20 **Abstract**

21 Since China's clean air action, PM<sub>2.5</sub> air quality has been improved while ozone  
22 (O<sub>3</sub>) pollution has been becoming severe. Here we apply a coupled meteorology-  
23 chemistry model (WRF-Chem) to quantify the responses of aerosol-radiation  
24 interaction (ARI), including aerosol-photolysis interaction (API) related to photolysis  
25 rate change and aerosol-radiation feedback (ARF) related to meteorological fields  
26 change, to anthropogenic emission reductions from 2013 to 2017, and their  
27 contributions to O<sub>3</sub> increases over eastern China in summer and winter. Sensitivity  
28 experiments show that the decreased anthropogenic emissions play a more prominent  
29 role for the increased MDA8 O<sub>3</sub> both in summer (+1.96 ppb vs. +0.07 ppb) and winter  
30 (+3.56 ppb vs. -1.08 ppb) than the impacts of changed meteorological conditions in  
31 urban areas. The decreased PM<sub>2.5</sub> caused by emission reduction can result in a weaker  
32 impact of ARI on O<sub>3</sub> concentrations, which poses a superimposed effect on the  
33 worsened O<sub>3</sub> air quality. The weakened ARI due to decreased anthropogenic emission  
34 aggravates the summer (winter) O<sub>3</sub> pollution by +0.81 ppb (+0.63 ppb) averaged over  
35 eastern China, with weakened API and ARF contributing 55.6% (61.9%) and 44.4%  
36 (38.1%), respectively. This superimposed effect is more significant for urban areas  
37 during summer (+1.77 ppb). Process analysis indicates that the enhanced chemical  
38 production is the dominant process for the increased O<sub>3</sub> concentrations caused by  
39 weakened ARI both in summer and winter. This study innovatively reveals the adverse  
40 effect of weakened aerosol-radiation interaction due to decreased anthropogenic  
41 emissions on O<sub>3</sub> air quality, indicating more stringent coordinated air pollution control  
42 strategies should be made for significant improvements in future air quality.

43

## 44 **1. Introduction**

45 With the implementation of clean air action since 2013, PM<sub>2.5</sub> (particulate matter  
46 with an aerodynamic equivalent diameter of 2.5 micrometers or less) concentrations  
47 have decreased significantly in China (Zhai et al., 2019; Zhang et al., 2019). However,  
48 ozone (O<sub>3</sub>) pollution is becoming worse and poses a significant challenge over eastern  
49 China, especially in the developed city clusters including Beijing-Tianjin-Hebei (BTH),  
50 Yangtze River Delta (YRD), Pearl River Delta (PRD), and Sichuan Basin (SCB) (Lu  
51 et al., 2018; Dang and Liao, 2019; Li et al., 2019; Li et al., 2021). According to  
52 observation data, Li et al. (2020) found that the daily maximum 8-h average O<sub>3</sub>  
53 concentrations (MDA8 O<sub>3</sub>) increased at a rate of 1.9 ppb a<sup>-1</sup> from 2013 to 2019 over  
54 eastern China. Elevated O<sub>3</sub> concentrations can not only decrease crop yield but also  
55 damage human health (Lelieveld et al., 2015; Yue et al., 2017; Mills et al., 2018).  
56 Therefore, it is essential to gain a comprehensive understanding about factors driving  
57 the increasing trend of O<sub>3</sub> in China in order to formulate effective prevention strategies.

58 As a secondary air pollutant, troposphere O<sub>3</sub> can be produced by nitrogen oxides  
59 (NO<sub>x</sub> = NO + NO<sub>2</sub>), carbon monoxide (CO), methane (CH<sub>4</sub>) and volatile organic  
60 compounds (VOCs) in the presence of solar radiation through photochemical reactions  
61 (Atkinson, 2000; Seinfeld and Pandis, 2006). The concentration of O<sub>3</sub> in the troposphere  
62 is influenced by changes in meteorological conditions (e.g., high temperature and low  
63 relative humidity) and its precursors emissions (e.g., NO<sub>x</sub> and VOCs) (Wang et al.,  
64 2019; Liu and Wang, 2020a,b; Shu et al., 2020). Most precursors are from  
65 anthropogenic sources, and some precursors can come from natural sources, such as  
66 biogenic VOCs and soil and lightning NO<sub>x</sub>. Moreover, particulates can also affect O<sub>3</sub>  
67 concentrations through aerosol-radiation interaction (ARI), including aerosol-  
68 photolysis interaction (API) and aerosol-radiation feedback (ARF) (Liao et al., 1999;  
69 Wang et al., 2016; Zhu et al., 2021; Yang et al., 2022), and heterogeneous chemistry  
70 on aerosol surface (Lou et al., 2014; Li et al., 2019; Liu and Wang, 2020b). Many  
71 studies have found that the decreased PM<sub>2.5</sub> can be one of the driving factors  
72 contributing to the increased O<sub>3</sub> concentrations (Li et al., 2019; Liu and Wang, 2020b;

73 Shao et al., 2021). Li et al. (2019) analyzed GEOS-Chem simulation results and pointed  
74 out that the reductions in PM<sub>2.5</sub> concentrations from 2013 to 2017 in North China Plain  
75 (NCP) could decrease the sink of HO<sub>2</sub> on aerosol surface, which would result in the  
76 increase in O<sub>3</sub> concentrations. When heterogeneous reactions were considered in WRF-  
77 CMAQ, Liu and Wang (2020b) found that decreased PM<sub>2.5</sub> concentrations weakened  
78 the uptake of reactive gases (mainly HO<sub>2</sub> and O<sub>3</sub>) which led to the increase in O<sub>3</sub>  
79 concentrations over China from 2013 to 2017. However, the contribution of weakened  
80 aerosol-radiation interaction due to substantial decreases in PM<sub>2.5</sub> under clean air action  
81 to the increased O<sub>3</sub> has not been systematically quantified. Furthermore, previous  
82 studies mainly focus on the increased summer O<sub>3</sub> (Li et al., 2019; Liu and Wang,  
83 2020a,b; Shu et al., 2020; Shao et al., 2021), but underlying reasons driven the changes  
84 in winter O<sub>3</sub> is unclear. Li et al. (2021) pointed out that O<sub>3</sub> pollution has been extended  
85 into cold seasons under the emission control measures. Therefore, this study aims to  
86 quantify the response of aerosol-radiation interaction to anthropogenic emission  
87 reduction from 2013 to 2017, with the mainly focus on the contribution to changed O<sub>3</sub>  
88 concentrations over eastern China both in summer and winter.

89 Aerosol-radiation interaction (ARI) can alter photolysis rates through aerosol-  
90 photolysis interaction (API) and meteorological variables through aerosol-radiation  
91 feedback (ARF) to influence the formation of O<sub>3</sub> (Yang et al., 2022). API can affect O<sub>3</sub>  
92 directly by reducing the photochemical reactions, which weaken the chemical  
93 contribution and reduce the surface O<sub>3</sub> concentrations. ARF indirectly affects O<sub>3</sub>  
94 concentrations by altering meteorological variables, e.g. by reducing the height of the  
95 planetary boundary layer. The suppressed planetary boundary layer can weaken the  
96 vertical mixing of O<sub>3</sub> by turbulence and affect the concentration of O<sub>3</sub> precursors. Hong  
97 et al. (2020) used WRF-CMAQ in conjunction with future emission scenarios to find  
98 that weakened ARF due to reduced aerosol concentration has either negative or positive  
99 impacts on the daily maximum 1-h average O<sub>3</sub> concentration in eastern China from  
100 2010 to 2050 due to the changed precursor level caused by the weakened ARF. By  
101 using WRF-CMAQ, Liu and Wang (2020b) reported that weakened API could increase  
102 the MDA8 O<sub>3</sub> concentrations by 0.3 ppb in urban areas from 2013 to 2017. Zhu et al.

103 (2021) used WRF-Chem to investigate the impact of weakened ARF on air pollutants  
104 over NCP during COVID-19 lockdown and reported that the weakened ARF would  
105 increase the O<sub>3</sub> concentrations by 7.8% due to the increased northwesterly and planetary  
106 boundary layer height caused by the weakened ARF. In general, previous studies  
107 mainly examined the impact of either weakened ARF or API, systematic analysis about  
108 the total and the respective impacts of changed API and/or ARF on O<sub>3</sub> over eastern  
109 China both in summer and winter from 2013 to 2017 have not been conducted.

110 The objective of this manuscript is to examine the impacts of aerosol-radiation  
111 interactions (ARI), including the effects of aerosol-photolysis interaction (API) and  
112 aerosol-radiation feedback (ARF), on O<sub>3</sub> concentrations over eastern China both in  
113 summer and winter by using the online coupled WRF-Chem model, with the main focus  
114 on their responses to clean air action. Process analysis is also applied to explore the  
115 prominent physical/chemical process responsible for the changed impacts of API and/or  
116 ARF on surface O<sub>3</sub>. This study is believed to provide insights into the role of weakened  
117 ARI on O<sub>3</sub> levels over eastern China not only in summer, but also in winter. In Section  
118 2, we describe the model configuration, numerical experiments, observational data, and  
119 the integrated process rate analysis. Model evaluation is presented in Section 3. Results  
120 and discussions are presented in Section 4. Conclusions are provided in Section 5.

## 121 **2. Methodology**

### 122 2.1 Model configuration

123 The model used in this study is an online-coupled meteorology-chemistry model,  
124 Weather Research and Forecasting with Chemistry model (WRF-Chem v3.7.1), that  
125 can simulate meteorological fields and concentrations of gases and aerosols  
126 simultaneously (Grell et al., 2005; Skamarock et al., 2008). Figure S1 shows the  
127 simulated domain that covers most regions of China with a horizontal resolution of 27  
128 km and grid points of 167 (west–east) × 167 (south–north). The model contains 32  
129 vertical levels extending from the surface to 50 hPa, with the first 16 layers located  
130 below 2 km to resolve fine boundary layer processes. The enclosed black line in Figure  
131 S1 represents the eastern China (22–41.5 °N, 102–123 °E), and the four heavily polluted

132 regions are also selected for analysis, including BTH (36.0-41.5 °N, 113-119.5 °E),  
133 YRD (29.5-32.5 °N, 118-122 °E), PRD (21-23.5 °N, 112-116 °E), and SCB (27.5-  
134 31.5 °N, 102.5-107.5 °E), respectively.

135 The National Center for Environmental Prediction (NCEP) Final Analysis dataset  
136 (FNL) with a spatial resolution of  $1^\circ \times 1^\circ$  and 6-hour temporal resolution are used to  
137 provide the meteorological initial and lateral boundary conditions. The chemical initial  
138 and boundary conditions for the WRF-Chem model are taken from the outputs of  
139 Community Atmosphere Model with Chemistry (CAM-Chem).

140 The Carbon Bond Mechanism Z (CBM-Z) is applied as the gas-phase chemical  
141 mechanism (Zaveri and Peters, 1999), and the full 8-bin MOSAIC (Model for  
142 Simulating Aerosol Interactions and Chemistry) aerosol module with aqueous  
143 chemistry is used to simulate aerosol evolution (Zaveri et al., 2008). In MOSAIC  
144 module, aerosols are assumed to be internally mixed into 8 bins (0.039–0.078  $\mu\text{m}$ ,  
145 0.078–0.156  $\mu\text{m}$ , 0.156–0.312  $\mu\text{m}$ , 0.312–0.625  $\mu\text{m}$ , 0.625–1.25  $\mu\text{m}$ , 1.25–2.5  $\mu\text{m}$ , 2.5–  
146 5.0  $\mu\text{m}$  and 5.0–10  $\mu\text{m}$ ), and each bin considers all major aerosol species, such as sulfate  
147 ( $\text{SO}_4^{2-}$ ), nitrate ( $\text{NO}_3^-$ ), ammonium ( $\text{NH}_4^+$ ), black carbon (BC), organic carbon (OC), and  
148 other inorganic mass. The impacts of aerosols on photolysis rates are calculated by  
149 using the Fast-J scheme (Wild et al., 2000). The following physical parameterizations  
150 are used in WRF-Chem. The Rapid Radiative Transfer Model for general circulation  
151 models (RRTMG) scheme is used to treat both shortwave and longwave radiation in  
152 the atmosphere (Iacono et al., 2008). The Purdue Lin microphysics scheme (Lin et al.,  
153 1983) and the Grell 3D ensemble scheme (Grell, 1993) are used to describe the cloud  
154 microphysical and cumulus convective processes. The Noah land surface scheme (Chen  
155 and Dudhia, 2001) and the Monin-Obukhov surface scheme (Foken, 2006) are used to  
156 simulate land-atmosphere interactions. The planetary boundary layer is characterized  
157 by Yonsei University PBL scheme (Hong et al 2006). The main physical and chemical  
158 schemes used in this study are summarised in Table S1.

159 In this study, Multi-resolution Emission Inventory for China (MEIC;  
160 <http://www.meicmodel.org/>) in 2013 and 2017 are used as the anthropogenic emissions  
161 of particles and gases (Zheng et al., 2018). Biogenic emissions are calculated online by

162 using the Model of Emissions of Gases and Aerosols from Nature (MEGAN) developed  
163 by Guenther et al. (2006).

## 164 2.2 Numerical experiments

165 Seven sensitivity experiments are designed (Table 1). Here are the detailed  
166 descriptions:

167 (1) BASE\_17E17M: This baseline experiment is coupled with the interactions  
168 between aerosol and radiation, which includes the impacts of API and ARF. Both  
169 the meteorological field and anthropogenic emission are from the year of 2017.

170 (2) BASE\_13E13M: Same as BASE\_17E17M, but the meteorological field and  
171 anthropogenic emission are from the year of 2013.

172 (3) NOAPI\_17E17M: Same as BASE\_17E17M, but the impact of API is not  
173 considered by turning off the aerosol effect in the photolysis module, following the  
174 method described in Yang et al. (2022).

175 (4) NOALL\_17E17M: Same as BASE\_17E17M, but neither the impact of API nor  
176 ARF is considered by zeroing the aerosol optical properties in the optical module,  
177 following the method described in Yang et al. (2022).

178 (5) BASE\_13E17M: Same as BASE\_17E17M, but the anthropogenic emission is from  
179 the year of 2013.

180 (6) NOAPI\_13E17M: Same as NOAPI\_17E17M, but the anthropogenic emission is  
181 from the year of 2013.

182 (7) NOALL\_13E17M: Same as NOALL\_17E17M, but the anthropogenic emission is  
183 from the year of 2013.

184 Figure 1 detailedly presents the schematic overview of designed numerical  
185 experiments. As shown in Fig. 1, the differences between BASE\_17E17M and  
186 BASE\_13E13M (BASE\_17E17M minus BASE\_13E13M) represent the changed  $O_3$   
187 ( $\Delta O_3$ ) due to variations in meteorology and anthropogenic emissions from 2013 to 2017.  
188 The differences between BASE\_13E17M and BASE\_13E13M (BASE\_13E17M minus  
189 BASE\_13E13M) show the impact of changed meteorological conditions on  $O_3$   
190 ( $\Delta O_3_{MET}$ ) from 2013 to 2017. The differences between BASE\_17E17M and

191 BASE\_13E17M (BASE\_17E17M minus BASE\_13E17M) indicate the impact of  
192 anthropogenic emission reductions on O<sub>3</sub> ( $\Delta O_3\_EMI$ ) from 2013 to 2017.

193 The impacts of aerosol-radiation interaction (ARI) on O<sub>3</sub> under different  
194 anthropogenic emission scenarios (i.e., strong anthropogenic emission levels in year  
195 2013, and weaker anthropogenic emission levels in year 2017) can be analyzed as the  
196 differences between BASE\_17E17M and NOALL\_17E17M (BASE\_17E17M minus  
197 NOALL\_17E17M, denote as  $\Delta O_3\_ARI_{17E}$ ), and BASE\_13E17M and  
198 NOALL\_13E17M (BASE\_13E17M minus NOALL\_13E17M, denote as  $\Delta O_3\_ARI_{13E}$ ).  
199 The  $\Delta O_3\_ARI_{17E}$  means that the impact of ARI on O<sub>3</sub> at the condition of both the  
200 meteorological field and anthropogenic emission are from the year of 2017, and the  
201  $\Delta O_3\_ARI_{13E}$  means that the effect of ARI on O<sub>3</sub> at the state of meteorological field used  
202 in the year 2017 and anthropogenic emission applied in the year 2013. In order to  
203 quantify the impacts caused by the decreased anthropogenic emission from 2013 to  
204 2017, the impacts of changed meteorological variables should be removed by fixing the  
205 meteorological fields in year 2017 in sensitivity experiments. Thus, the impact of  
206 weakened ARI due to decreased anthropogenic emission from 2013 to 2017 on O<sub>3</sub>  
207 (denote as  $\Delta O_3\_ \Delta ARI\_EMI$ ) can be quantified from the differences between  
208  $\Delta O_3\_ARI_{17E}$  and  $\Delta O_3\_ARI_{13E}$ . Similarly, the impacts of weakened API (denote as  
209  $\Delta O_3\_ \Delta API\_EMI$ ) and ARF (denote as  $\Delta O_3\_ \Delta ARF\_EMI$ ) due to decreased  
210 anthropogenic emission on O<sub>3</sub> can also be estimated from the differences between  
211 (BASE\_17E17M minus NOAPI\_17E17M, denote as  $\Delta O_3\_API_{17E}$ ) and  
212 (BASE\_13E17M minus NOAPI\_13E17M, denote as  $\Delta O_3\_API_{13E}$ ), and between  
213 (NOAPI\_17E17M minus NOALL\_17E17M, denote as  $\Delta O_3\_ARF_{17E}$ ) and  
214 (NOAPI\_13E17M minus NOALL\_13E17M, denote as  $\Delta O_3\_ARF_{13E}$ ), respectively.  
215 Detailed descriptions can be found in Fig. 1.

216 Simulation periods are integrated from 30 May to 30 June (denoted as summer)  
217 and 29 November to 31 December (denoted as winter) both in 2013 and 2017. To avoid  
218 potential deviations caused by long-term model integration, each simulation is re-  
219 initialized every eight days, with the first 40 hours as the model spin-up. The complete  
220 simulation includes five model cycles. Simulation results from the BASE\_17E17M

221 case during summer and winter are used to evaluate the model performance. If not  
222 otherwise specified, the time in this paper is the local time, and the synergetic impacts  
223 of ARF and API are equal to the impact of ARI (i.e.,  $ARI=ARF+API$ ).

### 224 2.3 Observational data

225 Meteorological observations of temperature ( $T_2$ ), relative humidity ( $RH_2$ ), wind  
226 speed ( $WS_{10}$ ) and wind direction ( $WD_{10}$ ) provided by the NOAA's National Climatic  
227 Data Center (<https://www.ncei.noaa.gov/>) are used to validate the model  
228 meteorological performance. In this study, 353 meteorological stations are selected and  
229 the locations are shown as red dots in Fig. S1. Observed surface  $PM_{2.5}$ ,  $O_3$  and  $NO_2$   
230 concentrations in eastern China are obtained from the China National Environmental  
231 Monitoring Center, which can be downloaded from <http://beijingair.sinaapp.com>. To  
232 ensure the data quality, a single site with at least 500 actual observations during the  
233 simulated period are used for model evaluation. A total of 1296 sites, as shown in Fig.  
234 2a, are obtained. Photolysis rates of nitrogen dioxide ( $NO_2$ ) ( $J[NO_2]$ ) measured at the  
235 Peking University site (39.99 °N, 116.31 °E) are also used to evaluate the model  
236 performance.

### 237 2.4 Integrated process rate analysis

238 Process analysis techniques, i.e., integrated process rate (IPR) analysis, can be  
239 used in grid-based Eulerian models (e.g., WRF-Chem) to obtain contributions of each  
240 physical/chemical process to variations in pollutant concentrations. Eulerian models  
241 utilize the numerical technique of operator splitting to solve continuity equations for  
242 each species into several simple ordinary differential equations or partial differential  
243 equations that only contain the influence of one or two processes (Gipson, 1999).

244 In order to quantitatively elucidate individual contributions of physical and  
245 chemical processes to  $O_3$  concentration changes due to weakened ARI, the integrated  
246 process rate (IPR) methodology is applied in this study. IPR analysis is an advanced  
247 tool to evaluate the key process for  $O_3$  concentration variation (Shu et al., 2016; Zhu et  
248 al., 2021; Yang et al., 2022). In this study, the IPR analysis tracks hourly (e.g., one time  
249 step) contribution to  $O_3$  concentration variation from four main processes, including

250 vertical mixing (VMIX), net chemical production (CHEM), horizontal advection  
251 (ADVH), and vertical advection (ADVZ). VMIX is initiated by turbulent process and  
252 closely related to PBL development, which influences O<sub>3</sub> vertical gradients. CHEM  
253 represents the net O<sub>3</sub> chemical production (chemical production minus chemical  
254 consumption). ADVH and ADVZ represent transport by winds. We define ADV as the  
255 sum of ADVH and ADVZ.

### 256 **3. Model Evaluation**

257 Simulation results of BASE\_17E17M are used to compare with the observations  
258 to evaluate the model performs before interpreting the impacts of aerosol-radiation  
259 interaction on surface-layer ozone concentration.

#### 260 3.1 Evaluation for meteorology

261 Figure S2 shows the time series of observed and simulated T<sub>2</sub>, RH<sub>2</sub>, WS<sub>10</sub>, and  
262 WD<sub>10</sub> averaged over the 353 meteorological stations in China during summer and  
263 winter in 2017. Statistical performances of simulated meteorological parameters  
264 compared with ground-based observations are shown in Table 2. Simulations track well  
265 with observed T<sub>2</sub> with the correlation coefficient (R) of 0.99 and 0.92, but underestimate  
266 T<sub>2</sub> with the mean bias (MB) of -1.0 and -2.0 K in summer and winter, respectively.  
267 Simulated RH<sub>2</sub> agree reasonably well with observations with R of 0.97 and 0.87, and  
268 small normalized mean biases (NMB) are found in summer and winter with values of  
269 3.2% and 3.5%, respectively. WS<sub>10</sub> is slightly overpredicted with the MB of 1.6-2.1 m  
270 s<sup>-1</sup>. The R and root-mean-square error (RMSE) of WS<sub>10</sub> are 0.77-0.82 and 1.6-2.1 m s<sup>-1</sup>,  
271 respectively. Large bias in wind speed can be partly caused by unresolved  
272 topographical features (Jimenez and Dudhia, 2012). The NMB of WD<sub>10</sub> ranges from -  
273 3.9% to -2.6% and the R ranges from 0.40 to 0.69, respectively. As shown in Fig. S3,  
274 the predicted J[NO<sub>2</sub>] match well with the observations with R of 0.93-0.94 and NMB  
275 of 4.8%-12.3%. In general, the simulated meteorological variables fairly well  
276 agreement with the observations.

#### 277 3.2 Evaluation for air pollutants

278 Figure 2 shows the spatial-temporal variations of observed and simulated near-  
279 surface PM<sub>2.5</sub>, O<sub>3</sub> and NO<sub>2</sub> concentrations averaged over eastern China during summer  
280 and winter in 2017. As demonstrated in Figs. 2(a1) and (c1), WRF-Chem model  
281 reasonably well reproduces the spatial distribution of observed PM<sub>2.5</sub>, with high values  
282 over large city cluster. The predicted O<sub>3</sub> concentrations can also reproduce the spatial  
283 variation of the observed concentrations (Figs. 2(a2) and (c2)). NO<sub>2</sub> is an important  
284 precursor of O<sub>3</sub> and aerosol, a good performance on NO<sub>2</sub> is necessary. From Figs. 2(a3)  
285 and (c3), the model can well reproduce the spatial distribution of observed NO<sub>2</sub>.  
286 Although the distributions of simulated air pollutants are in good with the observations,  
287 biases still exist, which may be due to the uncertain in the emission inventories. Figures  
288 2(b1-b3) and 2(d1-d3) show the temporal profiles of observed and simulated surface-  
289 layer air pollutants averaged over monitoring sites and the grid cell containing the  
290 monitor site in eastern China. The statistical metrics are also shown in Table 2. As  
291 shown in Figs. 2(b1) and (d1), the model tracks well with the diurnal variation of PM<sub>2.5</sub>  
292 over the eastern China, with R of 0.63 and 0.80, respectively. But the model slightly  
293 underestimates the concentrations of PM<sub>2.5</sub> with MB of -6.3 and -10.1 μg m<sup>-3</sup>,  
294 respectively, in summer and winter. Simulated O<sub>3</sub> agree reasonably well with  
295 observations with R of 0.90 and 0.86, and small MB are found in summer and winter  
296 with values of -0.6 and 2.8 ppb, respectively. The model tracks the daily variation of  
297 observed NO<sub>2</sub> reasonably well, with R of 0.73 and 0.83. But the model slightly  
298 underestimates the NO<sub>2</sub> against measurements, with MB of -1.5 and -4.5 ppb,  
299 respectively, in summer and winter. In general, WRF-Chem model can well reproduce  
300 the features of observed meteorology and air pollutants over eastern China.

### 301 3.3 Evaluation for changes in air pollutants from 2013 to 2017

302 Figure 3 demonstrates the spatial distribution of changed summer (left) and winter  
303 (right) surface (a, b) PM<sub>2.5</sub> and (c, d) MDA8 O<sub>3</sub> from 2013 to 2017. As shown in Figs.  
304 3(a) and 3(b), the observed concentrations of PM<sub>2.5</sub> in eastern China are significantly  
305 reduced both in summer (-16.2 μg m<sup>-3</sup>) and winter (-56.0 μg m<sup>-3</sup>), and these changes  
306 can be well captured by the model (-14.3 μg m<sup>-3</sup> for summer and -49.8 μg m<sup>-3</sup> for winter).

307 Therefore, the model can reproduce the observed decrease in PM<sub>2.5</sub> levels from 2013 to  
308 2017. As shown in Figs. 3(c) and 3(d), the model reasonably well reproduces the  
309 seasonal patterns of changed surface MDA8 O<sub>3</sub> over the eastern China during summer  
310 and winter from 2013 to 2017. In summer, both the observations and simulations show  
311 the increased (decreased) MDA8 O<sub>3</sub> in YRD (PRD and SCB), while the model can not  
312 simulate the positive changes in MDA8 O<sub>3</sub> over BTH, and the potential reasons may be  
313 that this study did not consider the effect of changes in aerosol heterogeneous reactions.  
314 Li et al. (2019) found that the weakened uptake of HO<sub>2</sub> on aerosol surfaces was the  
315 main reason for the O<sub>3</sub> increase over BTH. In contrast to the changes in summer,  
316 observed MDA8 O<sub>3</sub> in winter generally increased over the eastern China, which can be  
317 well reproduced by the model.

## 318 **4. Results and Discussion**

### 319 4.1 Impacts of changed meteorology and anthropogenic emission on O<sub>3</sub>

320 The strategy of clean air action decreased the anthropogenic emission of NO<sub>x</sub>, but  
321 the changes in anthropogenic VOCs emissions were unobvious (Fig. S4), which might  
322 influence the O<sub>3</sub> formation sensitive regime and the O<sub>3</sub> concentration. Figure 4 shows  
323 the spatial distributions of changed summer and winter MDA8 O<sub>3</sub> concentrations from  
324 2013 to 2017 due to changed anthropogenic emissions alone and changed  
325 meteorological conditions alone. As shown in Fig. 4(a), the concentration of summer  
326 MDA8 O<sub>3</sub> from 2013 to 2017 was increased in city clusters, but it was decreased in  
327 rural regions. This discrepancy might be explained by the ozone formation regimes in  
328 urban (typically VOCs-limited) and rural (typically NO<sub>x</sub>-limited) areas during summer  
329 (Li et al., 2019; Wang et al., 2019). Contrary to the phenomenon in summer, decreased  
330 anthropogenic emissions lead to a uniform increase in winter MDA8 O<sub>3</sub> over the whole  
331 eastern China (Fig. 4(c)). These different spatial variation characteristics in summer and  
332 winter could be explained by the different ozone formation regimes in winter (VOCs-  
333 limited) and summer (NO<sub>x</sub>-limited) (Fig. S5, Jin and Holloway, 2015). From Figs. 4(b)  
334 and (d), the impacts of changed meteorological conditions on MDA8 O<sub>3</sub> varied by  
335 regions, ranging from -24.9 (-14.0) to 17.0 (7.3) ppb in summer (winter). Focusing on

336 the four developed city clusters, compared with 2013, the meteorological conditions in  
337 the summer of 2017 promoted the generation of O<sub>3</sub> in the YRD region (Fig. 8(a3)), but  
338 suppressed the generation of O<sub>3</sub> in the BTH (Fig. 8(a2)), PRD (Fig. 8(a4)) and SCB  
339 (Fig. 8(a5)) regions. In PRD and SCB, the changes in MDA8 O<sub>3</sub> due to meteorology  
340 even have a greater impact than that by emission changes, which highlights the  
341 significant role of meteorology on summer O<sub>3</sub> variations.

#### 342 4.2 Impacts of weakened aerosol-radiation interaction on O<sub>3</sub>

343 Figures S6a (S7a) and S6b (S7b) present the spatial distribution of the impacts of  
344 ARF, API and ARI on surface MDA8 O<sub>3</sub> concentrations in summer (winter) under  
345 different anthropogenic emission conditions in year 2017 and year 2013, respectively.  
346 As shown in Fig. S6, summer MDA8 O<sub>3</sub> are significantly reduced over eastern China,  
347 ARF, API and ARI decrease the surface MDA8 O<sub>3</sub> concentrations by 0.23 (0.59) ppb,  
348 1.09 (1.54) ppb and 1.32 (2.13) ppb under low (high) anthropogenic emission  
349 conditions in year 2017 (year 2013), respectively. The changes in MDA8 O<sub>3</sub>  
350 concentrations due to aerosol-radiation interaction under low emission condition are  
351 weaker than that under high emission condition. This is because the concentration of  
352 aerosols in year 2013 is higher than that in year 2017, and then its impact on  
353 meteorological conditions and J[NO<sub>2</sub>] is greater (Fig. S8). As shown in Fig. S7a, ARF,  
354 API and ARI decrease the winter MDA8 O<sub>3</sub> concentrations by 0.38 ppb (-0.9%), 1.59  
355 ppb (-4.1%) and 1.96 ppb (-5.1%) in year 2017, respectively. Compared to the impacts  
356 under relatively high anthropogenic emission conditions in year 2013, the reduction of  
357 surface MDA8 O<sub>3</sub> concentrations caused by ARF, API and ARI are also greater, with  
358 the values of 0.62 ppb (-1.6%), 1.98 ppb (-5.4%) and 2.59 ppb (-7.1%), respectively.  
359 Both API and ARF reduce O<sub>3</sub> concentrations, and the reduction in O<sub>3</sub> caused by API is  
360 greater than that caused by ARF both in summer and winter.

361 Further, the significant reduction in PM<sub>2.5</sub> due to clean air action (Fig. S9) will  
362 lead to an increase in O<sub>3</sub> concentrations as the weakened effects of aerosols on O<sub>3</sub>.  
363 Therefore, this study further quantifies the effects of  $\Delta O_3_{\Delta ARF\_EMI}$ ,  
364  $\Delta O_3_{\Delta API\_EMI}$  and  $\Delta O_3_{\Delta ARI\_EMI}$  ( $\Delta O_3_{\Delta ARI\_EMI} = \Delta O_3_{\Delta ARF\_EMI} + \Delta$

365  $O_3\_ΔAPI\_EMI$ ) on  $O_3$  air quality. As shown in Figs. 5(a1-a3), the surface MDA8  $O_3$   
366 in summer are increased over most of eastern China due to  $ΔO_3\_ΔARF\_EMI$ ,  
367  $ΔO_3\_ΔAPI\_EMI$  and  $ΔO_3\_ΔARI\_EMI$ . The largest increases in MDA8  $O_3$   
368 concentrations due to  $ΔO_3\_ΔARF\_EMI$  and  $ΔO_3\_ΔAPI\_EMI$  are found in the  
369 developed four city clusters, with the increase larger than 4 ppb. Overall,  
370  $ΔO_3\_ΔARF\_EMI$ ,  $ΔO_3\_ΔAPI\_EMI$  and  $ΔO_3\_ΔARI\_EMI$  lead to the increase in  
371 surface MDA8  $O_3$  by 0.36 ppb, 0.45 ppb and 0.81 ppb averaged over eastern China  
372 during summer, respectively. As shown in Fig. 5(a4-a6), the  $ΔO_3\_ΔARF\_EMI$ ,  
373  $ΔO_3\_ΔAPI\_EMI$  and  $ΔO_3\_ΔARI\_EMI$  can also cause an increase in winter MDA8  $O_3$   
374 concentrations by 0.24 ppb, 0.39 ppb and 0.63 ppb, respectively. In general, weakened  
375 aerosol-radiation interaction due to reduced anthropogenic emission from 2013 to 2017  
376 can exacerbate ozone pollution both in summer and winter.

377 In order to explore the mechanism of the impacts of  $ΔO_3\_ΔARI\_EMI$  on MDA8  
378  $O_3$ , we resolve the changed  $O_3$  into the contributions from chemical and physical  
379 processes. Figure 6 presents the accumulated changes in  $O_3$  and each process  
380 contribution from 09:00 to 16:00 LST by the  $ΔO_3\_ΔAPI\_EMI$ ,  $ΔO_3\_ΔARF\_EMI$  and  
381  $ΔO_3\_ΔARI\_EMI$  during summer and winter. As shown in Fig 6, the enhanced chemical  
382 production is the dominant process leading to the increase in  $O_3$  concentrations over  
383 eastern China and the four city clusters both in summer and winter. The leading factor  
384 of enhancement in  $O_3$  over BTH are inconsistent with that over eastern China, and the  
385 enhancement of  $O_3$  concentration in BTH is mainly due to  $ΔO_3\_ΔARF\_EMI$ . But the  
386 leading factor of enhancement in  $O_3$  over SCB are consistent with that in eastern China,  
387 the enhancement of  $O_3$  concentration is mainly due to  $ΔO_3\_ΔAPI\_EMI$  both in summer  
388 and winter. Moreover, the enhancement of  $O_3$  concentration in BTH, YRD and PRD is  
389 mainly due to  $ΔO_3\_ΔARF\_EMI$  during winter, which is opposite to that of eastern  
390 China. The leading factors for the increase of  $O_3$  concentration in different city clusters  
391 are different. The enhancement of  $O_3$  concentration in most areas is caused by  
392  $ΔO_3\_ΔAPI\_EMI$ , whereas the increase in  $O_3$  concentration in BTH, YRD and PRD  
393 areas is dominated by  $ΔO_3\_ΔARF\_EMI$  in winter. In general, the weakened aerosol-  
394 radiation interaction caused by emission reduction would promote the chemical

395 production of O<sub>3</sub> and increase the O<sub>3</sub> concentrations over eastern China in summer and  
396 winter.

397 In order to explore the reason for the increase in O<sub>3</sub> chemical production, we  
398 further analyzed the variation of HO<sub>x</sub> (HO+HO<sub>2</sub>) concentration from 2013 to 2017. As  
399 the aerosol concentration decreases, its influence on solar radiation is weakened and  
400 photolysis is enhanced, leading to an increase in HO<sub>x</sub> levels. It can be seen from Fig.  
401 S10 that the concentration of HO<sub>x</sub> increases both in winter and summer. The increase  
402 in HO<sub>x</sub> will promote the conversion of NO to NO<sub>2</sub>, which will lead to the accumulation  
403 of O<sub>3</sub> concentration.

404 Figure 7 shows the changed summer and winter surface-layer MDA8 O<sub>3</sub>  
405 concentrations caused by anthropogenic emission reduction from 2013 to 2017 with  
406 ( $\Delta O_3\_EMI$ ) and without ( $\Delta O_3\_NOARI$ ) ARI, including the effects of weakened ARI on  
407 the effectiveness of emission reduction for O<sub>3</sub> air quality ( $\Delta O_3\_ARI\_EMI$ , which is  
408 also equal to  $\Delta O_3\_EMI$  minus  $\Delta O_3\_NOARI$ ). As shown in Figs. 7(a1) and 7(a4), the  
409 surface-layer MDA8 O<sub>3</sub> concentrations increased mainly in urban areas during summer  
410 and increased uniformly in winter due to anthropogenic emission reduction from 2013  
411 to 2017 without the impact of ARI. When the effect of ARI is considered, the  
412 concentrations of MDA8 O<sub>3</sub> are increased more than that when ARI is not taken into  
413 account (Figs. 7(a2) and 7(a5)). The consequences of weakened ARI resulted from  
414 anthropogenic emission reduction on MDA8 O<sub>3</sub> concentrations are shown in Figs. 7(a3)  
415 and 7(a6). From Figs. 7(a3) and 7(a6) we can find that the concentrations of MDA8 O<sub>3</sub>  
416 are increased in both summer and winter over eastern China. Therefore,  
417  $\Delta O_3\_ARI\_EMI$  makes the superimposed impact on the effectiveness of anthropogenic  
418 emission reduction for the increased MDA8 O<sub>3</sub> concentrations from 2013 to 2017 over  
419 eastern China. However, during summer, the worsened O<sub>3</sub> air quality due to weakened  
420 ARI can only be found in scattered city clusters (e.g., BTH, YRD and PRD in Fig.  
421 7(a3)). During winter, it will increase MDA8 O<sub>3</sub> concentrations over nearly the whole  
422 eastern China (Fig. 7(a6)).

423 We also average the observed MDA8 O<sub>3</sub> concentrations of monitoring sites in the  
424 urban areas and the simulation value for the grid cell containing the monitoring site to

425 further examine the impacts of changed meteorological conditions, anthropogenic  
426 emissions and ARI on O<sub>3</sub> levels in densely populated urban areas (Fig. 8). Given that  
427 most of the monitoring stations with 5 years of continuous observations are located in  
428 urban areas. Therefore, these monitoring stations and the grid cells containing the  
429 monitoring stations can be considered as urban areas in this study (Liu and Wang,  
430 2020b). As shown in Figs. 8(a1) and 8(b1), the changes in observed MDA8 O<sub>3</sub> over  
431 urban areas in eastern China from 2013 to 2017 can be well captured by WRF-Chem  
432 both in summer and winter. In summer, changed meteorological conditions from 2013  
433 to 2017 has little impact on the variations in MDA8 O<sub>3</sub> over the urban areas, while the  
434 contribution of emission reductions to increased MDA8 O<sub>3</sub> is significant. In winter,  
435 changed meteorological conditions is unfavorable for the increase in MDA8 O<sub>3</sub> from  
436 2013 to 2017, indicating the worsened ozone pollution driven by the changed  
437 anthropogenic emission. What's more, the  $\Delta O_3\_ \Delta ARI\_EMI$  has significant effect on  
438 the increased MDA8 O<sub>3</sub> in summer from 2013 to 2017 with the value of +1.77 ppb  
439 (87.6%), but its impacts in winter are smaller, only +0.42 ppb (11.8%), which is  
440 consistent with the results in Li et al. (2021). The increased MDA8 O<sub>3</sub> concentration  
441 over urban areas in summer caused by  $O_3\_ \Delta ARI\_EMI$  in this study is 1.77 ppb, which  
442 is compared to the value of 2.12 ppb increase caused by weakened aerosol  
443 heterogeneous reactions quantified by Liu and Wang (2020b). Meanwhile, the  
444 contributions of  $\Delta O_3\_ \Delta API\_EMI$  and  $\Delta O_3\_ \Delta ARF\_EMI$  to the increase in O<sub>3</sub>  
445 concentration averaged over urban areas in eastern China are almost the same in  
446 summer (0.79 vs. 0.98) and winter (0.20 vs. 0.22). In general, we find that the  
447 enhancement of O<sub>3</sub> concentrations both in summer and winter is mainly caused by the  
448 factor of reduced anthropogenic emissions. Furthermore, the contributions of  $\Delta$   
449  $O_3\_ \Delta API\_EMI$  and  $\Delta O_3\_ \Delta ARF\_EMI$  to the increases in O<sub>3</sub> concentrations from 2013  
450 to 2017 over urban areas are almost the same during summer and winter.

#### 451 4.3 Discussions

452 (1) The CBMZ gas-phase chemistry coupled with MOSAIC aerosol module

453 (CBMZ-MOSAIC for short) used in this study does not include secondary organic  
454 aerosol (SOA), then we applied three additional chemical mechanisms that consider  
455 SOA, namely, RADM2 gas-phase chemistry coupled with MADE/SORGAM aerosol  
456 module (RADM2-MADE/SORGAM for short), CBMZ gas-phase chemistry coupled  
457 with MADE/SORGAM aerosol module (CBMZ-MADE/SORGAM for short), and  
458 MOZART gas-phase chemistry coupled with MOSAIC aerosol module (MOZART-  
459 MOSAIC for short), to test the impact of ARI on O<sub>3</sub> with and without SOA for the  
460 scenario of BASE\_17E17M.

461 Figures S11 shows the temporal variations of observed and simulated PM<sub>2.5</sub> and  
462 O<sub>3</sub> concentrations over eastern China for the three additional chemical mechanisms.  
463 Comparing with the observed PM<sub>2.5</sub> (O<sub>3</sub>) concentrations, the MOZART-MOSAIC  
464 showed the best performance in December 2017, with the R of 0.73 (0.79) and NMB  
465 of -18.7% (-20.5%). Therefore, we further used this mechanism to simulate the air  
466 pollutant concentrations during the period of June 2017. As shown in Fig. S11 (a4, b4),  
467 the temporal variations of observed PM<sub>2.5</sub> (O<sub>3</sub>) can be well captured by this mechanism  
468 with R of 0.56 (0.91) and NMB of -1.7% (-20.3%).

469 Finally, we investigated the effect of ARI on O<sub>3</sub> from the results of CBMZ-  
470 MOSAIC (this mechanism applied in this manuscript which does not include SOA) and  
471 MOZART-MOSAIC (this mechanism includes SOA and performs the best simulation  
472 results comparing with RADM2-MADE/SORGAM and CBMZ-MADE/SORGAM).  
473 As shown in Fig. S12, summer (winter) MDA8 O<sub>3</sub> is significantly reduced over eastern  
474 China, ARI reduces the surface MDA8 O<sub>3</sub> concentrations by 1.32 (1.96) ppb and 1.85  
475 (1.60) ppb by CBMZ-MOSAIC and MOZART-MOSAIC, respectively. The O<sub>3</sub>  
476 reductions are of comparable magnitude in these two schemes. Therefore, we can  
477 conclude that although the CBMZ-MOSAIC applied in this manuscript does not take  
478 into account the formation of SOA and its associated effects, the aerosol radiative  
479 effects on O<sub>3</sub> concentrations not only in the pattern of spatial-temporal distribution but  
480 also in the order of magnitude are consistent with the results when the SOA simulation  
481 mechanism is considered.

482 As shown in Fig. S13, the mean SOA simulated by RADM2-MADE/SORGAM,

483 CBMZ-MADE/SORGAM, and MOZART-MOSAIC are 0.29, 0.45 and 0.94  $\mu\text{g m}^{-3}$ ,  
484 accounting for 3.4%, 3.8%, and 4.4% of  $\text{PM}_{2.5}$  concentrations in winter 2017,  
485 respectively. From Fig. S14, the mean SOA simulated from MOZART-MOSAIC is 0.90  
486  $\mu\text{g m}^{-3}$ , account for 9.1% of  $\text{PM}_{2.5}$  in summer 2017. Model simulated SOA  
487 concentrations are generally underestimated in most current chemical transport models  
488 (Zhang et al., 2015; Zhao et al., 2015). The low SOA concentrations simulated by the  
489 model can be explained by low emissions of biogenic and anthropogenic VOCs (key  
490 precursors of SOA), but a thorough investigation of this underestimation is outside the  
491 scope of this manuscript and it will be discussed in our future work.

492 (2) The impacts of aerosol heterogeneous reactions (HET) on  $\text{O}_3$  have not been  
493 considered in this manuscript due to the uncertainty and inconsistency of the  
494 heterogeneous uptake shown in previous observation and simulation studies (Liu and  
495 Wang., 2020b; Tan et al., 2020; Shao et al., 2021). Liu and Wang. (2020b) found that  
496 the rapid decrease of  $\text{PM}_{2.5}$  was the primary contributor for the summer  $\text{O}_3$  increase  
497 through weakening the heterogeneous uptake of hydroperoxy radical ( $\text{HO}_2$ ). However,  
498 Tan et al. (2020) launched a field campaign in NCP and proposed a contradicting  
499 opinion about the importance of the impact of HET on  $\text{O}_3$ . Shao et al. (2021)  
500 summarized that different heterogeneous uptake on the aerosol surface applied in the  
501 model simulation (e.g., 0.20 vs. 0.08) would cause significant deviations in simulated  
502 ozone concentrations (e.g.,  $\text{O}_3$  increased by 6% vs.  $\text{O}_3$  increased by 2.5%). Previous  
503 laboratory studies indicate that the dependence of the uptake coefficient on aerosol  
504 composition and RH means that a single assumed value for heterogeneous uptake used  
505 in numerical simulations can lead to large uncertainties (Lakey et al., 2015; Taketani et  
506 al., 2009; Zou et al., 2019). Therefore, the uncertainty in the heterogeneous uptake value  
507 used in the numerical simulation will finally amplify the deviation in model results.  
508 Meanwhile, our manuscript devoted to quantifying the effects of ARI on  $\text{O}_3$ , rather than  
509 the impacts of heterogeneous reactions on  $\text{O}_3$ . The absence of heterogeneous chemistry  
510 on aerosol surface may result in underestimation of the effect of aerosol on  $\text{O}_3$ , which  
511 will be considered in our future work.

512 (3) There may be an interaction between API and ARF. However, in this study we

513 discuss the role of API and ARF separately, which may ignore the effects of interactions  
514 between API and ARF on O<sub>3</sub>. This may affect our results, and we will discuss their  
515 interaction in our future studies.

## 516 **5 Conclusions**

517 In this study, the impact of weakened aerosol-radiation interaction (ARI) due to  
518 decreased anthropogenic emissions on surface O<sub>3</sub> ( $\Delta O_3_{\Delta ARI\_EMI}$ ) over eastern  
519 China is mainly analyzed by using an online-coupled regional chemistry transport  
520 model WRF-Chem. Simulation results generally reproduce the spatiotemporal  
521 characteristics of observations with correlation coefficients of 0.63-0.90 for pollutant  
522 concentrations and 0.40-0.99 for meteorological parameters, respectively.

523 Sensitivity experiments show that the changes in MDA8 O<sub>3</sub> from 2013 to 2017  
524 over eastern China vary spatially and seasonally, and the decreased anthropogenic  
525 emission plays a more prominent role for the MDA8 O<sub>3</sub> increase than the impact of  
526 changed meteorological conditions both in summer and winter. Furthermore, the  
527 decreased PM<sub>2.5</sub> concentrations due to reduced anthropogenic emissions can result in a  
528 weaker impact of ARI on O<sub>3</sub> concentrations, which finally pose a superimposed effect  
529 on the worsened O<sub>3</sub> air quality. For urban areas over eastern China,  $\Delta O_3_{\Delta ARI\_EMI}$   
530 has a significant effect on the increase of MDA8 O<sub>3</sub> in summer with the value of +1.77  
531 ppb, accounting for 87.6% of the increased value caused by decreased anthropogenic  
532 emissions, but the impacts in winter are smaller (+0.42 ppb), accounting for 11.8% of  
533 the increased value caused by decreased anthropogenic emissions. For the whole  
534 regions over eastern China, the enhancement of MDA8 O<sub>3</sub> by  $\Delta O_3_{\Delta ARI\_EMI}$  is +0.81  
535 (+0.63) ppb, with  $\Delta O_3_{\Delta API\_EMI}$  and  $\Delta O_3_{\Delta ARF\_EMI}$  contributing for 55.6%  
536 (61.9%) and 44.4% (38.1%) in summer (winter), respectively. Process analysis shows  
537 that the enhanced O<sub>3</sub> chemical production is the dominant process for the increased O<sub>3</sub>  
538 concentrations caused by  $\Delta O_3_{\Delta ARI\_EMI}$  both in summer and winter.

539 Generally, since China's clean air action from 2013, the decreased PM<sub>2.5</sub>  
540 concentrations due to reduced anthropogenic emissions can worsen O<sub>3</sub> air quality by  
541 the weakened interactions between aerosol and radiation, which is a new and an

542 important implication for understanding the causes driving the increases in O<sub>3</sub> level  
543 over eastern China. Therefore, our results highlight that more carefully designed multi-  
544 pollutants coordinated emissions control strategies are needed to reduce the  
545 concentrations of PM<sub>2.5</sub> and O<sub>3</sub> simultaneously.

546

547

548 **Data availability**

549 The observed hourly surface concentrations of air pollutants are derived from the China  
550 National Environmental Monitoring Center (<http://www.cnemc.cn>). The observed  
551 surface meteorological data are obtained from NOAA's National Climatic Data Center  
552 (<https://gis.ncdc.noaa.gov/maps/ncei/cdo/hourly>). The photolysis rates of nitrogen  
553 dioxide in Beijing are provided by Xin Li ([li\\_xin@pku.edu.cn](mailto:li_xin@pku.edu.cn)). The simulation results  
554 can be accessed by contacting Lei Chen ([chenlei@nuist.edu.cn](mailto:chenlei@nuist.edu.cn)) and Hong Liao  
555 ([hongliao@nuist.edu.cn](mailto:hongliao@nuist.edu.cn)).

556

557 **Author contributions**

558 HY, LC, and HL conceived the study and designed the experiments. HY and LC  
559 performed the simulations and carried out the data analysis. JZ, WW, and XL provided  
560 useful comments on the paper. HY prepared the paper with contributions from all co-  
561 authors.

562

563 **Competing interests**

564 The authors declare that they have no competing interests.

736 **Table 1.** Descriptions of model sensitivity experiments.

<b>Cases</b>	<b>Anthropogenic emission</b>	<b>Meteorological field</b>	<b>API<sup>a</sup></b>	<b>ARF<sup>a</sup></b>
<b>BASE_17E17M</b>	2017	2017	On	On
<b>BASE_13E13M</b>	2013	2013	On	On
<b>NOAPI_17E17M</b>	2017	2017	Off	On
<b>NOALL_17E17M</b>	2017	2017	Off	Off
<b>BASE_13E17M</b>	2013	2017	On	On
<b>NOAPI_13E17M</b>	2013	2017	Off	On
<b>NOALL_13E17M</b>	2013	2017	Off	Off

737 <sup>a</sup>API means aerosol-photolysis interaction, ARF means aerosol-radiation feedback.

738

739 **Table 2.** Statistical parameters of the simulated 2 m temperature ( $T_2$ , k), 2 m relative humidity ( $RH_2$ , %), 10 m wind speed ( $WS_{10}$ ,  $m\ s^{-1}$ ), 10 m  
740 wind direction ( $WD_{10}$ , °), photolysis rate of  $NO_2$  ( $J[NO_2]$ ,  $10^{-3}\ s^{-1}$ ),  $PM_{2.5}$  ( $\mu g\ m^{-3}$ ),  $O_3$  (ppb), and  $NO_2$  (ppb) against observations during summer  
741 and winter in 2017. There are 1296 air pollutant monitoring stations and 353 meteorological stations.

Variable	Summer						Winter					
	$O^a$	$M^a$	$R^b$	$MB^c$	$NMB^d$ (%)	$RMSE^e$	$O^a$	$M^a$	$R^b$	$MB^c$	$NMB^d$ (%)	$RMSE^e$
$T_2$	295.3	294.2	0.99	-1.0	-3.2	1.0	275.0	272.8	0.92	-2.0	-74.1	2.5
$RH_2$	68.1	71.0	0.97	2.2	3.2	3.6	58.1	60.6	0.87	2.1	3.5	6.5
$WS_{10}$	2.6	4.2	0.77	1.6	61.6	1.6	2.6	4.7	0.82	2.1	83.2	2.1
$WD_{10}$	175.7	170.9	0.40	-4.6	-2.6	16.9	192.6	184.6	0.69	-7.5	-3.9	17.4
$J[NO_2]$	2.6	2.7	0.93	0.1	4.8	1.2	1.0	1.2	0.94	0.1	12.3	0.6
$PM_{2.5}$	31.0	24.8	0.63	-6.3	-20.2	8.3	69.0	58.9	0.80	-10.1	-14.6	15.6
$O_3$	39.7	38.9	0.90	-0.6	-1.6	6.9	17.7	20.5	0.86	2.8	15.7	5.0
$NO_2$	12.7	11.2	0.73	-1.5	-12.0	4.5	23.3	18.7	0.83	-4.5	-19.4	5.6

742 <sup>a</sup> $O$  and  $M$  are the averages for observed and simulated results, respectively.  $O = \frac{1}{n} \times \sum_{i=1}^n O_i$ ,  $M = \frac{1}{n} \times \sum_{i=1}^n M_i$ .

743 <sup>b</sup> $R$  is the correlation coefficient between observations and model results.  $R = \frac{\sum_{i=1}^n |(O_i - O) \times (M_i - M)|}{\sqrt{\sum_{i=1}^n (O_i - O)^2 + \sum_{i=1}^n (M_i - M)^2}}$ .

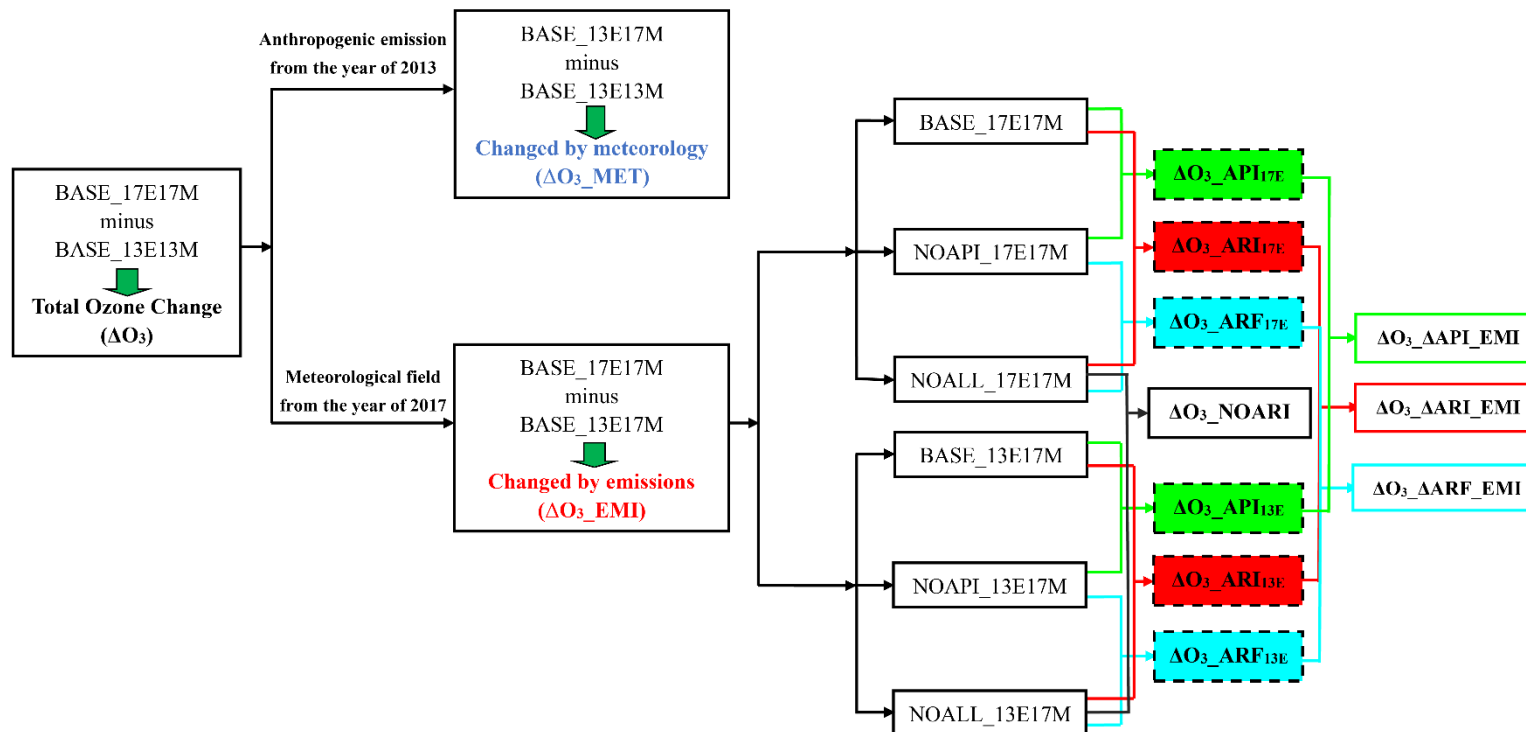

744 <sup>c</sup> $MB$  is the mean bias between observations and model results.  $MB = \frac{1}{n} \times \sum_{i=1}^n (M_i - O_i)$ .

745 <sup>d</sup> $NMB$  is the normalized mean bias between observations and model results.  $NMB = \frac{1}{n} \times \sum_{i=1}^n \frac{M_i - O_i}{O_i} \times 100\%$ .

746 <sup>e</sup> $RMSE$  is the root-mean-square error of observations and model results.  $RMSE = \sqrt{\frac{1}{n} \times \sum_{i=1}^n (M_i - O_i)^2}$ .

747 In the above  $O_i$  and  $M_i$  are the hourly observed and simulated data, respectively, and  $n$  is the total number of hours.

748

749

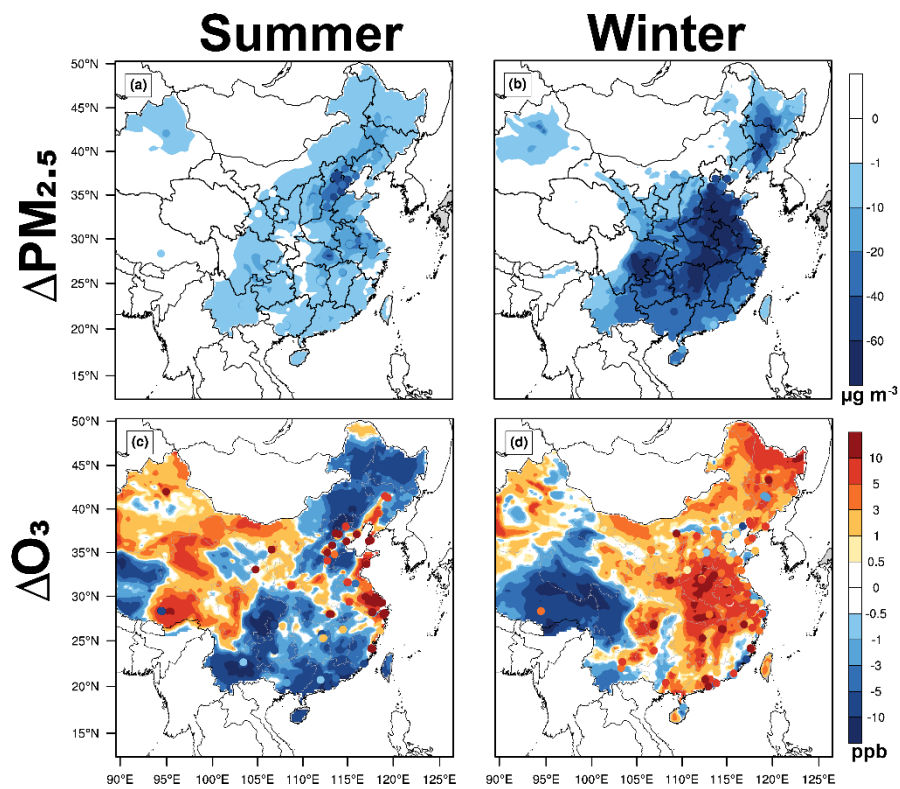

750 **Figure 1.** Schematic overview of numerical experiments. 17E17M (13E13M) means meteorological fields and anthropogenic emissions are from  
 751 the year of 2017 (2013). 13E17M means anthropogenic emissions are from the year of 2013 but meteorological fields are at year 2017.  $\Delta\text{O}_3_{\text{MET}}$ ,  
 752  $\Delta\text{O}_3_{\text{EMI}}$  and  $\Delta\text{O}_3$  mean the impacts of changed meteorological conditions, changed anthropogenic emissions and their combined effects on  $\text{O}_3$ ,  
 753 respectively.  $\Delta\text{O}_3_{\text{API}_{17\text{E}(13\text{E})}}$ ,  $\Delta\text{O}_3_{\text{ARF}_{17\text{E}(13\text{E})}}$  and  $\Delta\text{O}_3_{\text{ARI}_{17\text{E}(13\text{E})}}$  mean the impacts of aerosol-photolysis interaction, aerosol-radiation feedback  
 754 and aerosol-radiation interaction on  $\text{O}_3$  under different emission conditions, respectively.  $\Delta\text{O}_3_{\text{NOARI}}$  means the changed  $\text{O}_3$  concentration by  
 755 reduced anthropogenic emissions without considering aerosol-radiation interaction.  $\Delta\text{O}_3_{\Delta\text{API\_EMI}}$ ,  $\Delta\text{O}_3_{\Delta\text{ARF\_EMI}}$  and  $\Delta\text{O}_3_{\Delta\text{ARI\_EMI}}$   
 756 represent the impacts of weakened aerosol-photolysis interaction, aerosol-radiation feedback and aerosol-radiation interaction due to decreased  
 757 anthropogenic emission on  $\text{O}_3$  concentration, respectively.

758

759 **Figure 2.** Spatial distributions of observed (circle) and simulated (shade)  $PM_{2.5}$ ,  $O_3$  and  $NO_2$  concentrations averaged over (a1-a3) summer and  
 760 (c1-c3) winter in 2017. Time series of observed (black dots) and simulated (red lines) hourly  $PM_{2.5}$ ,  $O_3$  and  $NO_2$  concentrations averaged over the  
 761 whole observation sites in eastern China during (b1-b3) summer and (d1-d3) winter in 2017.

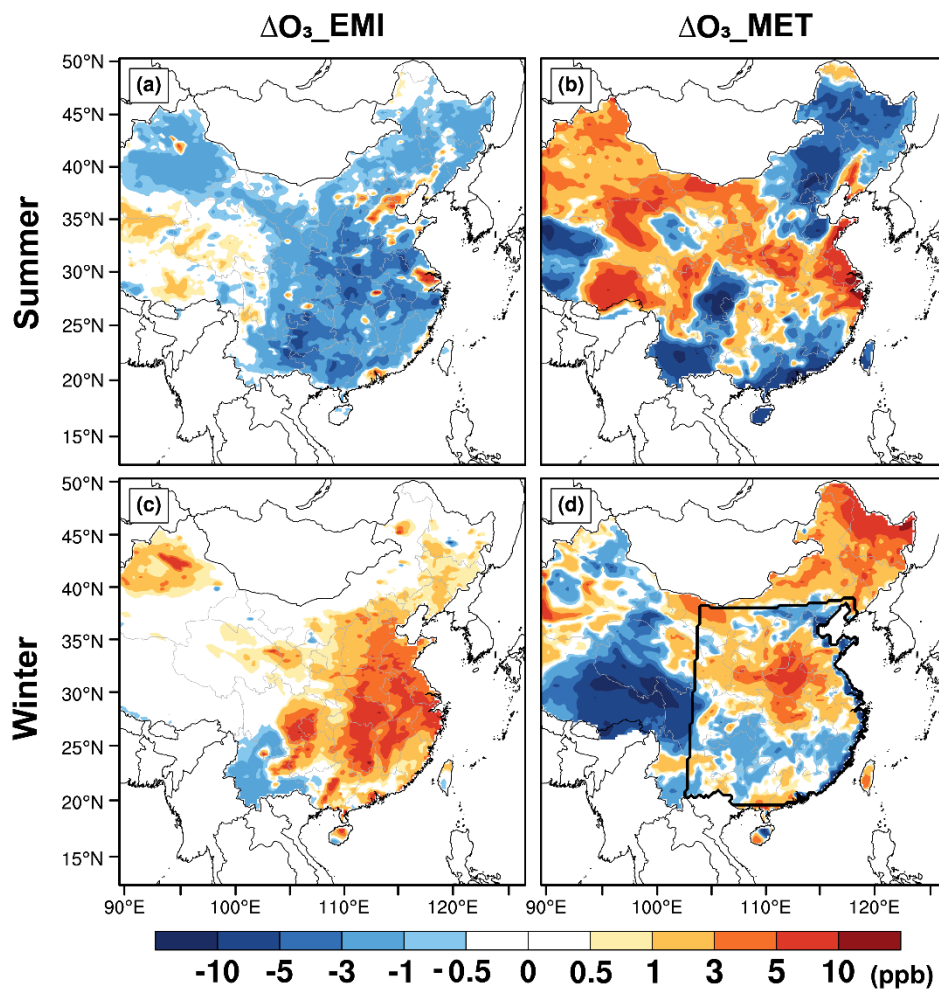

762

763

764 **Figure 3.** Spatial distribution of changed summer (left) and winter (right) surface (a, b)  
 765 PM<sub>2.5</sub> and (c, d) MDA8 O<sub>3</sub> from 2013 to 2017. Observed changes in surface PM<sub>2.5</sub>  
 766 MDA8 O<sub>3</sub> are also marked with colored circles.

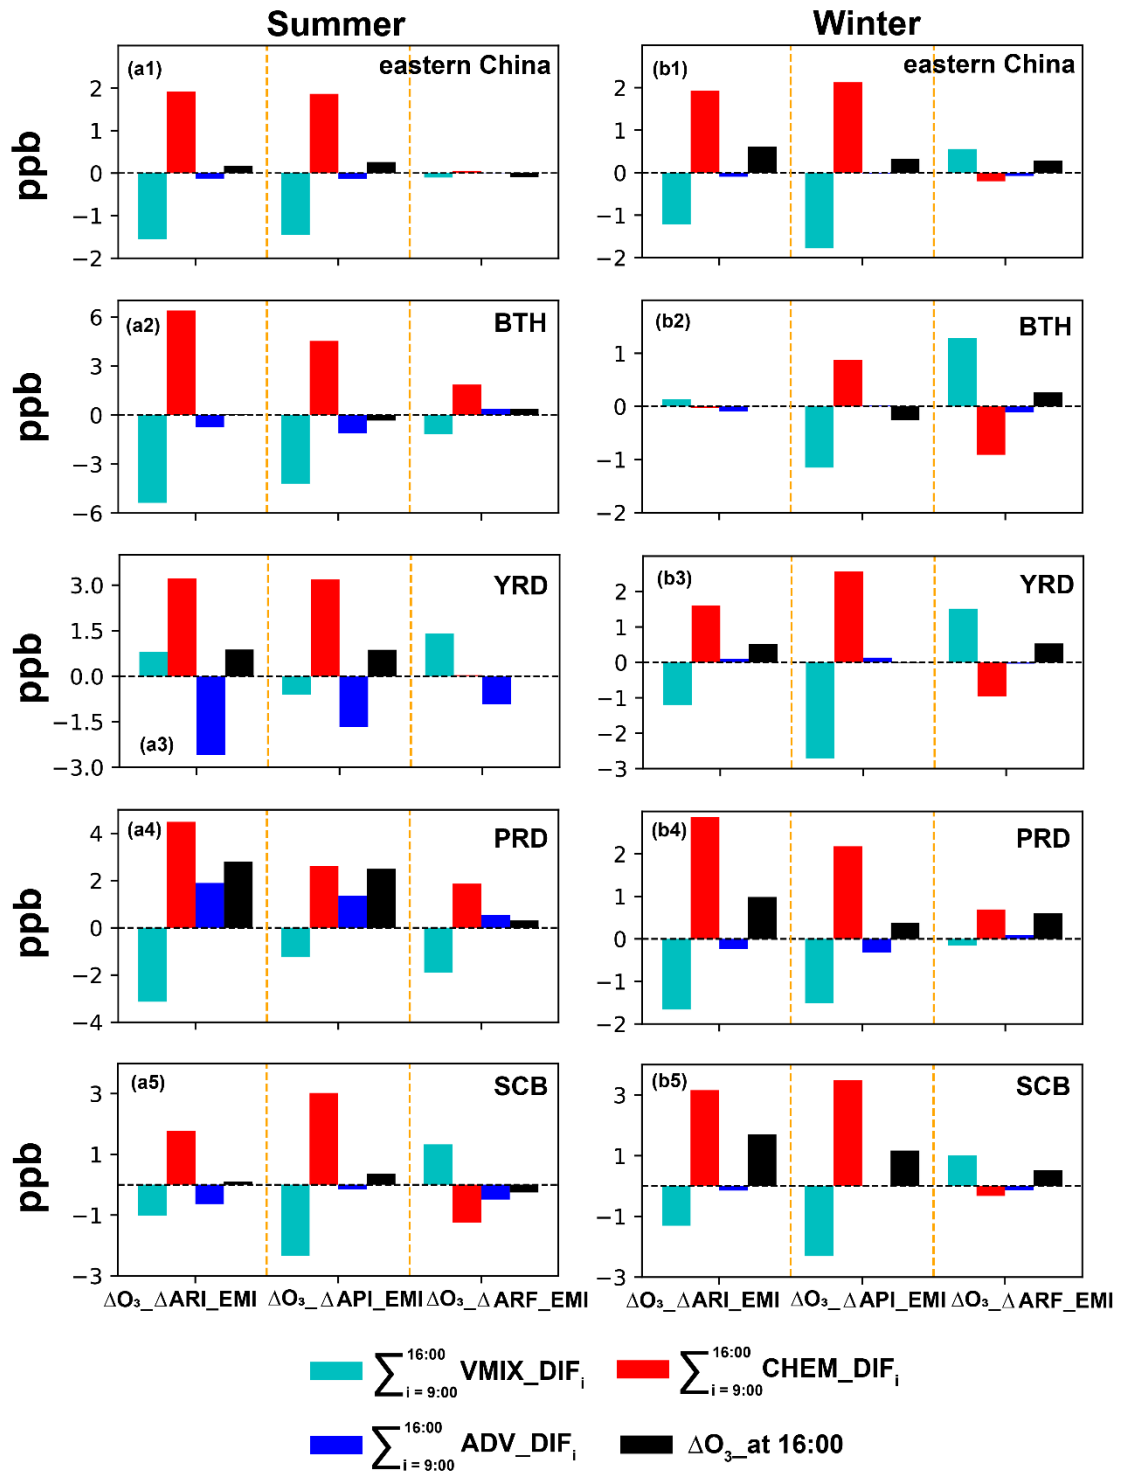

767

768 **Figure 4.** Spatial distribution of changed summer (upper) and winter (bottom) surface-  
 769 layer MDA8 O<sub>3</sub> from 2013 to 2017 due to (a, c) changed anthropogenic emissions alone  
 770 and (b, d) changed meteorological fields alone. The enclosed black line in (d)  
 771 represents eastern China.

772

773 **Figure 5.** Impacts of  $\Delta O_3_{\Delta ARF\_EMI}$ ,  $\Delta O_3_{\Delta API\_EMI}$ , and  $\Delta O_3_{\Delta ARI\_EMI}$  on  
 774 summer (upper) and winter (bottom) surface-layer MDA8 O<sub>3</sub> concentrations. The  
 775 enclosed black line in (a1) represents eastern China and the four developed city clusters.  
 776 The mean changes over eastern China are also shown at the top of each panel. Detailed  
 777 information about  $\Delta O_3_{\Delta ARF\_EMI}$ ,  $\Delta O_3_{\Delta API\_EMI}$ , and  $\Delta O_3_{\Delta ARI\_EMI}$  can be  
 778 found in Figure 1.

779

780 **Figure 6.** Accumulated changes in each process from 09:00 to 16:00 LST and the  
 781 changed  $\text{O}_3$  concentrations due to  $\Delta \text{O}_3 \text{ } \Delta \text{ARI\_EMI}$  in summer (left column) and winter  
 782 (right column). The regions of eastern China, Beijing-Tianjin-Hebei (BTH), Yangtze  
 783 River Delta (YRD), Pearl River Delta (PRD) and Sichuan Basin (SCB) are indicated  
 784 on the upper right side of each panel.

785

786

787 **Figure 7.** Spatial distribution of changed summer (upper) and winter (bottom) surface-  
 788 layer MDA8 O<sub>3</sub> concentrations from sensitivity simulations. **(a1, a4)** Effects of  
 789 anthropogenic emission reduction on MDA8 O<sub>3</sub> without ARI. **(a2, a5)** Effects of  
 790 anthropogenic emission reduction on MDA8 O<sub>3</sub> with ARI. **(a3, a6)** Effects of weakened  
 791 ARI on the effectiveness of emission reduction for O<sub>3</sub> air quality.  
 792

793

794 **Figure 8.** The observed (OBS, black bars) and simulated (SIM, red bars) changes in  
 795 (left) summer and (right) winter surface-layer MDA8 O<sub>3</sub> from 2013 to 2017.  
 796 Contributions of changed meteorological conditions alone (MET, blue bars), changed  
 797 anthropogenic emissions alone (EMI, purple bars), changed aerosol-photolysis  
 798 interaction alone ( $\Delta$ API\_EMI, green bars), and changed aerosol-radiation feedback  
 799 alone ( $\Delta$ ARF\_EMI, cyan bars) are also shown. Observations are calculated from the  
 800 monitoring sites in the analyzed region, while the corresponding gridded simulations  
 801 are averaged for SIM. (a1-b1), (a2-b2), (a3-b3), (a4-b4) and (a5-b5) represent the  
 802 urban areas in eastern China, Beijing-Tianjin-Hebei (BTH), Yangtze River Delta  
 803 (YRD), Pearl River Delta (PRD), and Sichuan Basin (SCB), respectively.
