exponential factor $A_{\text{des}} = 1 \times 10^{13} \text{ s}^{-1}$, being aware of the underlying assumptions
335 discussed above. We justify this approach by noting that our aim is to derive E_{des}^0 estimates for
336 complex substrate systems, including multicomponent and multiphase aerosol particles, which will
337 impose additional uncertainties in E_{des}^0 . Due to the involvement of entropic contributions to the
338 pre-exponential factor, experimentally derived A_{des} values often contain not well-documented
339 implicit standard state assumptions (related to experimental surface to volume ratios) (Donaldson
340 et al., 2012a; Campbell et al., 2016; Savara, 2013) and thus carry more uncertainty than the E_{des}^0
341 obtained from the slope of temperature dependent data.

342 Figure 1 displays the dependency of τ_{des} on E_{des}^0 and temperature using the Eq. (1). As
343 illustrated in Fig. 1a, the temperature dependency of τ_{des} increases with increasing E_{des}^0 .
344 Calculations have been performed with $A_{\text{des}} = 10^{13} \text{ s}^{-1}$, while the shading represents the
345 application of A_{des} being one order of magnitude greater or smaller, thereby covering the typical
346 temperature dependency of A_{des} . Clearly, temperature can significantly increase the residence time
347 of a molecule on the substrate surface, by several orders of magnitude, thereby, potentially,
348 allowing different reaction pathways. It is also evident that uncertainties in A_{des} directly translate
349 into corresponding uncertainties in τ_{des} . Hence, assuming $A_{\text{des}} = 10^{13} \text{ s}^{-1}$ in the analysis of
350 literature data will yield uncertainties in E_{des}^0 values. For example, one order of magnitude
351 uncertainty in A_{des} , changes E_{des}^0 by $\sim 4\text{-}6 \text{ kJ mol}^{-1}$ over a temperature range of 210 to 300 K.

352 Conversely, an uncertainty of E_{des}^0 by 5 kJ mol^{-1} imposes an uncertainty in τ_{des} of about a factor
353 of ~ 7 - 17 for a similar temperature range. These interdependencies are further outlined in Fig. 1b
354 showing typical τ_{des} for given temperatures and E_{des}^0 , again derived assuming $A_{\text{des}} = 10^{13} \text{ s}^{-1}$.
355 This discussion implies an uncertainty in our E_{des}^0 values of about $\pm 5 \text{ kJ mol}^{-1}$. However, as
356 outlined in detail in *Knopf and Ammann (2021)*, additional uncertainties in E_{des}^0 can arise when
357 the appropriate adsorbate model is not known and if the surface coverage of the adsorbate is
358 uncertain. For example, for a given τ_{des} , E_{des}^0 can differ by 10 - 15 kJ mol^{-1} when assuming either
359 a 2D ideal gas or 2D ideal lattice gas adsorbate model. If a surface is assumed to be pristine but
360 actual coverage is about 20% , E_{des}^0 may be uncertain by 10 - 20 kJ mol^{-1} . In summary, literature
361 E_{des}^0 values applied in this analysis, assuming a conservative estimate, may be uncertain by up to
362 $\sim \pm 15 \text{ kJ mol}^{-1}$.

363 In the formulation of the kinetic and thermodynamic concepts and expressions, we have not
364 made an explicit assumption about the physical state of the condensed phase - solid, liquid,
365 crystalline or amorphous. Lattice gas statistics can be applied generally in different dimensions
366 and has been used for liquids, sorption of ions to proteins or polymer wires (Hill, 1986). In spite
367 of the simplifying assumptions, we use the equations summarized above and derived in more detail
368 in (Knopf and Ammann, 2021) for all substrates, including liquids. This is straightforward for
369 poorly soluble gases. For soluble gases, however, the full thermochemical cycle also involves the
370 dissolved state (Donaldson, 1999). We also note that the system free energy change upon
371 adsorption of a gas on a liquid manifests in a surface tension change, with the Gibbs adsorption
372 isotherm relating the surface tension change to surface excess (Kolasinski, 2012; Donaldson,
373 1999). The manifestation of the change in surface tension convolutes the complex response of
374 structure and dynamics at a liquid interface to an adsorbing molecule (Brini et al., 2017).

375 Depending on the polarity of the adsorbate, the structural features of the interface may then also
376 deviate significantly from that of an adsorbate on a solid surface, as exemplified in recent theory
377 work by Cruzeiro et al. (2022) and Galib and Limmer (2021) for the interaction of N_2O_5 with
378 water.

379 **3. Compilation of Desorption Energies for Solid and Liquid Substrates**

380 To derive a parameterization of E_{des}^0 applicable to typical gas-aerosol particle systems,
381 literature values of E_{des}^0 reflecting typical atmospheric constituents or serving as aerosol surrogates
382 have been compiled. If available, E_{des}^0 reflects values derived from lowest surface coverage,
383 preferentially below one monolayer. Tables A1-A7, A8, and A9-A15 provide thermodynamic and
384 physicochemical literature values for gas-to-solid, gas-to-ice, and gas-to-liquid substrate
385 interactions, respectively. For derivation of E_{des}^0 and τ_{des} values, we use Eq. (1) and assume
386 $A_{des} = 10^{13} \text{ s}^{-1}$, if not otherwise noted. We assume the temperature effect on A_{des} (proportional
387 to T , see Eq. (9)) and changes in the desorption entropy to be negligible compared to the Arrhenius
388 factor (Eq. (8)). The tables include the parameters E_{des}^0 , τ_{des} , and for the gas species the molar
389 mass (M), enthalpy of vaporization (ΔH_{vap}), polarizability (α), dipole moment (μ), $O:C$, and
390 enthalpy of solvation (ΔH_{sol}). Lastly, the dielectric constant or relative permittivity of the substrate
391 (ϵ_r) is given. E_{des}^0 values are obtained from different experimental techniques and theoretical
392 studies described briefly below.

393

394 **3.1 Experimental and theoretical techniques yielding desorption energies**

395 Temperature programmed desorption (TPD), sometimes also termed thermal desorption
396 spectroscopy (TDS), is an experimental technique where the flux of desorbing molecules is
397 observed as the surface temperature is increased. TDS can yield coverages, activation energies,

398 and pre-exponential factors for desorption (Ulbricht et al., 2006). Thermal gravimetry with
399 differential scanning calorimetry (TG-DSC) determines the amount and rate (velocity) of change
400 in the mass of a sample as a function of temperature or time in a controlled atmosphere in addition
401 to thermophysical and thermoplastic properties derived by DSC (Giraudet et al., 2006). In general,
402 if heats of adsorption are measured experimentally by, e.g., calorimetric methods, the accurate
403 thermodynamic definitions have to be applied since heat is not a state function (Bolis, 2013). In
404 Knudsen cells and diffusion tubes coupled to mass spectrometric detection (KN) the rate of
405 molecules desorbing from a substrate can be selectively measured (Caloz et al., 1997; Koch and
406 Rossi, 1998b; Tolbert et al., 1987; Alcalá-Jornod et al., 2000). Scattering experiments of molecular
407 beams (MB) are applied to directly measure desorption from and adsorption of gas species to solid
408 or liquid substrates (Thomson et al., 2011; Morris et al., 2000; Nathanson et al., 1996). While
409 straightforward in use and interpretation for solid surfaces in high vacuum, the developments
410 around using MB techniques for atmospherically relevant volatile liquids is experimentally
411 challenging and also data interpretation with respect to desorption is less straightforward
412 (Nathanson, 2004; Ringeisen et al., 2002b; Morris et al., 2000; Klassen et al., 1997; Nathanson et
413 al., 1996; Gao and Nathanson, 2022), as discussed below. Inverse gas chromatography (IGC)
414 applies the solid of interest as the chromatographic sorbent (stationary phase) and yields sorption
415 coefficients of gas species (Mader et al., 1997). Vacuum microbalance (VM) determines the
416 change in weight due to adsorbed gases (Rouquerol and Davy, 1978; Thomas and Williams, 1965).
417 The desorption rate can be determined by measuring the time evolution of the adsorbed phase by
418 using diffuse reflectance infrared Fourier transform spectroscopy (DRIFT), while the gas phase is
419 monitored by selected-ion flow-tube mass spectrometry (SIFT-MS) and long path transmission
420 Fourier transform infrared spectroscopy (FTIR) (Romanias et al., 2016). Since measurement of the

421 desorption rate requires pressures in the molecular flow regime, this is only straightforward for
422 low vapor pressure materials, such as mineral dust or dry salts. For high vapor pressure materials
423 (aqueous or organic liquids and ice) or materials featuring complex microstructure (mineral dust,
424 soot), complications arise from the convolutions of pore space (Woodill et al., 2013; Keyser et al.,
425 1991), bulk liquid diffusion (Koop et al., 2011b; Pöschl et al., 2007), gas phase diffusion (Knopf
426 et al., 2015; Fuchs and Sutugin, 1971; Fuchs, 1964; Seinfeld and Pandis, 1998; Pöschl et al., 2007)
427 and other coupled processes, making the determination of desorption life time an indirect and often
428 difficult task. Kinetic uptake (KU) experiments operated in the molecular flow regime can yield
429 estimates of species' surface residence times (Alcala-Jornod et al., 2000; Koch and Rossi, 1998a;
430 Koch et al., 1997). KU experiments using laminar flow tube reactors can also yield estimates of
431 the residence time of adsorbed species via determination of the Langmuir equilibrium constant
432 (Pöschl et al., 2001; Von Hessberg et al., 2008; Slade and Knopf, 2013). Vibrational spectroscopy
433 (VS) is used to study the interaction of molecules with, e.g., ice surfaces, by examining the shifted
434 dangling hydrogen bond of ice in presence of an adsorbed molecule (Silva and Devlin, 1994).
435 Surface tension (ST) measurements of adsorbing gases on liquid substrates can yield directly the
436 thermodynamic parameters describing adsorption (Hauxwell and Ottewill, 1968; Donaldson,
437 1999), and the molecular level relationship between surface excess and surface coverage can be
438 assessed by direct spectroscopy (Lee et al., 2016).

439 IGC derives sorption coefficients which can yield estimates of E_{des}^0 via the van't Hoff equation
440 (Goss and Eisenreich, 1996). For experimental TPD and TDS desorption data analysis usually the
441 Redhead equation (Redhead, 1962) is applied that considers the heating rate and gas species
442 surface coverage. k_{des} derived from DRIFT studies yields τ_{des} which allows derivation of E_{des}^0
443 according to Eq. (1), with similar constraints with respect to effusion times from packed powder

444 samples (Woodill et al., 2013; Keyser et al., 1991). MB methods allow to uniquely differentiate
445 thermal desorption of molecules from those undergoing elastic or inelastic scattering, or from those
446 undergoing exchange with the bulk and/or reaction. For solid surfaces the interpretation is
447 straightforward, and corresponding desorption lifetimes can directly be observed. For liquid
448 surfaces, this is less straightforward, since the trajectory of a desorbing molecule may involve
449 diffusion into and out of the near-surface bulk layers (Faust et al., 2013), so that the ‘surface
450 residence time’ is not strictly a true desorption lifetime. Equilibrium measurements of surface
451 tension as a function of partial pressure of the trace gas allows to determine ΔG_{ads}^0 and ΔH_{ads}^0 , if
452 the latter is assumed to be independent of temperature (Donaldson, 1999).

453 The choice of standard states can impact data interpretation. Standard free energies of formation
454 are typically referenced to 1 bar or 1 mol L⁻¹ (at 298 K) (Donaldson et al., 2012a). Commonly it
455 can be assumed that standard enthalpy values are not strongly dependent on the choice of standard
456 state, because the dependence of enthalpy on pressure is weak (Donaldson et al., 2012a). However,
457 the standard entropies of phase transfer will depend on the choice of the standard-state (Donaldson
458 et al., 2012a; Knopf and Ammann, 2021; Campbell et al., 2016; Savara, 2013). Further
459 complications arise when choosing standard states for different adsorbate-surface interactions
460 (Campbell et al., 2016). This can impact standard state surface concentrations, equilibrium
461 constants and rate constants, and renders the adsorbate chemical potential dependent on surface
462 coverage (Campbell et al., 2016; Savara, 2013).

463 Molecular dynamics (MD) simulations can provide estimates of the residence time of gas
464 species at a surface or interface (Vieceli et al., 2005; Von Domaros et al., 2020). MD simulations
465 can yield residence times at the interface or substrate surface and as such an estimate of τ_{des} . Then,
466 for given A_{des} and temperature, E_{des}^0 can be estimated using Eq. (1). Density functional theory

467 (DFT) represents a computational quantum mechanical modelling method to compute the
468 electronic structure of matter (Meng et al., 2004). Monte Carlo (MC) methods based on
469 computational algorithms rely on repeated random sampling to obtain numerical results (Remorov
470 and Bardwell, 2005). Grand canonical Monte Carlo (GCMC) simulations account for density
471 fluctuations at fixed volume and temperature and represents the preferred choice for the
472 investigation of interfacial phenomena (Croteau et al., 2009; Collignon et al., 2005). A theoretical
473 approach to the description of the electronic structure of molecules adsorbed on solid surfaces and
474 surface reactions is the embedded cluster theory (ECT) (Whitten, 1993). This allows ab initio
475 calculations of molecular properties of the lattice-adsorbate system. The dipped adcluster model
476 (DAM) is applied to study chemisorption and surface reactions in which an adcluster (admolecule
477 + cluster) is dipped onto the electron bath of a solid metal (Nakatsuji, 1987). This treatment allows
478 to derive adsorption energies (Hu and Nakatsuji, 1999).

479

480 **3.2 Atmospherically Relevant Gas-Substrate Systems**

481 **Gas Adsorption by Solid Substrates.** Gas adsorption and desorption is important when
482 describing the reactivity between trace gases and solid interfaces in terms of removal rates and
483 gas-particle partitioning (Kolb et al., 2010; Pöschl et al., 2007). It also constitutes a significant
484 removal process of gaseous organic compounds by partitioning between gas and solid phases
485 (Goss and Eisenreich, 1996, 1995a; Goss, 1993). Mineral dust particles are the most abundant
486 aerosol particles globally by mass, providing ample solid surface area for adsorption of gaseous
487 species (Usher et al., 2003; Tang et al., 2016). Atmospheric soot particles also represent a solid
488 surface which allows for multiphase chemistry involving adsorption and reaction of atmospheric
489 oxidants (Pöschl et al., 2001; Shiraiwa et al., 2009; Kaiser et al., 2011; Springmann et al., 2009),

490 though soot can be complex consisting of solid graphite structures coated by organic carbon, the
491 latter being amorphous or soft in nature (Bond et al., 2013; China et al., 2013; Cappa et al., 2012).
492 Also, amorphous solid organic particles (Virtanen et al., 2010; Koop et al., 2011b; Shiraiwa et al.,
493 2017a) provide solid substrates that serve as adsorption and reactive sites for trace gas species
494 (Knopf et al., 2018; Slade et al., 2017; Slade and Knopf, 2014, 2013; Houle et al., 2018; Hearn
495 and Smith, 2007; Lakey et al., 2016; Berkemeier et al., 2016; Steimer et al., 2015; Shiraiwa et al.,
496 2011a; Li and Knopf, 2021; Li et al., 2020).

497 In the atmosphere, adsorbing trace gases including oxidants, radicals, and VOCs compete with
498 adsorbing water for substrate surface sites. A mineral dust surface is usually hydroxylated and
499 covered by a monolayer of water at about 20-30% relative humidity (Usher et al., 2003; Tang et
500 al., 2016; Goss, 1994a). Adsorption of water by mineral dust is also crucial for our understanding
501 of the ability of dust particles to serve as CCN (Tang et al., 2016) and INPs (Kanji et al., 2017;
502 Knopf et al., 2018; Knopf and Koop, 2006; Hoose and Möhler, 2012; Knopf and Alpert, 2023).
503 Since water vapor is abundant in our environment, adsorption of a reactive or non-reactive gas
504 species will likely always proceed in competition with co-adsorbing water molecules (Kaiser et
505 al., 2011; Springmann et al., 2009). Reactive uptake of O₃ and OH radicals by insoluble organic
506 aerosol surfaces has been shown to decrease as humidity increases, following a Langmuir-
507 Hinshelwood mechanism, where water vapor co-adsorbs and competes for surface sites (Pöschl et
508 al., 2001; Slade and Knopf, 2014). Condensation of water may lead to dissolution of soluble gas
509 species and coating material on top of solid substrates, e.g., present as an aqueous organic coating
510 on soot (Charnawskas et al., 2017). Those cases should then be considered as a solid substrate
511 covered by a liquid layer and adsorption or uptake processes should be treated as proceeding on a
512 liquid substrate. Tables A1-A7 present a compilation of E_{des}^0 and other molecular parameters for

513 a selection of atmospherically relevant reactive and non-reactive trace gases interacting with
514 various solid substrates serving as surrogates of aerosol particles.

515

516 **Gas Adsorption by Ice.** Ice is among the most abundant solid materials on the Earth's surface.
517 Roughly 50% of the northern hemisphere landmass is covered by ice and snow in winter (Bartels-
518 Rausch, 2013). Adsorption and desorption of trace gases on ice impact gas-phase chemistry in the
519 stratosphere and upper troposphere (Solomon, 1999; Borrmann et al., 1996; Voigt et al., 2006;
520 Huthwelker et al., 2006), snow chemistry and boundary layer gas-phase chemistry over perennial
521 and permanent snowpacks and gas-phase chemistry above sea-ice (Bartels-Rausch et al., 2014;
522 Artiglia et al., 2017; Raso et al., 2017; George et al., 2015; McNeill et al., 2012; Abbatt et al., 2012;
523 Jeong et al., 2022; Mcnamara et al., 2021). Partitioning of gases to ice in polar and high-alpine
524 snow also result in signals in ice cores used to reconstruct past climates and environmental
525 conditions (Vega et al., 2015). In comparison to other solid materials, ice is a high-temperature
526 material existing in the environment at temperatures relatively close to its melting point. As in
527 other molecular solids this leads to surface premelting and thus a disordered interface, also referred
528 to as quasi-liquid layer, the properties of which are a matter of ongoing debate (Bartels-Rausch et
529 al., 2014; Asakawa et al., 2016; Cho et al., 2002; Slater and Michaelides, 2019). Since this layer
530 is the interface with which adsorbing gases interact, the mutual interplay between the properties
531 of the disordered interface and the nature of the interaction of gases have spurred speculations
532 about whether it should be treated as a thin aqueous solution layer or a purely solid surface. Recent
533 spectroscopic evidence indicates that soluble gases form solvation shells similar as in liquid water
534 without, however, modifying the remaining ice structure significantly (Bartels-Rausch et al.,
535 2017). Thus under typical atmospherically relevant conditions with low coverages of volatile

536 gases, the surface remains dominated by the properties of ice. A template for this may be the case
537 of HCl adsorption on ice (Huthwelker et al., 2006), for which singly hydrogen bonded HCl is
538 adsorbed at the outermost surface (Kong et al., 2017), while upon hydration and dissociation,
539 chloride enters deeper into the interface (Zimmermann et al., 2016; McNeill et al., 2007; McNeill
540 et al., 2006). This is in accord with a low desorption energy and thus low coverage with molecular
541 HCl (Table A8). This behavior can mask the weak temperature dependence of the total coverage
542 by HCl (molecular and dissociated). Similar conclusions come from MB experiments, e.g., with
543 NO_y compounds, where the desorption kinetics are characterized directly (Lejonthun et al., 2014).
544 An exception may be the case of H₂O itself, where the MB experiments may not have been able
545 to resolve singly hydrogen bonded H₂O desorbing, but only completely hydrated ones desorbing
546 more slowly (Kong et al., 2014b; Kong et al., 2014a). Therefore, adsorption on ice may well be
547 considered as adsorption within the simplified scheme adopted in this work even for very soluble
548 and more straightforwardly for less soluble molecules. Table A8 summarizes the thermodynamic
549 literature data on gas species adsorption by ice substrates applied in this study.

550

551 **Gas Adsorption by Water and Aqueous Solutions.** Liquid water and aqueous solutions are a
552 dominant form of condensed matter in the environment including aerosol particles, clouds, or
553 ocean surfaces. In aerosol particles, aqueous solutions may range from dilute solutions at very high
554 humidity and at or close to the point of activation into a cloud droplet to very concentrated
555 supersaturated solutions at low relative humidity. High solute strength solutions may yield highly
556 viscous, semi-solid and glassy particle phase states occurring throughout the atmosphere (Shiraiwa
557 et al., 2017a; Koop et al., 2011b; Mikhailov et al., 2009; Zobrist et al., 2008; Klassen et al., 1998).
558 Decreasing bulk diffusivity in these viscous phases increases the relative importance of the

559 desorption lifetime as exchange with the bulk is retarded (Behr et al., 2009; Knox and Phillips,
560 1998; Li and Knopf, 2021) (see Eq. (4)).

561 The notion that adsorbed molecules on liquid surfaces represent a distinct feature comes from
562 both spectroscopic and kinetic evidence. MB experiments of HCl on deuterated sulfuric acid
563 clearly identified collision-, adsorption-, and desorption trajectories (Behr et al., 2001; Morris et
564 al., 2000; Gao and Nathanson, 2022), as a direct and unique manifestation of Langmuir's view of
565 adsorption (Langmuir, 1918). The time the HCl molecule spends on the surface is directly related
566 to E_{des}^0 and A_{des} . In other cases studied by the MB technique, the picosecond scale hydrogen bond
567 exchange dynamics and fast diffusion (nanoseconds – microseconds for diffusion into and out of
568 depths of several nanometers) prevented unambiguous separation of pure desorption from
569 trajectories including entry into the liquid (Ringeisen et al., 2002a, b; Brastad et al., 2009; Faust
570 and Nathanson, 2016; Faust et al., 2016; Faust et al., 2013). A comparable situation as for HCl has
571 been documented through the MB technique for N_2O_5 (Shaloski et al., 2017). Later high-level
572 theory work established the interaction of this important trace gas with the hydrogen bonding
573 network of water that then subsequently controls hydrolysis (Cruzeiro et al., 2022; Galib and
574 Limmer, 2021). Similar conclusions about adsorption – desorption trajectories in the case of
575 $\text{H}_2\text{O}(\text{g})$ on liquid water may be drawn from different isotope exchange kinetics for HDO with H_2O
576 and H_2^{18}O with H_2O that require different degrees of hydration on the water surface (Davidovits
577 et al., 2011, 2006). The suggestion that a distinct population of H_2O molecules exists that is singly
578 hydrogen bonded at the liquid water surface comes from detailed interpretation of IR spectra in
579 line with theory (Devlin et al., 2000). The high vapor pressure of environmentally relevant liquids
580 and other difficulties (including those related to fast exchange with the bulk liquid) prevent direct
581 determination of desorption kinetics for many relevant trace gas – substrate pairs. In spite of this

582 situation, we suggest to apply the same concept of converting desorption energies (derived from
583 partitioning or chromatographic methods) into desorption lifetimes as for solid surfaces.

584 The fact that molecules at the aqueous solution or liquid water – air interface experience a
585 different environment than in the bulk liquid is straightforward. The density drops over molecular
586 length scales and the hydrogen bond dynamics and orientation in water and aqueous solutions on
587 average lead to a strongly asymmetric environment at the interface (Brini et al., 2017; Ahmed et
588 al., 2021; Hao et al., 2022). The extension of the interface depends on the type of solutes and
589 adsorbates present, as molecules with larger hydrophobic moieties or when charges are present at
590 the adsorbate interacting with solute ions, which may establish a larger interfacial thickness (Brini
591 et al., 2017; Zhao et al., 2020). The asymmetric environment at the interface leads to specific
592 molecular interaction options (as described above) and in turn to specific binding energies as result
593 of these. Changes to the equilibrium surface tension of aqueous solutions in response to adsorption
594 of gases is the consequence of the changes in the surface free energy. Its temperature dependence
595 is reflecting the energy gain as a result of the sum of these interactions. Tables A9 to A15 are a
596 compilation of E_{des}^0 for a range of inorganic and organic trace gases on pure water or on aqueous
597 solutions. The simplest case $\text{H}_2\text{O}(\text{g})$ on $\text{H}_2\text{O}(\text{l})$, exhibits a single hydrogen bond and a
598 corresponding low E_{des}^0 value. Among the given families of species, interaction energies scale with
599 molar mass or the degree of substitution with functional groups that alter the amount of weak or
600 strong molecular interactions. The degree of substitution may be represented by the dipole moment
601 (μ) and $O:C$ for organic molecules as outlined in the discussion of parameterized E_{des}^0 . The
602 presence of hydrophilic functional groups with strong hydrogen bonding interaction options leads
603 to correspondingly larger E_{des}^0 . Since these groups also interact with the hydrogen bonding

604 network of water, these interactions are sensitive to the presence of other solutes or, especially,
 605 ions (Demou and Donaldson, 2002; Lee et al., 2019; Ohrwall et al., 2015; Ekholm et al., 2018).

606

607 **4. Impact of Desorption Lifetime on Gas Uptake**

608 To assess the impact of τ_{des} on multiphase chemical kinetics, the kinetic multi-layer models of
 609 aerosol surface and bulk chemistry (K2-SURF, KM-SUB) are applied (Shiraiwa et al., 2010;
 610 Shiraiwa et al., 2009). These models are based on the PRA framework (Ammann and Pöschl, 2007;
 611 Pöschl et al., 2007) and describe the gas-particle interface by implementation of several model
 612 compartments and molecular layers in which species can undergo mass transport and chemical
 613 reactions. Here, the compartments included are: gas phase, near-surface gas phase, sorption layer,
 614 quasi-static surface layer, and a number of bulk layers.

615 Gas-phase diffusion of a species X from the gas phase to the near-surface gas-phase surrounding
 616 the particle is treated by the net flux of gas-phase diffusion:

$$617 \quad J_{\text{g,X}} = 2\pi(d_p + 2\lambda D_g)([X]_{\text{g}} - [X]_{\text{gs}}), \quad (10)$$

618 where d_p is the particle diameter, λ is the mean free path, D_g is the gas diffusivity and $[X]_{\text{g}}$ and
 619 $[X]_{\text{gs}}$ are concentrations of X in the gas and near-surface gas phases, respectively (Pöschl et al.,
 620 2007; Knopf et al., 2015; Li et al., 2018). The mass balance and rate equation for X in the near-
 621 surface gas phase can be described as:

$$622 \quad \frac{d[X]_{\text{gs}}}{dt} = \frac{J_{\text{g,X}} - (J_{\text{ads,X}} - J_{\text{des,X}})A_s}{V_{\text{gs}}}, \quad (11)$$

623 where A_s is the particle surface area and V_{gs} is the volume of the near-surface gas phase. $J_{\text{des,X}}$ is
 624 the desorption flux defined as $J_{\text{des,X}} = k_{\text{des,X}}[X]_{\text{s}} = \tau_{\text{des,X}}^{-1}[X]_{\text{s}}$. $J_{\text{ads,X}}$ is the adsorption flux defined

625 as $J_{\text{ads},X} = \alpha_{s,X} J_{\text{coll},X}$, where $\alpha_{s,X}$ represents the surface accommodation coefficient, and the
 626 collision flux is defined as $J_{\text{coll},X} = \frac{1}{4} \omega_X [X]_{\text{gs}}$ with ω_X being the mean thermal velocity of X.

627 The surface-layer reaction (SLR), involving only the adsorbed species, X(s), or components of
 628 the quasi-static layer, Y(ss), such as $X(s) + Y(ss) \rightarrow \text{products}$, is described by the second-order
 629 rate coefficient k_{SLR} . The surface reaction rate is described as $L_s = k_{\text{SLR}} [X]_s [Y]_{\text{ss}}$. The mass
 630 balance and rate equations for X in the near-surface gas phase and at the surface can be described
 631 as below:

$$632 \frac{d[X]_s}{dt} = J_{\text{ads},X} - J_{\text{des},X} - L_s - J_{s,b,X} + J_{b,s,X}, \quad (12)$$

633 where $J_{s,b,X}$ and $J_{b,s,X}$ are the fluxes from the surface to the near-surface bulk and from the near-
 634 surface bulk to the surface of X, respectively ($J_{s,b,X} = J_{b,s,X} = 0$ in the absence of bulk diffusion),
 635 and treated as a function of the bulk diffusion coefficient. The reactive uptake coefficient, γ , is
 636 usually the experimentally accessible parameter and the one used in atmospheric modeling studies.
 637 γ of a gas species X is defined as

$$638 \gamma_X = \frac{J_{\text{ads},X} - J_{\text{des},X}}{J_{\text{coll},X}}. \quad (13)$$

639
 640 **Simulation of reactive gas uptake by solid substrates.** We apply the kinetic double-layer model
 641 of aerosol surface chemistry (K2-SURF; (Shiraiwa et al., 2009)) to investigate the sensitivity of γ
 642 to the desorption lifetime for a solid substrate. The surface reaction of an adsorbed species X with
 643 condensed species Y is considered, while surface-bulk exchange and bulk diffusion and reaction
 644 are not considered for simplicity. The α_s on an adsorbate-free substrate is assumed to be one for
 645 all simulations. Figure 2 shows the dependence of γ on τ_{des} and k_{SLR} at constant temperature. γ
 646 values represent steady-state values. Higher k_{SLR} leads to higher γ at fixed τ_{des} due to faster

647 surface reaction rates. At fixed k_{SLR} , longer τ_{des} leads to higher surface concentrations of X, and
648 consequently to higher surface reaction rates and γ . In turn, with sufficiently long residence times
649 of the adsorbed gas species, low k_{SLR} can still lead to high values of γ . It is evident that different
650 pairs of τ_{des} and k_{SLR} can yield the same γ value. Furthermore, when k_{SLR} is known, uncertainties
651 in τ_{des} can result in large differences in γ . This exercise demonstrates that experimentally derived
652 γ values do not sufficiently constrain the heterogeneous reaction process to yield unambiguous
653 τ_{des} and k_{SLR} values, unless a significant parameter space is covered by the experiment to constrain
654 them individually. For instance, at large enough gas phase partial pressure the surface gets
655 saturated (fully covered by the adsorbate), which leads to decoupling of τ_{des} and k_{SLR} (Knopf et
656 al., 2011; Artiglia et al., 2017; Berkemeier et al., 2016; Steimer et al., 2015). However, this is often
657 not possible due to technical constraints. Therefore, constraining τ_{des} by application of E_{des}^0 , or
658 best estimates of E_{des}^0 , can significantly improve our molecular understanding of the underlying
659 processes in multiphase chemical kinetics and support the development of parameterizations for
660 modelling purposes.

661 Figure 3 displays the temperature dependence of γ with E_{des}^0 of 30 – 50 kJ mol⁻¹. The pre-
662 exponential frequency factor A_{des} was set to 10¹³ s⁻¹ and k_{SLR} was set to (a) 10⁻¹² and (b) 10⁻⁹ cm²
663 s⁻¹. Temperature dependence of k_{SLR} was not considered in these simulations to evaluate only the
664 effects of temperature-dependent τ_{des} on γ . The modeling results suggest that γ depends strongly
665 on temperature, where lower temperatures yield higher γ values. This is because lower
666 temperatures lead to longer τ_{des} and hence higher surface concentrations of X and reaction rates.
667 Generally, γ is more temperature-dependent at higher values of E_{des}^0 . However, if E_{des}^0 is close to
668 values typical for chemisorption (~50 kJ mol⁻¹), γ is close to 1 in this calculation. Further away
669 from this special case and natural cap of $\gamma = 1$, γ increases by about two orders of magnitude over

670 a temperature range of 80 K. These modeling results indicate that extrapolating multiphase
671 chemical kinetics acquired at room temperature to lower temperatures, can result in significantly
672 different reactive uptake coefficients. Clearly, a detailed understanding of the molecular processes
673 is necessary when applying multiphase reaction kinetics to environmental and atmospheric
674 conditions.

675 Even though the above simulations clearly suggest potentially large effects of the temperature
676 dependence of τ_{des} on γ , surface reaction rate coefficients are also temperature dependent which
677 in turn affect γ as well (Li and Knopf, 2021; Li et al., 2020). To further investigate the role of
678 temperature on heterogeneous reaction kinetics, we apply the K2-SURF model to heterogeneous
679 reactions between O_3 and polycyclic aromatic hydrocarbons (PAHs) adsorbed on soot. This
680 reaction proceeds with a multi-step Langmuir-Hinshelwood mechanism that includes I) O_3
681 physisorption, II) decomposition of O_3 into long-lived reactive oxygen intermediates (ROIs, O
682 atoms), and III) reactions of O atoms with PAHs (Shiraiwa et al., 2011b):

686 The activation energy for physisorbed O_3 to dissociated into chemisorbed O ($E_{\text{a,pc}}$) is $\sim 40 \text{ kJ mol}^{-1}$
687 and the activation energy for O reacting to oxidation products (E_{ox}) is $\sim 80 \text{ kJ mol}^{-1}$ (Berkemeier
688 et al., 2016; Shiraiwa et al., 2011b). Temperature dependence of the reaction rate coefficients of
689 reactions II and III are considered using an Arrhenius equation. We examine the response of this
690 reaction system to changes in initial E_{des}^0 of O_3 (reaction I) and temperature.

691 Figure 4 shows the results of such simulations. Higher E_{des}^0 yields higher surface concentrations
692 of physisorbed O_3 , and hence higher concentrations of O and reaction rates, yielding higher γ

693 values. γ decreases as temperature decreases, which is in contrast to above sensitivity studies
694 shown in Fig. 3. This is because the overall temperature dependency of the gas uptake is mostly
695 determined by the temperature dependency of the rate-limiting reaction III and also influenced by
696 thermally-activated chemical reaction II. Although physisorbed O_3 molecules can reside
697 significantly longer on the PAH surface at lower temperatures, the decrease in the formation rate
698 of ROIs and subsequent oxidation reaction rate govern γ , suggesting lower γ values at lower
699 temperatures.

700 Clearly, E_{des}^0 and activation energies for chemical reactions are crucial parameters to predict
701 multiphase chemical kinetic processes under tropospheric conditions. Conducting temperature-
702 dependent reactive uptake experiments of known reaction systems can be used to determine
703 coupled desorption lifetimes and reaction rates (e.g., Kerbrat et al., 2010; Li and Knopf, 2021).
704 For example, *Li and Knopf* (2021) measured the reactive uptake of OH radicals by triacontane for
705 temperatures between 213 and 293 K. By having a temperature-dependent multiphase kinetics data
706 set, E_{des}^0 and k_{SLR} could be decoupled and individually assessed.

707
708 **Non-reactive gas uptake into liquids.** To demonstrate the effect of τ_{des} on the equilibration
709 timescale of non-reactive gas uptake by a liquid substrate, the kinetic multi-layer model for aerosol
710 surface and bulk chemistry (KM-SUB) (Shiraiwa et al., 2010) was applied (Fig. 5). We simulate
711 non-reactive uptake of species X with a constant gas-phase concentration of 1 ppb into a particle
712 with 100 nm diameter that initially contains no amount of X. The Henry's law constant of X was
713 set to be $1 \times 10^{-5} \text{ mol cm}^{-3} \text{ atm}^{-1}$ at 298 K and its temperature dependence was considered using the
714 van't Hoff equation with a solvation enthalpy of 20 kJ mol^{-1} ; these values are chosen to be
715 comparable with ozone solvation into water (Sander, 2015, 2023). The temperature dependence of

716 the Henry's law constant is shown in Fig. S1. The particle is assumed to be liquid with a
717 temperature-dependent bulk diffusion coefficient following the parameterization of Zobrist *et al.*
718 (2011) for pure water, which varies from $2 \times 10^{-5} - 2 \times 10^{-6} \text{ cm}^2 \text{ s}^{-1}$ in this temperature range. E_{des}^0
719 values in the range of $10 - 80 \text{ kJ mol}^{-1}$ were used, and the temperature dependence of τ_{des} was
720 considered using the Frenkel equation (see Eq. (1) and Fig. 1). Here, X can be regarded as a small
721 molecule with moderate water solubility such as ozone for the simulations at low E_{des}^0 , or a
722 carboxylic acid with similar water solubility (e.g., nonanoic acid) for the simulations at high E_{des}^0 .
723 The equilibration time is defined as the time after which the surface and particle bulk
724 concentrations deviate by less than a factor of $1/e$ from their equilibrium or steady-state value.

725 The simulations show that equilibration times can vary over many orders of magnitude in the
726 investigated range of E_{des}^0 (Fig. 5). For $E_{\text{des}}^0 < 30 \text{ kJ mol}^{-1}$, the timescales of surface equilibration
727 (black solid lines) are shorter than the timescale of bulk equilibration (blue dashed lines). The
728 convergence of the blue lines at low E_{des}^0 ($< 30 \text{ kJ mol}^{-1}$) reflects the kinetic limitation of gas-
729 particle equilibration by diffusion inside the particle bulk ($2 \times 10^{-7} \text{ s}^{-1}$; (Shiraiwa *et al.*, 2011a)). At
730 higher E_{des}^0 , the increase of desorption lifetime leads to the increase of the equilibration times, as
731 a larger amount of X is needed to saturate the surface; in fact, at $E_{\text{des}}^0 \geq 15 \text{ kJ mol}^{-1}$, the majority
732 of molecules reside on the surface and the partitioning is governed by the surface processes in this
733 simulation.

734 In the range of E_{des}^0 around 40 to 60 kJ mol^{-1} , surface and bulk equilibration times coincide, as
735 the simulated 100 nm particles are well-mixed and non-reactive uptake is limited by interfacial
736 transport from the gas phase. The flattening and convergence of the black lines at $E_{\text{des}}^0 > 60 \text{ kJ}$
737 mol^{-1} reflects the kinetic limitation of gas-particle equilibration by interfacial transport (surface
738 adsorption and surface-bulk exchange) if the surface gets fully covered by the adsorbate. The bulk

739 equilibration (blue lines) and thus also the overall gas-particle equilibration time still increase for
740 $E_{\text{des}}^0 > 60 \text{ kJ mol}^{-1}$ with decreasing temperature, because interfacial transport is slowed by the high
741 surface propensity of X and its full surface coverage. Note that the slowing of bulk equilibration
742 time as a consequence of sorption layer coverage is a direct consequence of using a Langmuir
743 adsorption model. In case of multilayer adsorption and bulk condensation, especially at high E_{des}^0 ,
744 results may differ, which will be explored in follow-up studies (see also Sect. “Gas-particle
745 Partitioning of Secondary Organic Aerosol”). Also note that the increased surface propensity of X
746 with increasing E_{des}^0 is not a general rule, but a consequence of the fixed Henry’s law solubility
747 coefficient in this sensitivity study.

748 The calculations for Fig. 5 represent an open system in which the gas-phase concentration of X
749 is held constant. *Wilson et al. (2021)* investigated equilibration timescales for gas uptake of PAHs
750 on soot surfaces in the closed system, i.e., where a fixed amount of X is distributed between the
751 gas and particulate phases. In that study, equilibration timescales were either controlled by the
752 adsorption or by the desorption process, depending on whether the particle surface was under- or
753 oversaturated with X at the start of the model simulations, respectively. Temperature strongly
754 influenced equilibration timescales in the desorption-controlled regime, whereas particle number
755 concentrations influenced adsorption-controlled systems. Note that in the presence of chemical
756 reactions in the gas phase or on the surface, the partitioning equilibrium can be perturbed and adopt
757 a quasi-stationary state that differs from thermodynamic equilibrium.

758 For reactions occurring in liquids, the same features apply as for the case of surface reactions on
759 solids, i.e., the temperature dependence of an activated reaction may counteract the temperature
760 dependencies of desorption and solubility, e.g., for the reactions on sulfuric acid aerosol of HCl
761 with HONO (Longfellow et al., 1998; Ammann et al., 2013) or with ClONO₂ (Shi et al., 2001).

762 These cold and viscous sulfuric acid aerosols, but also viscous aqueous organic aerosols are also
763 at the same time high solute strength systems. The situation then is very complex since viscosity
764 is modulated by temperature and humidity, thereby impacting diffusion and salting out effects, and
765 thus, ultimately, solubility and kinetics (Edebeli et al., 2019; Li and Knopf, 2021; Li and Shiraiwa,
766 2019).

767

768 **5. Derivation of a Parameterization of the Desorption Energy**

769 Thermodynamic and chemical parameters given in Tables A1-A15 provide the basis to derive
770 E_{des}^0 estimates for application in multiphase chemical kinetics involving atmospheric gas species
771 and aerosol particles. This analysis includes over 500 gas species-substrate systems. As discussed
772 above, we note the underlying caveats in this analysis. The pre-exponential factor is set to 10^{13} s^{-1} .
773 ¹. The dependence of E_{des}^0 on adsorbate model and surface coverage is neglected. Thus, a highly
774 accurate prediction of E_{des}^0 is not possible. However, the goal here is to provide a best estimate of
775 E_{des}^0 in agreement with this training data set (Tables A1-A15) to enable improved analyses of
776 environmental multiphase chemical kinetics under the wide range of thermodynamic conditions
777 encountered in the Earth's environment. Furthermore, it would be desirable to predict E_{des}^0 from
778 commonly measured and accessible parameters, e.g., derived by mass spectroscopy, such as molar
779 mass, molecular structure, and oxidation state.

780 Following our previous discussion on the intermolecular bonding between adsorbate and
781 substrate, gas species polarizability, α , should serve as predictor of E_{des}^0 . Larger α should, in
782 general, coincide with an increase in E_{des}^0 . The oxidation state of an organic gas species,
783 represented in a simplified way by the ratio $O:C$, reflects the number of oxygenated functional
784 groups, typically monitored by mass spectrometry (Isaacman-Vanwertz et al., 2018). An increase

785 in the gas species' oxidation state should also yield an increase in E_{des}^0 . Figure 6 displays a
 786 multilinear regression analysis using all available data including solid, ice, and liquid substrates
 787 (Tables A1-A15) to derive a relationship between E_{des}^0 , α , and $O:C$. Figure S2 depicts the same
 788 data in more detail as two separate plots. Figure 6 indicates that E_{des}^0 increases with increasing α
 789 and $O:C$, as one would expect from considerations of intermolecular bonding discussed above.
 790 This is also corroborated by a principal component analysis given in Fig. S3, showing significant
 791 correlation between E_{des}^0 and α . The regression analysis yields the following model (with an $R^2 =$
 792 0.559 and a root mean squared error (RMSE) = 25.4):

$$793 \quad E_{\text{des}}^0(\alpha, O:C) = 25.895 + 2.330\alpha + 12.367(O:C) , \quad (14)$$

794 where E_{des}^0 is in units kJ mol^{-1} and α is in units 10^{-24} cm^3 .

795 Figure 7 shows α as a function of molar mass and $O:C \leq 1$. Note that the few data for the three
 796 gas species with $O:C \geq 1$, namely CO_2 (Table A3), formic acid (Table A7), and, peroxyacetyl
 797 nitrate, PAN (Table A8) are colored as $O:C = 1$ for better visibility of the overall training set.
 798 Figure 6 shows the few data points for $O:C > 1$. The data show a strong linear correlation between
 799 α and M , where $O:C$ appears to play a less significant role. This can be understood by realizing
 800 that a carbon atom in a molecule contributes three times more to α than an oxygen atom (Bosque
 801 and Sales, 2002), discussed in more detail below. Hence, the number of methylene groups can
 802 dominate α for larger molecules. Thus, the polarizability can be described, applying regression
 803 analysis, as a linear function of molar mass ($R^2 = 0.952$ and $\text{RMSE} = 2.765$):

$$804 \quad \alpha(M) = -0.837 + 0.128M , \quad (15)$$

805 where M is in units g mol^{-1} . The linear regression is shown as a red line in Fig. 7.

806 We can now combine Eqs. (14) and (15) to obtain a parameterization to calculate E_{des}^0 from
 807 knowledge of the gas species' molar mass and $O:C$:

$$E_{\text{des}}^0(M, O:C) = 25.895 + 2.330(-0.837 + 0.128M) + 12.367(O:C) . \quad (16)$$

Figure 8 shows E_{des}^0 values derived from Eq. (16) using M and $O:C$ values given by the training datasets as input. Similarly to Fig. 7, we have color-coded $O:C$ for values up to one for better data visibility. Figure S4 shows E_{des}^0 values derived from the training data set separated by different substrate types corroborating the correlation displayed in Fig. 8. Figure S5 shows E_{des}^0 values derived from Eq. (16) using arbitrary M and $O:C$ values. For application of inorganic gas species with $C = 0$, $O:C$ should be set to zero. E_{des}^0 shows a linear relationship with M where deviation from linearity is only found at $M < 250 \text{ g mol}^{-1}$. Figure 8B demonstrates that gas species with larger $O:C$ show larger E_{des}^0 . To understand this trend in the data, we have to address the role of the gas species' dipole moment and substrate in the derivation of the E_{des}^0 values. Equation (16) provides estimates of E_{des}^0 without specifically addressing substrate properties. As discussed, its dependency solely on M and $O:C$ is advantageous for application to complex gas species-particle composition data. Considering the underlying uncertainties due to unknown applied standard states, absorbate model, and assumed pre-factor, this parameterization is accurate within those limits. However, one would expect that gas species' μ and the substrate's ϵ_r impact E_{des}^0 .

We recommend application of this parameterization (Eq. (16)) for gas species with $O:C \lesssim 1$. Due to the few data points at $O:C \gtrsim 1$, E_{des}^0 could be significantly under- or overestimated in this range. For example, for CO_2 (Table A3), tabulated $E_{\text{des}}^0 = 16.4 \text{ kJ mol}^{-1}$, while the parameterization yields 61.8 kJ mol^{-1} . In the case of formic acid (Table A7), the tabulated $E_{\text{des}}^0 = 94.6 \text{ kJ mol}^{-1}$, while the parameterization yields 62.4 kJ mol^{-1} . Hence, when applying Eq. (16) to gas species with $O:C \gtrsim 1$, considering additional information or constraints is recommended.

For our data set, the principal component analysis in Fig. S3 indicates no strong correlation between ϵ_r and E_{des}^0 . Fig. 9 corroborates the negligible dependence of E_{des}^0 on ϵ_r . However, one

831 would expect that greater μ , α , and ϵ_r result in larger E_{des}^0 due to enhanced molecular interactions.
832 The derivation of our parameterization exploited the strong dependency of E_{des}^0 on α . We suggest
833 that the underlying reason for this dependency is the competing effects of μ and α on E_{des}^0 as
834 outlined below.

835 Small molecules with polar groups can exert significant dipole moments while the polarizability
836 is still small. As depicted in Fig. S6, smaller molecules exert greater μ while $O:C$ values are high
837 and α is low (see also Fig. 7). Note that alkanes and PAHs in the data set, following common
838 convention, have zero dipole moments. Gas species with greater μ may interact more strongly with
839 polarizable substrates expressed by ϵ_r , yielding larger E_{des}^0 . However, as the gas molecules become
840 larger, their α increases, e.g., by the addition of methylene groups (Bosque and Sales, 2002),
841 thereby dominating over the impact of μ on E_{des}^0 . Figure S2 supports this trend where molecules
842 with largest α have low $O:C$ and small μ . Hence, this data set yields a negative correlation between
843 μ and α . As a consequence, for larger molecules the role of the molecule's μ interacting with the
844 substrate becomes less important. Thus, in a way, the range of available desorption data could be
845 responsible for the negligible correlation between E_{des}^0 and substrate ϵ_r (Fig. 9). In other words,
846 polarizability α , which is strongest for molecules with small μ and low $O:C$, compensates and
847 dominates the impact of the dipole moment on E_{des}^0 and, in turn, renders the substrate of less
848 importance for parameterizing E_{des}^0 . This is also evident in Fig. 10, where the scatter of
849 parameterization-derived E_{des}^0 values is largest for molecules with lower M and lower α . We can
850 attribute the scatter in E_{des}^0 at lower M to the competing contributions of the gas species' μ , here
851 accounted by $O:C$ and α . These may be the reasons why E_{des}^0 can be reasonably parameterized
852 from our data set without accounting for the substrate's ϵ_r and gas species' μ . Though, we would

853 expect with more available data, the role of gas species' μ and substrate's ε_r to likely be resolved
854 in a parameterization.

855 Considering the significant number of data and omission of substrate specific properties in the
856 parameterization, the scatter in E_{des}^0 is not very large. This suggests that this parameterization can
857 serve as a reasonable first estimate of E_{des}^0 for a complex environmental substrate such as an
858 aerosol particle. We would expect that with increasing number of desorption data that include
859 larger molecules with larger $O:C$ or μ and applied known standard states and adsorbate models,
860 the scatter in E_{des}^0 at lower molar masses can be resolved.

861

862 **Relationship Between Desorption Energy and Enthalpy of Vaporization.** To examine the
863 relationship between E_{des}^0 and ΔH_{vap} , we have plotted the data given in supplemental tables (not
864 the parameterized values) separated for the different substrate types in Fig. 11. Our data supports
865 a positive correlation between E_{des}^0 and ΔH_{vap} , where E_{des}^0 for most instances is larger than ΔH_{vap} .
866 The role of $O:C$ in the relationship between E_{des}^0 and ΔH_{vap} is not clearly identifiable for the cases
867 that include all, solid, and ice substrates data. However, for liquid substrates, the data suggest that
868 for given ΔH_{vap} , larger $O:C$ yields larger E_{des}^0 . Figure S7 provides a linear regression model for
869 the case of liquid substrates. As shown above, larger $O:C$ correlates with a larger μ , which may
870 exert a greater impact on E_{des}^0 in the case of a liquid substrate. In fact, the interaction strength at
871 the surface often exceeds the enthalpy of condensation between gas and its condensed liquid for
872 the same species family, e.g., in the case of methyl-substituted benzenes (Raja et al., 2002; Bruant
873 and Conklin, 2002), but also for other species like alcohols, acids, amines and ketones (Mmereki
874 et al., 2000) and alkanes (Goss, 2009) and halogenated alkanes (Bruant and Conklin, 2001). This
875 indicates that the aqueous solution – air interface allows for a two-dimensional environment in

876 which the intermolecular interactions are as important as in the **bulk** condensed phase of the
877 adsorbate alone (Valsaraj, 1988a, 2009).

878

879 **Relationship Between Desorption Energy and Enthalpy of Solvation for Aqueous**

880 **Substrates.** To examine the relationship between E_{des}^0 and ΔH_{solv} , we have plotted the data for
881 liquid substrates, consisting mostly of water and few aqueous solutions (Tables A9 to A15) in Fig.
882 12. Despite the scatter in the data, a positive correlation between E_{des}^0 and ΔH_{solv} can be identified.
883 The data falls symmetrically around the 1:1 line, indicating no strong bias. In the case of liquid
884 substrates, the correlation between E_{des}^0 and ΔH_{solv} is comparable to that observed between E_{des}^0
885 and ΔH_{vap} (Fig. 11c). Figure S8 provides a linear regression model for the data shown in Fig. 12.

886 The relationship between E_{des}^0 and ΔH_{solv} shown in Fig. 12 can be understood in the following
887 way. For large non-polar molecules, the free energy cost of entering the aqueous solution is mostly
888 driven by enthalpic changes, because hydrogen bonds need to be disrupted to form a cavity around
889 the molecule (Kronberg, 2016; Valsaraj, 1988a; Brini et al., 2017). The surface energy in that
890 cavity is then driven by the surface energy of pure water and the hydrophobic interactions with the
891 solute (Chandler, 2005). This is then somewhat similar to the situation when the same molecule is
892 adsorbed at the aqueous solution – air interface. Thus, for the larger non-polar molecules, the
893 contribution of the enthalpy of cavity formation can be identified as a dominating factor of the
894 solvation process, which in turn depends on the intermolecular strength between adsorbing
895 molecule and liquid. This, hence, can explain the correlation between E_{des}^0 and ΔH_{solv} for the case
896 of the non-polar molecules.

897 For small non-polar molecules, the transfer to the aqueous phase is mostly entropy-driven,
898 because the hydrogen bonds do not need to be disrupted but need to reorganize around the solute

899 (Kronberg, 2016; Shinoda, 1992, 1977; Hvidt, 1983; Brini et al., 2017). Polar molecules would be
900 comparable to ions, but also in this case, the size and charge distribution determine the cost of
901 solvation through the number and strength of hydrogen bonds to water, which lead to a correlation
902 of and ΔH_{solv} with the number of hydrophilic groups. The latter also determine E_{des}^0 (i.e., $O:C$
903 correlates with μ). Among the small organic molecules contained in Fig. 12, with the increasing
904 presence of hydrophilic functional groups, the larger $O:C$ ratios lead to larger E_{des}^0 . For these
905 reasons, the relationship between E_{des}^0 and ΔH_{solv} shown in Fig. 12 supports the specific and
906 physical interaction model at the aqueous solution – air interface mentioned above: E_{des}^0 scales
907 with the magnitude of hydrophobic interactions for non-polar molecules and with the presence of
908 hydrophilic functional groups (i.e., $O:C$ correlates with μ) for polar molecules, and thus the
909 correlation with ΔH_{solv} is a logical consequence.

910 Note that since both E_{des}^0 and ΔH_{solv} are correlated, and are mostly independent of temperature
911 (Hildebrand and Scott, 1964) within the idealized concept presented here, the temperature
912 dependence of τ_{des} may apparently dominate the temperature dependence of solvation when
913 $E_{\text{des}}^0 > \Delta H_{\text{solv}}$. This idea of parallel behavior of desorption and solvation is also supported by a
914 very recent experimental study that provides in situ measurements of the uptake of gas-phase water
915 into ionic liquids at the gas-liquid interface using ambient pressure X-ray photoelectron
916 spectroscopy (Broderick et al., 2019). These measurements indicate that, dependent on water mole
917 fraction and temperature, solvation is governed by similar thermodynamics as relevant for crossing
918 the gas-liquid interface during the mass-transfer process (Broderick et al., 2019). The positive
919 correlation between the E_{des}^0 and ΔH_{solv} values displayed in Fig. 12 supports this notion, ascribing
920 the molecular interactions controlling τ_{des} and solvation an important role in the molecular
921 understanding of gas-substrate interactions.

922

923 **6. Atmospheric Implications**

924 The discussion in the above sections demonstrated the importance of accurate knowledge of E_{des}^0
925 for the representation of multiphase chemical reactions across various environmental interfaces
926 and phase states including aerosol particles. Analyses of experimentally conducted multiphase
927 chemical kinetics studies as well modeling the detailed processes that lead to the physicochemical
928 transformation of particles and define their atmospheric fate will greatly benefit from improved
929 estimates of E_{des}^0 (Su et al., 2020; Zheng et al., 2020; Shiraiwa et al., 2017a; Shiraiwa et al., 2017b;
930 Shrivastava et al., 2017b; Shrivastava et al., 2017a; Li and Knopf, 2021; Kaiser et al., 2011;
931 Springmann et al., 2009; Mu et al., 2018; Hems et al., 2021; Laskin et al., 2015). Below we discuss
932 further relevant atmospheric chemistry processes that connect to and/or make use of E_{des}^0 including
933 gas-particle partitioning, secondary organic aerosol (SOA) formation, indoor air chemistry, and
934 glass transition of OA particles.

935 **Gas-Particle Partitioning of Secondary Organic Aerosol.** Organic aerosol is ubiquitous,
936 consists of numerous chemical species, and represents a large mass fraction (20–90%) of the total
937 submicron particles in the troposphere (Nizkorodov et al., 2011; Jimenez et al., 2009; Hallquist et
938 al., 2009; Kanakidou et al., 2005). The formation of SOA proceeds by complex pathways including
939 reaction and mass transport in the gas and condensed phases. The equilibration timescale for gas-
940 particle partitioning for SOA particles and particle-particle mixing of varying viscosity has been
941 evaluated (Shiraiwa and Seinfeld, 2012; Berkemeier et al., 2020; Schervish and Shiraiwa, 2023;
942 Li and Shiraiwa, 2019; Schervish et al., 2023). In some of those modeling studies a fixed $\tau_{\text{des}} =$
943 10^{-9} s, which corresponds to about $E_{\text{des}}^0 = 22$ kJ mol⁻¹ at 293 K, was applied. The simulation results
944 shown in Fig. 5, however, demonstrated that we can expect significant changes in condensed phase

945 equilibration times for gas-particle partitioning when E_{des}^0 and temperature change. Our tabulated
946 data suggests that oxygenated VOCs will exert larger E_{des}^0 and, as such, longer τ_{des} .

947 It has been shown that SOA oxidation products with a variety of functional groups fall into
948 molecular corridors characterized by a tight inverse correlation between volatility (or saturation
949 mass concentration, C_0) and molar mass as depicted in Fig. 13 (Li et al., 2016; Shiraiwa et al.,
950 2014). They are constrained by two boundary lines corresponding to the volatility of n-alkanes
951 C_nH_{2n+2} and sugar alcohols $C_nH_{2n+2}O_n$, which we now identify as “van der Waals” and “hydrogen-
952 bonding” dominated boundaries. This interpretation can be understood by the governing
953 intermolecular forces. For example, using the EVAPORATION model (Compernelle et al., 2011),
954 the vapor pressures for alkane, ketone, alcohol, and acid with a molecular weight of about 142 g
955 mol^{-1} at 298 K yield: $p^0(C_{10}H_{22}) = 1.73$ hPa, $p^0(H_7C_3C(O)C_5H_{11}) = 0.084$ hPa, $p^0(C_9H_{19}OH) =$
956 0.023 hPa, and $p^0(C_7H_{15}COOH) = 1.62 \times 10^{-3}$ hPa, respectively. The decrease of about three orders
957 of magnitude in the vapor pressure between the alkane and the carboxylic acid is mainly due to
958 two carboxylic acid molecules forming hydrogen bonds, resulting in a dimer. A highly-oxidized
959 amide having ketone and alcohol groups such as $N=CC(O)C(O)C(O)CO$ and $M = 149.146$ g mol^{-1}
960 has $p^0 = 8.93 \times 10^{-7}$ hPa. This is due to the fact that this molecule not only establishes the van der
961 Waals forces such as London dispersion and Keesom forces but also hydrogen bonding with three
962 hydrogen bond donors and multiple hydrogen bond acceptors. As can be seen in Fig. 13, the change
963 in C_0 derived from decane to C_0 of the highly-oxidized amide spans the identified molecular
964 corridor around $M = 145$ g mol^{-1} , indicating that the van der Waals forces and the number of
965 hydrogen bonds that can be established by a particular molecule may fundamentally describe the
966 volatility range of the organic species.

967 Keeping this approach in mind, we can ask: what are the extreme limits of the saturation mass
968 concentration? The smallest organic molecule is methane, only prone to London dispersion forces.
969 $p^0(\text{CH}_4) = 46000 \text{ hPa}$ with $\log_{10}(C_0) = 10.5$, which corresponds to the upper bound of the
970 molecular corridor. Ammonia (NH_3) has a similar molar mass as CH_4 but has lower vapor pressure,
971 because NH_3 can establish two hydrogen bonds. N_2O_5 does not form hydrogen bonds and locates
972 above the alkane line. The lower bound of the molecular corridor is mainly defined by the
973 molecule's permanent dipole moments and number of hydrogen bonds it can entertain. Clearly,
974 these attributes are likely to be found in larger and highly-oxidized compounds. Water constitutes
975 a peculiarity when looking at its position in the $C_0 - M$ framework depicted in Fig. 13. There is no
976 other molecule with this small size that can form four hydrogen bonds. Sulfuric acid (H_2SO_4) can
977 also form four hydrogen bonds and locates close to the lower bound of the molecular corridor. As
978 molecules become larger, there are steric hindrances that likely inhibit stronger intermolecular
979 bonding, whereas water with its small size is ideal. This reason may ultimately limit the lower
980 bound of the molecular corridor and thus the lowest volatilities experienced by OA species.

981 As we have discussed above, E_{des}^0 and ΔH_{vap} are positively correlated and E_{des}^0 in most cases
982 is larger than ΔH_{vap} (Fig. 11). Also, we found that gas species with higher $O:C$, and thus larger μ ,
983 exhibit larger E_{des}^0 values. This indicates that intermolecular interactions at the interface are as
984 important as in the condensed phase of the adsorbate alone (Valsaraj, 2009, 1988a). We expect
985 this also to hold for the case of SOA formation. It is generally observed that the composition of
986 the organic matrix, barring any mass-transport limitations, has little influence on the gas-particle
987 partitioning equilibrium (Donahue et al., 2012; Donahue et al., 2011). Oxygenated VOCs have
988 higher $O:C$ and larger μ . Saturation vapor pressure or volatility provides guidance in this regard
989 (Epstein et al., 2010), however, our study suggests that considering desorption, i.e., E_{des}^0 values,

990 can impact equilibrium times of gas-particle partitioning as outlined in the gas uptake multilayer
991 model simulations discussed in section 4.

992 Figure 13A shows that the compiled data sets fall within the $C_0 - M$ framework. In comparison,
993 Fig. 13B shows the distribution of SOA oxidation products (916 different species) in the $C_0 - M$
994 space evaluated previously by Shiraiwa *et al.* (2014). Since the gas species discussed in this work
995 cover a similar C_0 and M range as the SOA oxidation products, we can apply the parameterization
996 of E_{des}^0 to provide estimates of E_{des}^0 for gas species typically involved in SOA gas-particle
997 partitioning. This will allow a more detailed understanding and prediction of SOA formation, in
998 particular for temperatures typically encountered in the troposphere during transport.

999 We derive E_{des}^0 of SOA oxidation products by application of Eq. (14). Since we know the
1000 molecular structure of the SOA oxidation products, we can calculate polarizability using the
1001 equation provided by Bosque and Sales (2002), instead of using Eq. (15):

$$\begin{aligned} 1002 \quad \alpha = & 1.51\#C + 0.17\#H + 0.57\#O + 1.05\#N + 2.99\#S + 2.48\#P + 0.22\#F + \\ 1003 \quad & 2.16\#Cl + 3.29\#Br + 5.45\#I + 0.32, \end{aligned} \quad (20)$$

1004 where $\#C$, $\#H$, $\#O$, $\#N$, $\#S$, $\#P$, $\#F$, $\#Cl$, $\#Br$, and $\#I$ represent the respective numbers of atoms in
1005 the molecule.

1006 Figure 14 displays E_{des}^0 values for the molecular corridor data of SOA precursors gases and
1007 oxidation products from Fig. 13 as a function of molar mass and its dependence on $O:C$ and
1008 polarizability, following the molecular corridor approach using molar mass as the primary
1009 parameter characterizing a the physicochemical properties of a molecule (Shiraiwa *et al.*, 2014).
1010 Figures S9 provides the same analysis using parameterization Eq. (16). For the majority of data
1011 points the predicted E_{des}^0 values are within $\pm 10\%$ of the values shown in Fig. 14 and within the
1012 expected general uncertainty of E_{des}^0 as discussed above. Figure 14A demonstrates the impact of

1013 $O:C$ on E_{des}^0 , where alkanes, constituting the upper bound in the molecular corridor, have the
1014 lowest E_{des}^0 for a given molar mass. With increasing molecule $O:C$, E_{des}^0 increases as expected
1015 from our previous analyses and discussions. The largest impact of molecule $O:C$ is at smallest
1016 molar masses. Figure 14B corroborates the strong correlation between molar mass and
1017 polarizability. Figure S9 depicts a tighter correlation of E_{des}^0 with molar mass and polarizability
1018 due to the linear representation of polarizability (Eq. (15)). Estimates of E_{des}^0 for these SOA
1019 oxidation products will allow refinement of gas-particle partitioning timescales, specifically when
1020 temperature changes are considered as outlined in our example shown in Fig. 5.

1021 Figure 15 relates saturation vapor pressures (p^0) at 298 K, estimated using the
1022 EVAPORATION model (Compernelle et al., 2011), to estimated E_{des}^0 , derived using Eq. 14, for
1023 selected compounds relevant for atmospheric chemistry and SOA molecular corridor data from
1024 Figs. 13 (Shiraiwa et al., 2014). The top axis of Fig. 15 shows the corresponding desorption
1025 lifetimes τ_{des} at 298 K using the Frenkel equation (Eq. 1) with a pre-exponential factor A_{des} of
1026 10^{13} s^{-1} . The linear behavior in semi-logarithmic space (black solid line) reflects an exponential
1027 relation between p^0 and E_{des}^0 and a linear relation between p^0 and τ_{des} . Similar relationships are
1028 known for p^0 and ΔH_{vap} (Epstein et al., 2010), which underscores the correlation of these two
1029 quantities as observed in Fig. 11. We find, however, a steeper slope of p^0 with E_{des}^0 than previously
1030 found for p^0 and ΔH_{vap} , which suggests $E_{\text{des}}^0 < \Delta H_{\text{vap}}$ for large, oxygenated molecules with low
1031 vapor pressures. Note, however, that those gas species are lacking in our datasets. The relation of
1032 E_{des}^0 and ΔH_{vap} and its consequences for gas-particle partitioning of SOA will be further
1033 investigated in follow-up studies.

1034 Table 2 summarizes characteristic values of p^0 , E_{des}^0 , and τ_{des} for the categories of a volatility
1035 basis set (VBS) widely used for the description of SOA: intermediate volatility organic compounds

1036 (IVOC), semi-volatile organic compounds (SVOC), low volatility compounds (LVOC), extremely
1037 low volatility compounds (ELVOC), and ultra-low volatility compounds (ULVOC) (Schervish
1038 and Donahue, 2020; Donahue et al., 2009). We obtain characteristic desorption lifetimes of
1039 nanoseconds to milliseconds for VOC, milliseconds to hours for IVOC, and seconds to months for
1040 SVOC, respectively. For LVOC, ELVOC, and ULVOC we obtain τ_{des} values in the range of
1041 minutes to years and millennia. The latter, however, have to be considered as rough estimates,
1042 because the amounts of data available for parameterizing p^0 and E_{des}^0 at low volatility are very
1043 sparse. Note that these VBS categories were originally defined in terms of saturation mass
1044 concentration C^0 . To express the categories in terms of p^0 , we applied a constant conversion factor
1045 of $10^{-10} \text{ atm m}^3 \mu\text{g}^{-1}$, i.e., assuming a molar mass of 244 g mol^{-1} , for general orientation. For
1046 applications in which keeping the exact definition is required, a more nuanced conversion to vapor
1047 pressures could be achieved by parameterizing typical values of molar mass as a function of vapor
1048 pressure along the SOA molecular corridor. We provide an analogous figure displaying saturation
1049 mass concentrations in the Supplement (Fig. S10).

1050 Gas-particle partitioning plays an important role in chemical transport models, which describe
1051 the long-distance transport and chemical degradation of atmospheric constituents. In these models,
1052 gas-particle partitioning is often treated with instantaneous-equilibration approaches. Desorption
1053 lifetimes crucially determine the position of partitioning steady states and thus affect chemical
1054 degradation rates. Moreover, they have a significant influence on the validity of the instantaneous-
1055 equilibration assumption (Wilson et al., 2021; Stolzenburg et al., 2018).

1056 Adsorption and desorption processes of semi-volatile species are important in indoor
1057 environments, as large surface area-to-volume ratios indoors favor heterogeneous interactions. The
1058 deposition of semi-volatile organic compounds on impermeable indoor surfaces can lead to the

1059 formation of thin organic films (Weschler and Nazaroff, 2017). The desorption lifetime is a critical
1060 parameter for the initial film formation via multi-layer adsorption and the subsequent film growth
1061 (Lakey et al., 2021). These surface films act as reservoirs of semivolatile compounds and also
1062 serve as reaction media, affecting indoor air composition (Wang et al., 2020; Lakey et al., 2023).

1063

1064 **Summary and Conclusions**

1065 We have compiled computationally and experimentally derived desorption energy data to
1066 provide estimates of E_{des}^0 for a variety of gas species and solid, liquid, and ice substrates, thereby
1067 covering a range of relevant aerosol particle systems. The desorption energies have been placed in
1068 context with intermolecular forces. We were able to express E_{des}^0 as a function of molecular weight
1069 and $O:C$ ratio only, facilitating the application of the proposed parameterization. The important
1070 role of gas species' polarizability and dipole moment governing E_{des}^0 have been recognized. We
1071 demonstrated the importance of correct E_{des}^0 values for interpretation of multiphase chemical
1072 reactions and gas-particle partitioning, especially when extrapolating laboratory findings to
1073 atmospherically relevant temperature ranges. For example, assessment of chemical aging of
1074 aerosol particles during transport relies on E_{des}^0 values for various atmospheric oxidants.

1075 The compiled literature data allowed us to correlate E_{des}^0 with the enthalpy of vaporization and
1076 solvation, thereby evaluating the role of desorption in these interfacial processes. We identified a
1077 positive correlation between E_{des}^0 and ΔH_{vap} , where E_{des}^0 values are often larger than ΔH_{vap} . For
1078 liquid substrates, we observe a correlation with molecule oxidation state as well, indicating the
1079 importance of intermolecular interactions when looking at interfacial processes.

1080 A positive correlation has been observed between E_{des}^0 and ΔH_{solv} in liquid substrates. This
1081 trend could be related to the gas species' dipole moment and the interfacial interactions among the
1082 adsorbed gas species and molecules in the liquid phase.

1083 We demonstrated the relevance of E_{des}^0 in gas-particle partitioning and its relationship to the
1084 concept of molecular corridors. E_{des}^0 values for many SOA components were derived allowing for
1085 in detail simulation of SOA formation and growth processes. Accurate representation of particle
1086 growth and SOA formation processes requires E_{des}^0 for typically oxygenated VOCs. The relevance
1087 of E_{des}^0 for application in indoor air chemistry has been highlighted. Furthermore, in the Appendix
1088 A1 we outline the correlation of glass transition points with E_{des}^0 which adds another layer of
1089 complexity when modeling multiphase chemical reactions (through the potential of viscous phase
1090 states). Our findings identify the following areas of further research needs:

- 1091 - More adsorption and desorption data for environmentally-relevant interfaces, including
1092 multicomponent aerosol particle surfaces, are needed. Experimental and computational
1093 approaches can yield necessary E_{des}^0 values.
- 1094 - Reporting and application of adsorption and/or desorption data should consider applied
1095 standard states and adsorption models to better constrain E_{des}^0 (Donaldson et al., 2012b;
1096 Savara, 2013; Campbell et al., 2016; Knopf and Ammann, 2021).
- 1097 - Desorption kinetic measurements involving liquids with high vapor pressure are needed.
1098 Furthermore, the role of solutes in aqueous solutions on the hydrogen bonding network and
1099 in turn on the desorption process is not well understood. For example, adsorbates with
1100 hydrophilic functional groups exert greater E_{des}^0 . Systematic examination of desorption
1101 kinetics as a function of varying solute concentration and gas species $O:C$ and dipole

1102 moment are needed to improve our understanding of adsorption and desorption processes
1103 on liquid surfaces.

1104 - Experimental and theoretical multiphase chemical kinetics studies should aim to represent
1105 the typical atmospheric temperature range. This can add to further complications with
1106 regard to the underlying thermodynamics and kinetics in addition to possibly phase state
1107 changes of the substrate (Li and Knopf, 2021; Li et al., 2020; Slade et al., 2017; Knopf et
1108 al., 2005; Davies and Wilson, 2015; Chan et al., 2014; Hearn and Smith, 2007).

1109 - Advancing our understanding of the interfacial processes that govern mass
1110 accommodation, solvation, and vaporization is needed. Adsorption and desorption can play
1111 a role in these processes. However, the degree of how much impact E_{des}^0 has on gas species'
1112 solvation or vaporization depends on its relationship with ΔH_{vap} and ΔH_{solv} . Considering
1113 that aerosol particles are chemically complex and exhibit multiple phases and phase states,
1114 these advances will improve representation of gas-particle partitioning.

1115

1116 **Appendix**

1117 This appendix provides a discussion of observed correlation between E_{des}^0 and T_g , nomenclature
1118 used in this study, and lists the applied data sets to develop the E_{des}^0 parameterization and to
1119 produce correlation plots. The parameters given in Tables are also available electronically (Knopf
1120 et al., 2023).

1121

1122 **A1. Glass Transition**

1123 Molecular corridors yield also significant insight into particle phase state and viscosity. The
1124 glass transition temperature (T_g) characterizes the non-equilibrium phase change from a glassy
1125 solid state to a more pliable semi-solid state upon an increase of temperature or humidity (Koop et
1126 al., 2011b). T_g depends primarily on the molar mass and secondarily on the $O:C$ (Koop et al.,
1127 2011a; Shiraiwa et al., 2017a). Organic compounds with greater molar mass and lower volatility
1128 have higher T_g , indicating that these compounds adopt an amorphous (semi-) solid phase with
1129 higher viscosity. For weakly functionalized compounds, viscosity and T_g are sensitive to addition
1130 of carboxylic acid (COOH) and hydroxyl (OH) groups compared to carbonyl (CO) and methylene
1131 (CH_2) (Rothfuss and Petters, 2017; Galeazzo and Shiraiwa, 2022). It has been demonstrated that
1132 on average the addition of one OH group increases the viscosity by a factor of approximately 22
1133 to 45 (Grayson et al., 2017). These studies imply that hydrogen bonding may play an important
1134 role in determining viscosity, which is consistent with its role in influencing glass transition
1135 temperatures (Nakanishi and Nozaki, 2011; Van Der Sman, 2013).

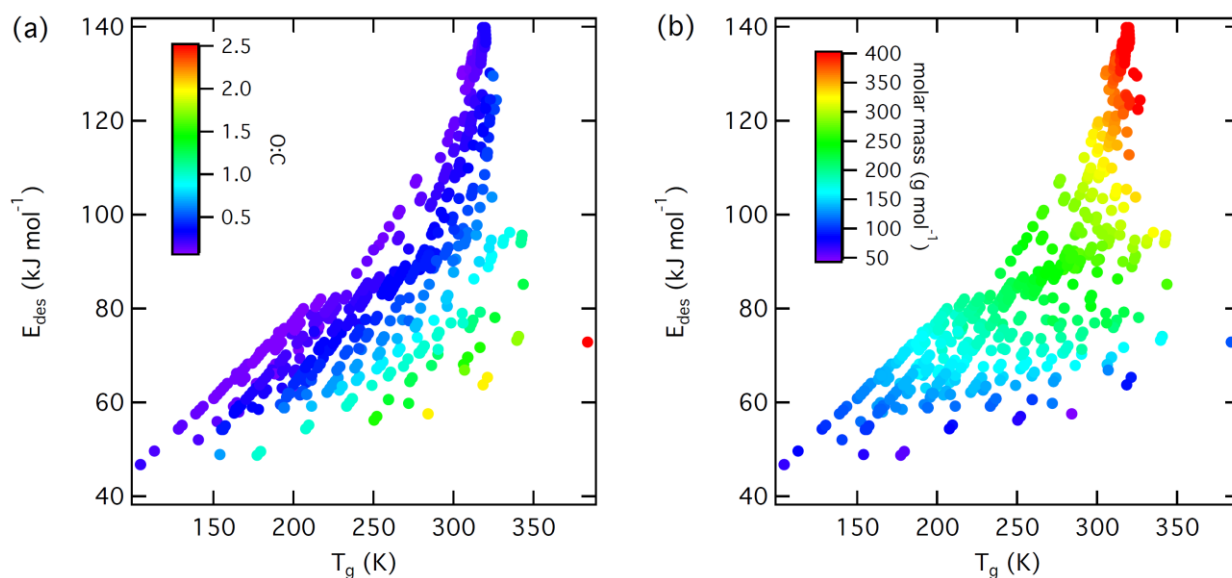

1136 Recent studies have shown that a glassy surface can be much more dynamic with lower
1137 viscosity than anticipated based on T_g and bulk viscosity (Tian et al., 2022; Zhang and Fakhraai,
1138 2017; Sikorski et al., 2010). The enhanced surface mobility, however, is mostly shown by two

1139 typical amorphous polymers of polystyrene and poly(methyl methacrylate) (Tian et al., 2022).
1140 Though it is likely that also enhanced mobility on the surface compared to the bulk is relevant for
1141 atmospheric organic matter, further studies are necessary to assess if this is applicable to
1142 atmospheric glassy SOA particles, which are highly complex multicomponent mixtures that are
1143 very different from polymers.

1144 Application of our parameterization of E_{des}^0 , we can now construct a relationship between E_{des}^0
1145 and T_g of the SOA oxidation products shown in Fig. 1. T_g was derived applying the
1146 parameterization presented in (Shiraiwa et al., 2017a) using molar mass and $O:C$ as input
1147 variables. E_{des}^0 was derived applying Eqs. (14) and (20). Since both of our parameterizations of
1148 E_{des}^0 and T_g depend on molar mass and $O:C$ ratio, it is reasonable to expect we can now construct
1149 a positive relationship between E_{des}^0 and T_g of the SOA oxidation products. Figure A1 shows that
1150 gas species with lower E_{des}^0 have lower T_g and vice versa. Figure A1A demonstrates that for gas
1151 species with same E_{des}^0 , an increase in $O:C$ results in a significant increase of T_g pointing to
1152 enhanced molecular interactions. Hence, alkanes represent species with lowest T_g at given E_{des}^0 .
1153 Figure A1B further corroborates this fact. T_g has a strong dependency on molar mass. However,
1154 for the same molar mass, T_g can vary by 100 K (which coincides with only small changes in E_{des}^0),
1155 which can now be attributed to the impact of $O:C$. In other words, increased molecular interactions
1156 can significantly increase T_g , when other parameters remain the same. Similar trends hold for E_{des}^0 ,
1157 thereby allowing to recognize that comparable molecular interactions control the properties of the
1158 amorphous phase state of a system and its E_{des}^0 . In absence of knowing the molecular structure,
1159 Fig. S11 provides the same analysis of the relationship between E_{des}^0 and T_g of the SOA oxidation
1160 products using parameterization Eq. (16) for comparison. We see that without knowing the
1161 molecular structure, a tighter correlation between E_{des}^0 and T_g is observed due to the linearization

1162 of the gas species' polarizability. Similarly to Figs. 14 and S6, the predicted E_{des}^0 values in Fig.
1163 S11 are within $\pm 10\%$ of the values shown in Fig. A1 and within the expected general uncertainty
1164 of E_{des}^0 .

1165 The correlation between E_{des}^0 and T_g serves as empirical and observational evidence. The
1166 theoretical and physical basis are yet to be established. It does not account for the potentially
1167 enhanced mobility on the surface of glassy matter (Tian et al., 2022; Zhang and Fakhraai, 2017;
1168 Sikorski et al., 2010). One would expect that surface mobility would similarly scale with the
1169 strength of intermolecular interactions. Molecules with high E_{des}^0 interact strongly with molecules
1170 of the same kind at the surface and in the bulk, are expected to also exhibit reduced dynamics in
1171 their own condensed phase (or in a mixture of similar molecules) and thus high viscosity. The
1172 presented correlation observed is meaningful for advancing our understanding of interfacial
1173 processes and supports further investigations.

1174
1175 **Figure A1.** Relationship between calculated desorption energies (E_{des}^0) of SOA precursor gases
1176 from Shiraiwa et al. (2014) and species' glass transition temperature (T_g) and its dependence on
1177 O:C (a) and molar mass (b). This analysis applies parameterizations given in Eqs. (14) and (20).

1178

τ_{des}	desorption lifetime
k_{des}	first-order desorption rate coefficient
A_{des}	pre-exponential factor
E_{des}^0	desorption energy with the energy reference of the gas molecule at rest at $T = 0$ K
γ	uptake coefficient
α_{s}	surface accommodation coefficient
Γ_{b}	normalized loss rate in the bulk-phase induced by solubility, diffusion and reaction
Γ_{sb}	normalized rate of surface to bulk transfer
Γ_{s}	normalized loss rate due to surface reaction
k_{s}	first-order rate coefficient of chemical reaction at the surface
k_{sb}	first-order rate coefficient for the transfer of molecules from the surface into the bulk (solvation)
k_{bs}	first-order rate coefficient for the transfer of molecules from the bulk to the surface
α_{b}	bulk accommodation coefficient
ΔG_{ads}^0	Gibbs free energy change of adsorption
ΔH_{ads}^0	standard enthalpy change of adsorption
ΔS_{ads}^0	standard entropy change of adsorption
κ	transmission coefficient
$(N_{\text{TS}}/\mathcal{A})^0$	standard concentration of molecules in the TS
$(N_{\text{ads}}/\mathcal{A})^0$	standard concentration of adsorbed molecules
$q_{\text{TS}}^{0'}$	standard partition functions for the TS
q_{ads}^0	standard partition functions for the adsorbate
q'_{TS}	partition functions for the TS
q_{ads}	partition functions for the adsorbate

M	molar mass
ΔH_{vap}	enthalpy of vaporization
α	polarizability
μ	dipole moment
$O:C$	oxygen to carbon ratio
ΔH_{sol}	enthalpy of solvation
ϵ_r	relative permittivity of the substrate
TPD	temperature programmed desorption
TDS	thermal desorption spectroscopy
TG-DSC	thermal gravimetry with differential scanning calorimetry
KN	Knudsen cell
MB	molecular beams
IGC	inverse gas chromatography
VM	vacuum microbalance
DRIFT	diffuse reflectance infrared fourier transform spectroscopy
FTIR	Fourier transform infrared spectroscopy
KU	kinetic uptake
VS	vibrational spectroscopy
ST	surface tension
MD	molecular dynamics
DFT	density functional theory
MC	Monte Carlo
GCMC	grand canonical Monte Carlo
ECT	embedded cluster theory
DAM	dipped adcluster model

1213

1214 **Table A5.** Compiled adsorbate-substrate interaction energies of volatile organic compounds
1215 (VOCs) on graphite (C(0001)), highly oriented pyrolytic graphite (HOPG), granular activated
1216 carbon (GAC), and soot from combustion of kerosene. Gas species, gas species' molar mass,
1217 substrate, experimental or theoretical method, desorption energy (E_{des}^0), and desorption lifetimes
1218 (τ_{des}) evaluated at 293 K using $A_{des} = 10^{13} \text{ s}^{-1}$, enthalpy of vaporization (ΔH_{vap}), gas species'
1219 polarizability (α), gas species' dipole moment (μ), substrate's relative permittivity (ϵ_r), and gas
1220 species' oxygen to carbon ration ($O:C$) are given.

Gas Species	Molar Mass / g mol^{-1}	Substrate	Method	$E_{des}^0 / \text{kJ mol}^{-1}$	$\tau_{des}^{293 \text{ K}} / \text{s}$	$\Delta H_{vap} (\text{T}) / \text{kJ mol}^{-1}$	$\alpha / 10^{-24} \text{ cm}^3$	μ / D	ϵ_r	O:C

1251

1252

1253 **Table A10.** Compiled adsorbate-substrate data for volatile aromatic gases adsorbed on water. Gas
1254 species, gas species' molar mass, substrate, experimental or theoretical method, desorption energy
1255 (E_{des}^0), and desorption lifetimes (τ_{des}) evaluated at 293 K using $A_{des} = 10^{13} \text{ s}^{-1}$, enthalpy of
1256 vaporization (ΔH_{vap}) and solvation (ΔH_{solv}), gas species' polarizability (α), gas species' dipole
1257 moment (μ), substrate's relative permittivity (ϵ_r), and gas species' oxygen to carbon ration (O:C)
1258 are given.

Gas Species	Molar Mass / g mol ⁻¹	Substrate	Method	E_{des}^0 / kJ mol ⁻¹	$\tau_{des}^{293 K}$ / s	ΔH_{vap} (T) / kJ mol ⁻¹	α / 10 ⁻²⁴ cm ³	μ / D	ϵ_r	ΔH_{solv} (T) / kJ mol ⁻¹	O:C

1299

1300 **Data availability.** Data needed to draw the conclusions in the present study are given in the paper
1301 and in the Supplement. In addition, the datasets required to reproduce the results and corresponding
1302 figures are available on Zenodo (Knopf et al., 2023).

1303

1304 **Supplement.** The supplement related to this article is available online at: XYZ

1305

1306 **Author contributions.** DAK and MS envisioned the project. DAK supervised project, performed
1307 correlation analyses, and wrote first draft of manuscript. MS performed kinetic flux modeling.
1308 MA, TB, and UP critically discussed analyses and results and were involved in representation of
1309 data. All authors discussed interpretation of the data and contributed to the writing of the paper.

1310

Table 1. Intermolecular forces for selected functional groups and gases (Jeffrey, 1997; Jeffrey and Saenger, 1991; Vinogradov and Linnell, 1971; Iupac, 1997).

Functional Group	London dispersion force	Keesom force	Hydrogen Bonding
Alkane	Increases with chain length	none	None with itself.
Ether	Increases with chain length	Slightly polar, 1 O	None with itself. H-bond acceptor (max. 2) of other molecules
Ester	Increases with chain length	More polar than ether, 1 O	None with itself. H-bond acceptor (max. 2) of other molecules
Amine	Increases with chain length	Polar, 1 N	0-2 H-bonds with itself. <i>Primary:</i> H-bond donor (max. 2) and acceptor (max. 1). <i>Secondary:</i> H-bond donor (max. 1) and acceptor (max. 1). <i>Tertiary:</i> H-bond acceptor (max. 1).
Imine	Increases with chain length	Polar, 1 N	1-2 H-bonds with itself. <i>Primary:</i> H-bond donor (max. 1) and acceptor (max. 1). <i>Secondary:</i> H-bond acceptor (max. 1). <i>Tertiary:</i> H-bond acceptor (max. 1).
Aldehyde / Ketone	Increases with chain length	Polar C=O manifest strong dipole	None with itself. H-bond acceptor (max. 2) of other molecules
Alcohol	Increases with chain length	Polar, 1 O	2 H-bonds with itself. H-bond donor (max. 1) and acceptor (max. 2).
Acid	Increases with chain length	Polar, 2 O	2 H-bonds with itself forming dimer increasing molecule size. H-bond donor (max. 1) and acceptor (max. 4).
Amide	Increases with chain length	Polar, strong dipole 1 N & 1 O	2 H-bonds with itself. H-bond donor (max. 2) and acceptor (max. 3).
Other Species	Vapor pressure	Polar	
N ₂ O ₅	100 hPa @ 3.9 °C	Yes	None with itself. H-bond acceptor (max. 12).
HONO		Yes	2 H-bonds with itself. H-bond donor (max. 1) and acceptor (max. 5).
NH ₃	100 hPa @ -71.3 °C	Yes	2 H-bonds with itself.

			H-bond donor (max. 3) and acceptor (max. 1).
HNO ₃	100 hPa @ 28.4 °C	Yes	2 H-bonds with itself. H-bond donor (max. 1) and acceptor (max. 7).
H ₂ SO ₄	100 hPa @ 248 °C	Yes	4 H-bonds with itself. H-bond donor (max. 2) and acceptor (max. 8).
H ₂ O	100 hPa @ 45.8 °C	Yes	4 H-bonds with itself. H-bond donor (max. 2) and acceptor (max. 2).

1330 **Table 2.** Characteristic estimates of desorption energies (E_{des}^0) and desorption lifetimes (τ_{des} , at
 1331 298 K) for widely used categories of secondary organic aerosol volatility basis sets (SOA-VBS):
 1332 volatile organic compounds (VOC), intermediate-volatile (IVOC), semi-volatile (SVOC), low-
 1333 volatile (LVOC), and extremely/ultra-low volatile (ELVOC/ULVOC).

Category	Volatility p^0 (atm)	Desorption Energy E_{des}^0 (kJ mol ⁻¹)	Desorption Lifetime τ_{des} (298 K)
VOC	$\geq 10^{-3}$	$\lesssim 60$	nanoseconds to milliseconds
IVOC	$\sim 10^{-5}$	~ 80	milliseconds to hours
SVOC	$\sim 10^{-9}$	~ 100	seconds to months
LVOC	$\sim 10^{-12}$	~ 120	minutes to centuries
ELVOC/ULVOC	$\lesssim 10^{-14}$	≥ 140	days to millennia
