**Abstract:** The pile-slab retaining wall has gained widespread utilization in rockfall mitigation engineering, attributed to its excellent impact resistance, substantial interception height, and reliable structural durability. The numerical experiments investigate the dynamic response of a pile-slab retaining wall under the various impact conditions of rockfall. Results reveal that: (1) during the impact process, the stress, strain, and concrete damage of the structure gradually spread from the impact center to entire structure and ultimately result in permanent deformation; (2) the lateral displacement of the pile at the ground surface and the concrete damage under the pile as the impact center is greater than those under the slab as the impact center, implying that the impact location has a significant influence on the stability of the structure; (3) there is a positive correlation between the response indexes (impact force, interaction force, lateral deformation of pile and slab, concrete damage, and the impact velocities; (4) within the discussed impact scenarios, the rockfall peak impact force, the ratio of peak impact force to peak interaction force, and lateral displacement of pile at the ground surface had strong linear relationships with rockfall energy. Utilizing this relationship, the estimated maximum impact energy that the pile-slab retaining wall can withstand is 905 kJ in this study when the structure top is taken as the impact point.

**Keywords:** rockfall, pile-slab retaining wall, numerical simulation, dynamic response

### List of symbols

$P$	Actual lateral soil resistance (kPa).	$F_{dm}$	Peak impact force (kN).
$P_u$	Ultimate lateral soil resistance (kPa).	$F_{im}$	Peak interaction force (kN).
$S_{u\_cu}$	Consolidated isotropic undrained tri-axial shear strength of soil (kPa/m).	$\alpha$	Ratio of the peak impact force to the peak interaction force (%).
$y$	Actual lateral soil deformation (m).	$S_{mpt}$	Maximum the lateral displacement of pile at the ground surface (mm).
$B$	Pile width (m).	$N_d$	Number of damage failure units.
$z$	Depth below the ground surface (m).	$\beta$	Ratio of damage failure units to overall structure units (%).
$S_p$	Shape correction factor of pile section.	$m$	Impactor mass (kg).
$E$	Initial kinetic energy of impactor.	$v$	Initial velocity of impactor (m/s).

## 1. Introduction

Rockfall disaster are a great threat to roads, railways, buildings and inhabitants in mountainous terrain (Hung et al., 2014; Crosta and Agliardi, 2004; Shen et al., 2019). It can be described as a

---

33 process that the rapid bouncing, rolling and sliding movement of one (or several) boulders down a  
34 slope (Peila and Ronco, 2009). Muraishi et al. (2005) surveyed 607 rockfall events found that about  
35 68% of rockfall events have an impact energy of less than 100 kJ, whereas 90% have less than 1000  
36 kJ. Chau et al. (2002) indicated that the rotational kinetic energy of rockfall only accounts for 10%  
37 of the total kinetic energy. To mitigate such geological hazards, scholars and engineers have  
38 proposed different types of technical solutions. Two primary categories of defensive measures are  
39 commonly employed: active and passive. Active protection measures mainly include: masonry  
40 protection, reinforcement protection (grouting, anchor rod, and anchor cable), initiative protective  
41 net, etc (Yang et al., 2019). Passive protection measures include: passive flexible protection (Yu et  
42 al., 2021), rockfall shed gallery (Zhao et al., 2018), rockfall retaining wall, etc. Considering many  
43 factors such as technology and economy, rockfall retaining wall is often used in practical engineerin  
44 (Volkwein et al., 2011).

45 Currently, various types of retaining walls are utilized in engineering projects aimed at  
46 intercepting rockfall. These include masonry retaining walls, reinforced concrete (RC) retaining  
47 walls, reinforced soil retaining walls, and pile-slab retaining walls (PSRW). Due to inherent  
48 structural weakness of these walls, their ability to absorb the impact energy from rockfall is limited  
49 (Mavrouli et al., 2017). To enhance the impact resistance, the reinforced concrete retaining walls  
50 have been utilized (Yong et al., 2020). These structures can intercept rockfall impact energy ranging  
51 approximately from 120 to 500 kJ (Maegawa et al., 2011). To prevent concrete from being damaged  
52 by the direct impact of rockfall, a buffer layer is generally added in front of the structure for  
53 protection, such as reinforced soil and gabion cushion (Perera et al., 2021). Although the impact  
54 resistance of the structure has been improved, there is still a problem of limited interception height.  
55 When the required interception height is large, the foundation size has to be increased to prevent the  
56 structures from overturning. In order to mitigate against rockfall events involving higher energy  
57 levels, numerous researchers have proposed the implementation of reinforced soil retaining walls.  
58 Extensive studies have been conducted in this regard, demonstrating that the structures can  
59 effectively intercept rockfall impact energies exceeding 5000 kJ (Lambert et al., 2009). Moreover,  
60 geosynthetic have proven to be efficacious in reducing wall stresses (Lu et al., 2021). However, the  
61 structure requires a substantial spatial footprint and poses an overturning risk during construction in

62 steep terrain (Peila et al., 2007). Additionally, when the topography at the wall site features steep  
63 slopes, the available space behind the wall for accommodating rockfalls **is limited**.

64 In response to the challenges posed by steep terrains, narrow site conditions, and suboptimal  
65 foundation conditions in mountainous terrain, Hu et al. (2019) introduced the PSRW structure. The  
66 structures are composed of a buffer layer and an anti-slip pile-slab structure. It has found widespread  
67 application in southwestern China (Fig. 1). Due to its implementation of pile foundations, this  
68 structure possesses characteristics such as a small footprint, high interception height, and ease of  
69 construction. However, the current PSRW design verification is to treat the structure as an  
70 underground continuous wall (CAGHP, 2019). And, due to the composite nature of this structure,  
71 the dynamical response at various impact points remains ambiguous. The maximum impact energy  
72 that the structure can withstand has also not been thoroughly investigated. It can lead to potential  
73 underestimation of failure possibilities (Fig. 1d). At the same time, the existing research focuses on  
74 the single slab and pile impacted by rockfall (Wu et al., 2021; Yong et al., 2021).

**Fig. 1.** PSRW in south-western China (a) Kongyu town (b) Jiuzhaigou nature reserve (c) Zhenjiangguan tunnel exit in Chengdu-lanzhou railway (d) Wenchuan-Maerkang expressway.

75 Therefore, analysis of structural dynamic response and concrete damage is crucial to determine  
76 its effectiveness in mitigating rockfall hazards. Based on the unique advantages of the finite element

77 method, this study employs the LS-DYNA to simulate the complete process of rockfall **impacting**  
 78 **on** PSRW. This methodology has been widely adopted by numerous researchers and demonstrated  
 79 as suitable for simulating impact problems of reinforced concrete structure (Zhong et al., 2022; Fan  
 80 et al., 2022; Bi et al., 2023). In conclusion, a full-scale numerical model of a four-span pile-slab  
 81 retaining wall satisfying specification requirements is established. The rationality of the selected  
 82 material constitutive models and a numerical algorithm was validated by reproducing two physical  
 83 model tests. The structure's dynamic behavior under different impact velocities and impact centers  
 84 is discussed (Fig. 2). The results provide insights into structure dynamic response analysis of the  
 85 PSRW and serve as a benchmark for further research.

Fig. 2 Mind mapping.

## 86 2. Numerical model and validations

### 87 2.1. Model configuration

#### 88 2.1.1. Engineering background

89 The design diagram of the PSRW (Fig. 3) adheres to the Chinese **specification** for the design  
 90 of rock retaining wall engineering in geological hazards (CAGHP, 2019). The anti-slide piles with  
 91 a concrete protective layer thickness of 0.04 m have a cross-section area of 1.8 m × 1.25 m. The  
 92 total pile length is 12 m, and the embedded section is 6 m. The HRB 400 longitudinal bar with  
 93 diameters of 25 mm and 32 mm were arranged in the pile (Fig. 3c). The stirrups are HRB335 with  
 94 a diameter of 16 mm and a spacing of 200 mm. The slabs between the piles are 6 m in length, 3.5  
 95 m in width, and 0.5 m in thickness. These slabs contain two layers of 16 mm-diameter reinforced  
 96 bar. The sand buffer layer are 1 m and 5 m on top and bottom, respectively. A geogrid is horizontally

97 placed in the buffer layer at 0.25 m intervals. Lastly, 1 m<sup>3</sup> sphere rock boulder with a diameter of  
 98 1.24 m was set as an impactor. The impact locations are 2# slab center (CS) and 3# pile center (CP)  
 99 at 5.25 m over the ground.

**Fig. 3.** The design diagram of PSRW (a) front view (unit: m) (b) top view (unit: m) (c) cross-section profile of pile (unit: mm).

100 2.1.2. Soil-pile interaction

101 Under the impact, the lateral deformations of the pile are greatly influenced by the plastic  
 102 behavior of the soil, particularly the soil near the pile. Given their importance and complexity, it  
 103 isn't easy to thoroughly describe soil-pile interactions. This paper calculates the pile-soil interaction  
 104 by the lateral resistance-deflection ( $p$ - $y$ ) curve method. As stated by Truong and Lehane (2018), the  
 105  $p$ - $y$  curves for square cross-section pile are utilized as

106 
$$\frac{P}{P_u} = \tanh \left[ 5.45 \left( \frac{y}{B} \right)^{0.52} \right] \quad (1)$$

107 
$$\frac{P}{S_{u\_cu}} = 10.5 \left[ 1 - 0.75 e^{-0.6z/B} \right] S_p \quad (2)$$

108 where  $P$  is the actual lateral soil resistance, kPa;  $P_u$  is the ultimate lateral soil resistance, kPa;  
109  $S_{u\_cu}$  is consolidated isotropic undrained triaxial shear strength of soil, kPa/m;  $y$  is the actual lateral  
110 soil deformation, m;  $B$  is pile width, m;  $z$  is depth below the soil surface, m;  $S_p$  is a shape correction  
111 factor.

112 According to the reference and simulated model, the  $S_{u\_cu}$  and  $S_p$  are adopted as 1.5 kPa/m and  
113 1.25, respectively. Besides, the soil is modeled by compressive inelastic springs, arranged every  
114 0.25 m along the pile height and side (Fig. 4a).

### 115 2.1.3. Numerical model and numerical simulation scheme

#### 116 (1) Numerical model

117 The numerical model of PSRW is shown in Fig. 4. The material constitutive models, unit types,  
118 physical-mechanical parameters, and parameter source for all components are listed in Table 1. The  
119 rationality of all material constitutive models and physical mechanics parameters were verified in  
120 Section 2.2. The both piles and buffer layers are fixed for the boundary conditions. Additionally,  
121 both sides of the buffer layer are blocked by infinitely rigid walls. The contact type between the  
122 rockfall, sand buffer layer and pile-slab structure were set to automatic surface-to-surface.

#### 123 (2) Numerical simulation scheme

124 According to previous research (Muraishi et al., 2005; Chau et al., 2002), angular velocity of  
125 impactor was neglected in numerical simulations, and line velocities were set as 10, 15, 20, 25, and  
126 30 m/s, corresponding to impact energies of 130, 292.5, 520, 812.5, and 1170 kJ (Table 2). The  
127 linear velocity is perpendicular to surface of the buffer layer.

Fig. 4. Numerical model of the PSRW (a) numerical model (b) reinforced bar of PSRW (unit: mm).

128

**Table 1** Material constitutive model and physical-mechanical parameters for various components of PSRW.

Items	Constrained model	Unit types	Integral methods	Density (kg/m <sup>3</sup> )	Young's modul (MPa)	Poisson's ratio
Concrete	Continue cap concrete (MAT_159) (Heng et al., 2021)	Solid element	One integration point	2450	30000	0.3
Reinforced bar	Plastic kinematic model (MAT_003) (Heng et al., 2021)	Beam element	2×2 Gauss integration	7850	204000	0.3
Sand buffer layer	Soil-foam model (MAT_063) (Bhatti and Kishi, 2010)	Solid element	One integration point	1720	100	0.3
Impactor	Rigid body (MAT_020)	Solid element	One integration point	2600	20000	0.25
Geogrid	Plastic kinematic model (MAT_003) (Lee et al., 2010)	Shell element	Belytschko-Tsay integration	1030	464	0.3

129

**Table 2** Detailed numerical simulation scheme.

Case	Impact location	Impact height (m)	Impact velocity (m/s)	Impact kinetic energy (kJ)
CP-V10	3# pile center	5.25	10	130
CP-V15			15	292.5
CP-V20			20	520
CP-V25			25	812.5
CP-V30			30	1170
CS-V10	2# slab center	5.25	10	130
CS-V15			15	292.5
CS-V20			20	520
CS-V25			25	812.5
CS-V30			30	1170

130

Note: CP denotes the 3# pile center as impact location; CP denotes the 2# slab center as impact location; V denotes the velocities of rockfall.

131

132

## 2.2. Model validation

133

In order to verify the rationality of the selected material constitutive model and the established numerical model. Two physical model tests from previously published papers (Heng et al., 2021; Demartino et al., 2017; Schellenberg, 2008) were selected to reproduce.

134

135

136

### 2.2.1. Failure test of RC cantilever column

137

The physical model test conducted by Demartino et al. (2017) was selected to verify the ability of constitutive model to reflect the accumulative damage for RC structures under impact loads. The model is composed of a cylindrical column with a diameter of 0.3 m and a height of 1.7 m, and a square-section concrete foundation with length of 0.9 m and height of 0.5 m. The column was reinforced with sixteen 8 mm diameter longitudinal reinforced bar and 6.5 mm diameter stirrups at 100 mm spacing. The foundation was firmly connected to the ground using four 50 mm diameter high-strength prestressed reinforced bar. The experiment involved a test truck made of Q235 steel (considered as a rigid body) (Fig. 5a). The impactor was positioned 0.4 m above the bottom of the

138

139

140

141

142

143

144

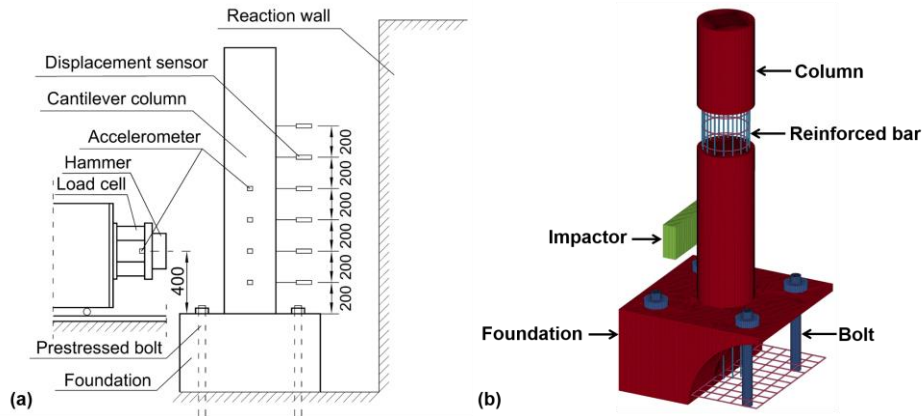

145 column and was released at a velocity of 3.02 m/s (impact energy of 7.21 kJ). Fig. 5b shows the  
 146 numerical model with hexahedral mesh. The material constitutive models for components are shown  
 147 in Table 1. For the boundary conditions, the model was fixed with four high-strength bolts.

148 The trend and amplitude of the impact forces by numerical simulations closely matched the  
 149 experimental results (Fig. 6). Similarly, Table 3 Simulation results of different mesh sizes.

Items	Impact force (kN)	Displacement of column at 1.2m height (mm)	Number of the element	Computational time (hour)
Physical model test	999.52	22.3	/	/
25 mm mesh size	966.72	23.1	5462900	24
50 mm mesh size	978.1	22	807534	4.2
100 mm mesh size	1009.35	21.3	172268	1.2

150 **Table 4** indicates a consistency between the extent of the experimental and numerical damage  
 151 in concrete. The deviations of peak impact forces between the numerical simulations and the  
 152 experiments were below 10% (Table 3). These results suggest that the numerical model and its  
 153 governing parameters can reliably simulate the accumulative damage in RC structures subjected to  
 154 impact loads. Considering both accuracy and computational time, a mesh size of 50 mm was  
 155 selected for the numerical simulations conducted in this study.

**Fig. 5.** Model of RC cantilever column failure test  
 (a) experimental model (b) numerical model (unit: mm).

**Fig. 6.** Dynamic curve of impact force with different mesh size.

156

**Table 3** Simulation results of different mesh sizes.

Items	Impact force (kN)	Displacement of column at 1.2m height (mm)	Number of the element	Computational time (hour)
Physical model test	999.52	22.3	/	/
25 mm mesh size	966.72	23.1	5462900	24
50 mm mesh size	978.1	22	807534	4.2
100 mm mesh size	1009.35	21.3	172268	1.2

157

**Table 4** Comparison of experimental and simulation results of concrete damage accumulation with time.

158

2.2.2. Failure test of RC slab with a buffer layer

159

The physical model test conducted by Schellenberg (2008) was selected to validate the capability of the constitutive model to reflect the interaction among the boulder, sand buffer layer, and RC structure. The specimen comprises a RC slab measuring 1.5 m × 1.5 m × 0.23 m and a sand buffer layer with 0.5 m in radius and 0.45m in thickness (Fig. 7). The slab is reinforced with one layer of reinforced bar with 12 mm diameter and a spacing of 95 mm for the lower layer. The diameter and density of the boulder are 0.8 m and 3110 kg/m<sup>3</sup>, respectively. The impact position is located at the center of the buffer layer, with an impact velocity of 5.5 m/s (impact energy of 14.4 kJ). The material constitutive models for concrete, reinforced bar, and sand buffer layer are shown in Table 1. For the Boundary conditions, the bottom of the supports was fixed.

168

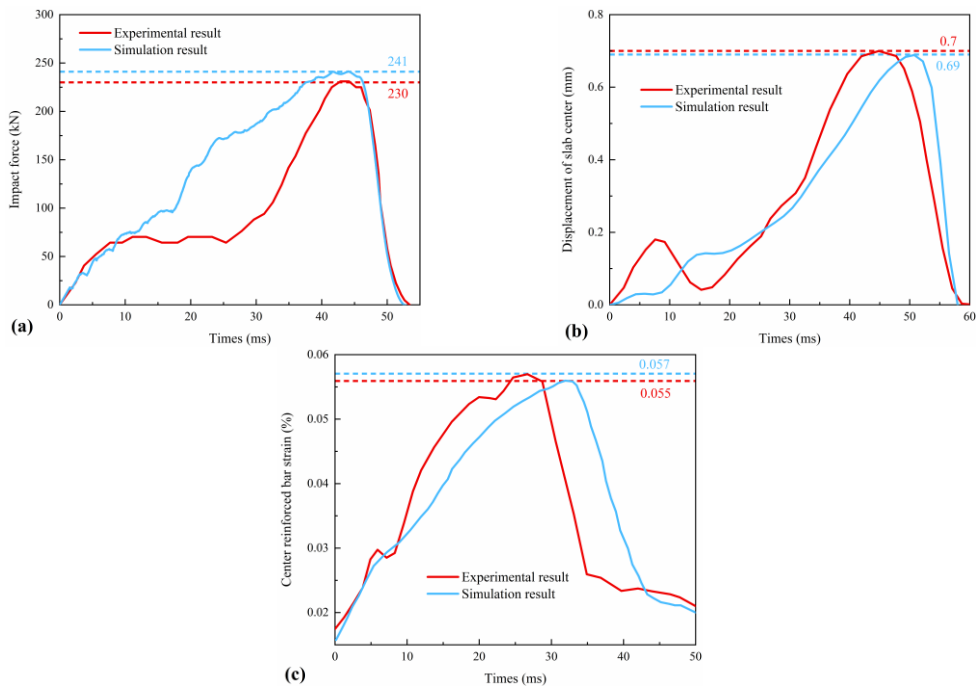

Fig. 8 presents the dynamic curve of impact force, displacement of slab center, and axial strain of center reinforced bar. The results demonstrate that the deviations of the peak impact force, the maximum strain of reinforced bar, and the slab center displacement are less than 10%. Therefore,

170

171 the numerical model and its governing parameters are deemed reliable for simulating the behavior  
 172 of a sand cushion layer and an RC structure under impact loads.

**Fig. 7.** Model of RC slab failure test  
 (a) experimental model (b) numerical model (unit: mm).

**Fig. 8.** Comparisons between experimental and simulation results  
 (a) impact force (b) displacement of slab center (c) axial strain of reinforced bar.

### 173 3. Numerical results

174 In this section, the dynamic response of PSRW under different impact centers and different  
 175 impact velocities are compared and analyzed. The main evaluation indexes are as follows: impact  
 176 force (the contact force between the impactor and the buffer layer), interaction force (the contact  
 177 force between the buffer layer and the RC structure), stress of concrete and reinforced bar, concrete  
 178 damage, lateral displacement at the crown of different components (piles and slabs), and lateral  
 179 displacement of all piles at the ground surface.

180 3.1. Influence of different impact centers

181 To analyze the influence of dynamic behaviors of PSRW under different impact centers, two  
182 group simulations under maximum impact energy (CP-V30 and CS-V30) are selected for  
183 comparison.

184 3.1.1. Impact force and interaction force

185 Fig. 9a and 9b show the dynamic curves of the impact force and interaction force, respectively.  
186 Both force curves exhibit a distinct single-peaked pattern. The impact force rapidly reduces to zero  
187 due to the energy-dissipating properties of the sand buffer layer (Fig. 9a). In contrast, the interaction  
188 force remains at a non-zero value (475 kN) (Fig. 9b). Owing to the permanent deformation sustained  
189 by the structure, and the gravitational force exerted by the sand buffer acts on the surface of the  
190 structure. Furthermore, Fig. 9a illustrates the close overlap of the impact forces for various impact  
191 centers, depending on the buffer and impactor characteristics, and minimally affected by the impact  
192 center. The slight differences observed in the dynamic curve of interaction force under CP-V30 and  
193 CS-V30 may be attributed to the flexural stiffness of the slab and pile.

194 **Fig. 9.** Dynamic curves of impact force and interaction force under various impact centers  
(a) impact force (b) interactional force.

194 3.1.2. Stress of concrete

195 The minimum principal stress of concrete and the effective stress of reinforced bar are  
196 important indexes to evaluate the dynamic response of RC structures (Zhong et al., 2021; Zhong et  
197 al., 2022). Fig. 10 shows the minimum principal stress nephogram of concrete under CP-V30 from  
198 1 to 650 ms. When  $t = 1$  ms (Fig. 10a), the minimum stress focus on the bottom of the piles. When  
199  $t = 14.7$  ms (Fig. 10b), the minimum principal stress of concrete around the impact point increased  
200 rapidly to 7.421 MPa. When  $t = 22.8$  ms (Fig. 10c), the concrete elements at the joints of the 3# pile  
201 and slabs achieve compressive strength, leading to concrete damage. When  $t = 650$  ms (Fig. 10d),  
202 the total volume of damaged elements reaches  $0.63 \text{ m}^3$ , which occupies a proportion of 0.35%.

203 Fig. 11 shows the minimum principal stress nephogram of concrete under CP-V30 from 1 to  
 204 650 ms. When  $t = 1$  ms, the maximum stress focus on the bottom of the piles (Fig. 11a). When  $t =$   
 205 14.7 ms, the minimum principal stress around the impact point increased rapidly to 12.117 MPa  
 206 (Fig. 11b). When  $t = 22.4$  ms, the elements of the concrete at the impact point of the 2# slab achieve  
 207 ultimate compressive strength, leading to the concrete damage (Fig. 11c). When  $t = 650$  ms, the total  
 208 volume of damage elements reaches  $0.61 \text{ m}^3$  (Fig. 11d), which occupies a proportion of 0.34%.

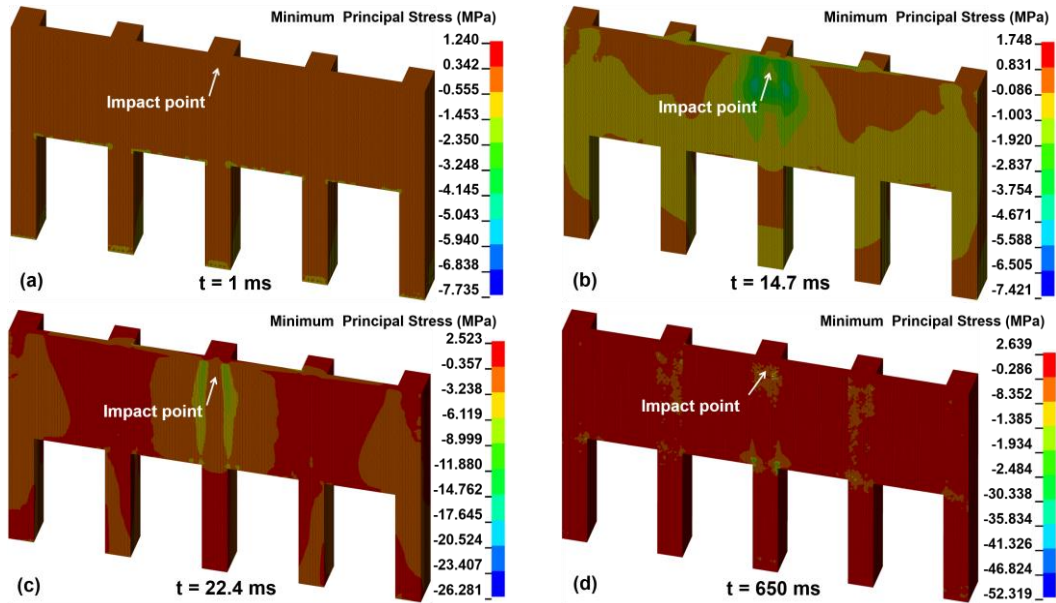

Fig. 10. Minimum principal stress nephogram of concrete under CP-V30.

209

Fig. 11. Minimum principal stress nephogram of concrete under CS-V30.

210 3.1.3. Stress of reinforced bar

211 Fig. 12 shows the effective stress nephogram of the reinforced bar from 1 to 650 ms under the  
 212 condition of CP-V30. It can be observed that: (i) when  $t = 1$  ms, the maximum stress concentrated  
 213 at the bottom of the pile (Fig. 12a); (ii) when  $t = 14.7$  ms (the moment of attaining the maximum  
 214 interaction force), the maximum stress concentrated at the vicinity of the impact point and the joints  
 215 of piles and slabs (Fig. 12c); (iii) when  $t = 650$  ms, the maximum stress concentrated at the  
 216 longitudinal bar of 2#, 3#, and 4# pile (Fig. 12d). **Noteworthy**, the effective stress of reinforced bar  
 217 did not exceed the ultimate yield stress.

218 Fig. 13 shows the effective stress nephogram of reinforced bar from 1 to 650 ms under CS-  
 219 V30. It can be observed that: (i) when  $t = 1$  ms, the maximum stress concentrated at the bottom of  
 220 the pile (Fig. 13a); (ii) when  $t = 14.7$  ms, the effective stress of reinforced bar around the impact  
 221 point increased rapidly to 137.2 MPa (Fig. 13c); (iii) when  $t = 650$  ms, the maximum stress  
 222 concentrated at the longitudinal bar of 2#, 3#, and 4# pile (Fig. 13d). **Noteworthy**, the effective  
 223 stress of reinforced bar did not exceed the ultimate yield stress.

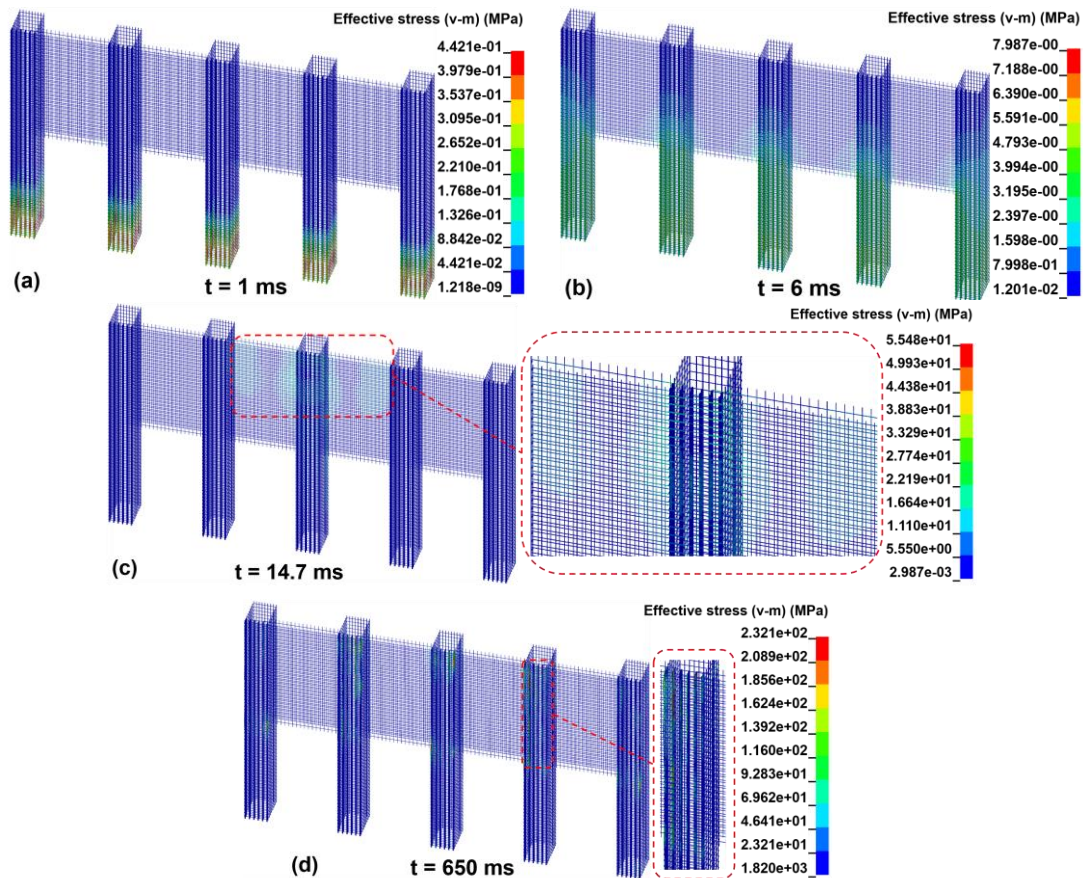

Fig. 12. Effective stress nephogram of reinforced bar under CP-V30.

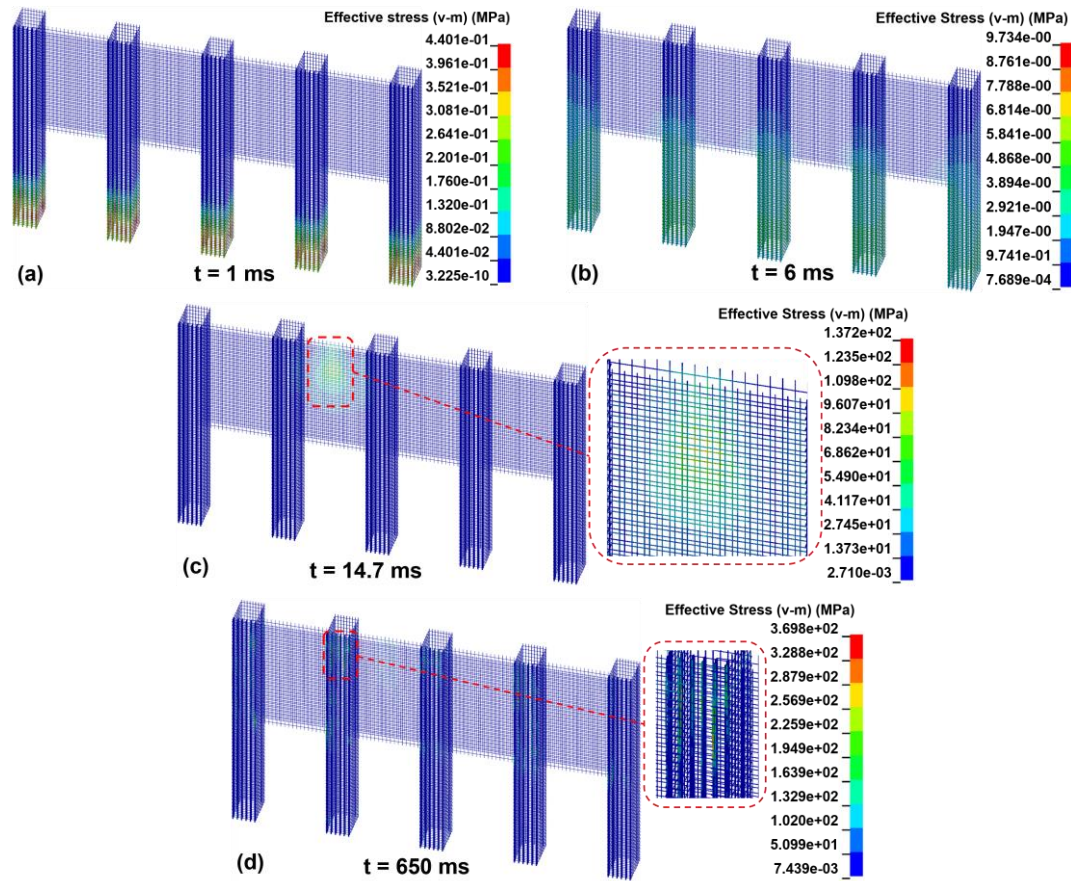

Fig. 13. Effective stress nephogram of reinforced bar under CS-V30.

224 3.1.4. Lateral displacement at the crown of different components

225 Fig. 14a presents lateral displacements at the crown of different components under CP-V30  
 226 and CS-V30 conditions. The lateral displacement rapidly increased till  $t = 177$  ms and gradually  
 227 decreased until  $t = 650$  ms. The final displacement does not reach 0, indicating plastic deformation  
 228 of both the pile and the slab. Comparing the lateral displacement under CS-V30 and CP-V30 (Fig.  
 229 14), the trends are consistent, but the magnitude differs. This discrepancy in magnitude can be  
 230 attributed to the greater deformation capacity of slab compared to pile when subjected to the same  
 231 impact energy.

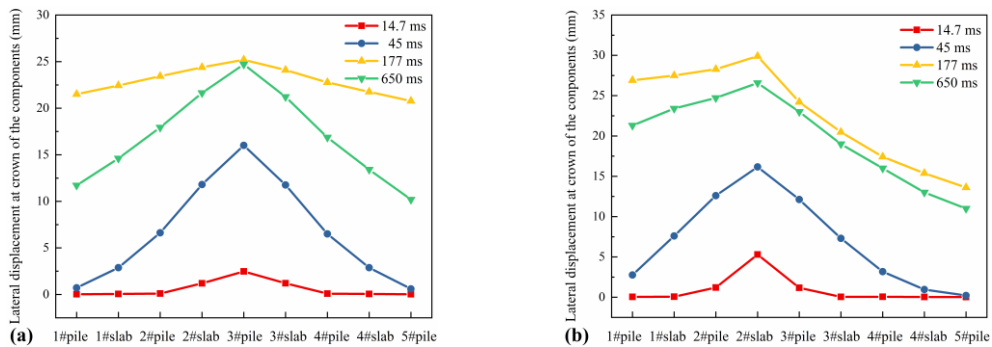

Fig. 14. Lateral displacement at crown of the components (a) CP-V30 (b) CS-V30.

232 3.1.5. Lateral displacement of piles at the ground surface

233 Fig. 15a and 16b show the dynamic curve of lateral displacement of all piles at the ground  
234 surface under CP-V30 and CS-V30, respectively. Under CP-V30, the 3# pile exhibited the  
235 maximum lateral displacement, whereas the 2# pile exhibited the maximum lateral displacement  
236 under CS-V30. This discrepancy is due to the structural asymmetry on either side of the impact  
237 center under CS-V30, which allows one side of pile #2 greater freedom, resulting in larger lateral  
238 displacement. When comparing the lateral displacement of 2# pile under CS-V30 and 3# pile under  
239 CP-V30 (Fig. 15c), it is apparent that the maximum lateral displacement of pile at the ground surface  
240 is greater under CP conditions, despite the same impact velocity. The characteristics of the lateral  
241 displacements suggest that the concrete slab is capable of undergoing larger deformations and  
242 absorbing more energy.

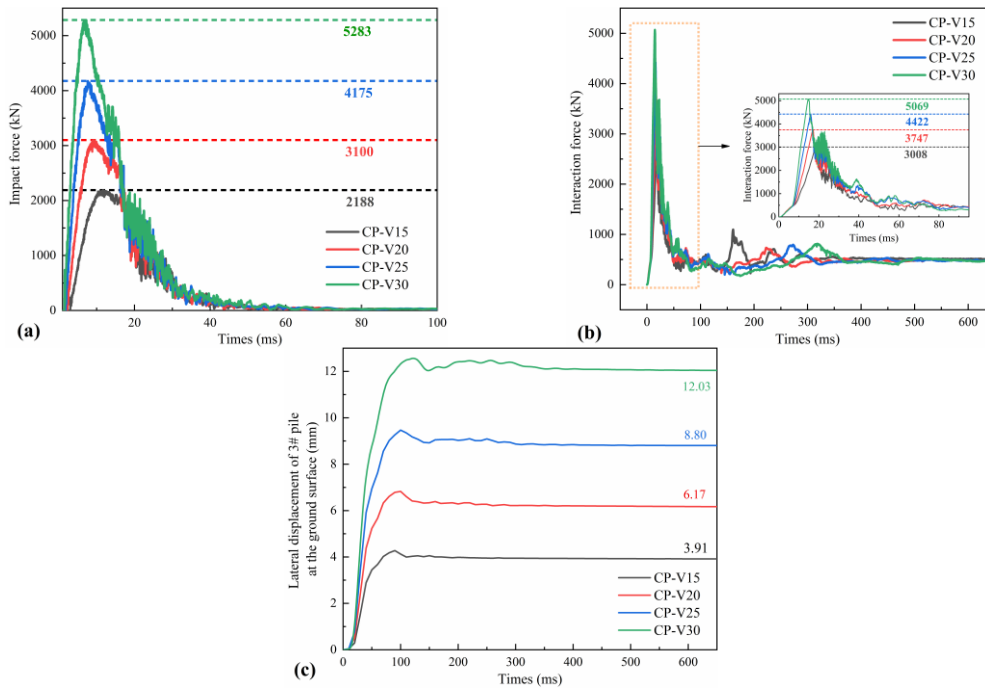

Fig. 15. Dynamic curves of lateral displacement of pile at the ground surface  
(a) CP-V30 (b) CS-V30 (c) compare between CP-V30 and CS-V30.

243 3.2. Influence of different impact velocities

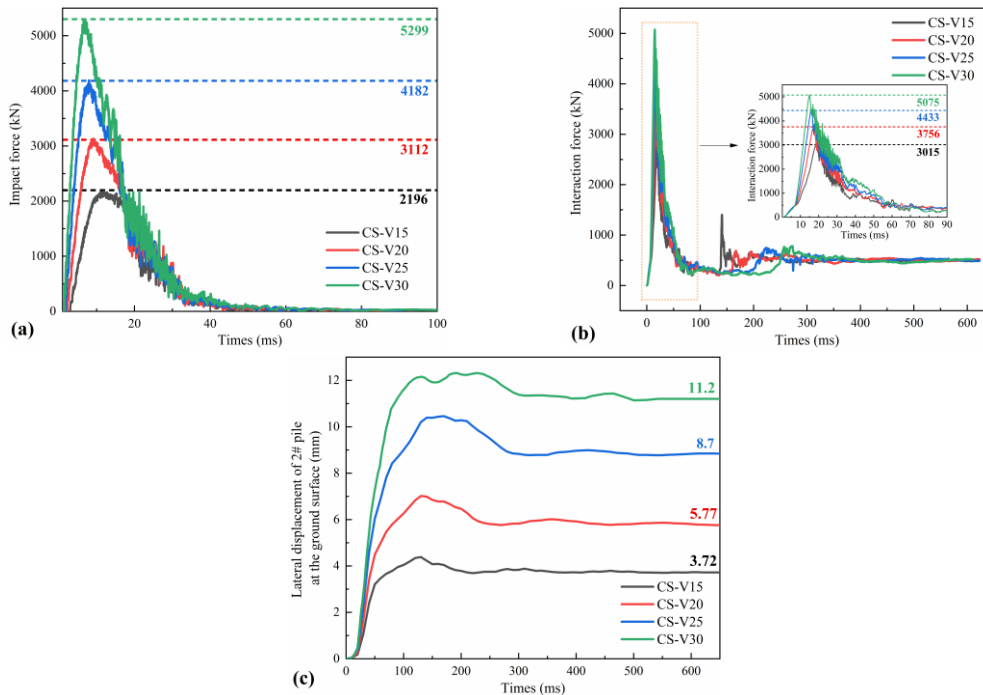

244 Figure 17 demonstrates that under CP conditions, the impact force, interaction force, and lateral  
245 displacement of pile #3 at the ground surface increase as the impact velocity of rockfall rises. When  
246 the velocity increases from 15 m/s to 30 m/s, the impact force increases by 1.42, 1.91, and 2.41  
247 times, the interaction force increases by 1.25, 1.47, and 1.68 times, and the lateral displacement of  
248 3# pile at ground surface increases by 1.57, 2.24, and 3 times at  $t = 650$  ms.

**Fig. 16.** Dynamic curves of evaluation indexes under various velocities  
 (a) impact force (b) interactional force (c) lateral displacement at the ground surface of 3# pile.

249 Fig. 17 shows the impact force, interaction force, and lateral displacement of 2# pile at the  
 250 ground surface enlarge as the impact velocity increases under CS conditions. When the velocity  
 251 increases from 15 m/s to 30 m/s, the impact force increases by 1.41, 1.90, and 2.41 times, the  
 252 interaction force increases by 1.24, 1.47, and 1.68 times, and the lateral displacement of 3# pile at  
 253 ground surface increases by 1.55, 2.23, and 3 times at  $t = 650$  ms.

**Fig. 17.** Dynamic curves of evaluation indexes under various velocities  
 (a) impact force (b) interactional force (c) lateral displacement at the ground surface of 3# pile.

254 **4. Discussions**

255 *4.1. Comparison of impact force calculation models*

256 A comparative analysis compared the elastic theories proposed by Labiouse et al. (1996),  
 257 Kawahara and Muro (2006), Pichler et al. (2006), and Hertz (1881) was conducted to assess the  
 258 validity of the numerical simulation (Fig. 18). The results reveal a fundamental linear correlation  
 259 between impact force and velocity. Overall, the computational results are consistent with those of  
 260 other models in terms of magnitude, thus confirming the validity of the calculations reported here.

**Fig. 18.** Relationship between impact velocity and impact force.

261 *4.2. Relationship between structural evaluation indexes and impact energy*

262 Table 5 lists the initial kinetic energy of impactor ( $E$ ), the peak impact force ( $F_{dm}$ ), the peak  
 263 interaction force ( $F_{im}$ ), the ratio of the peak impact force to the peak interaction force ( $\alpha$ ), the  
 264 maximum the lateral displacement of pile at the ground surface at  $t = 650$  ms ( $S_{mpt}$ ), the number of  
 265 damage failure units ( $N_d$ ), and the ratio of damage failure units to overall RC structure units ( $\beta$ ).

**Table 5** Simulation results of various impact cases.

Case	$E$ (kJ)	$F_{dm}$ (kN)	$F_{im}$ (kN)	$\alpha$ (%)	$S_{mpt}$ (mm)	$N_d$	$\beta$ (%)
CP-V10	130	1420	2170	65.4	2.25	83	0.0059
CP-V15	292.5	2188	3008	72.7	3.91	817	0.0577
CP-V20	520	3100	3747	82.7	6.17	2179	0.1539
CP-V25	812.5	4175	4422	94.4	8.8	3088	0.2181
CP-V30	1170	5283	5069	104.2	12.03	5040	0.3559

CS-V15	292.5	2196	3015	72.7	3.72	321	0.0227
CS-V20	520	3112	3756	82.7	5.77	1062	0.0750
CS-V25	812.5	4182	4433	94.4	8.7	2728	0.1927
CS-V30	1170	5299	5075	104.2	11.2	4880	0.3446

267 Under the premise of known impact energy, estimating impact force, interaction force, and  
 268 displacement of pile for the structural design is very important. As shown in Table 5, the variation  
 269 in peak impact force ( $F_{dm}$ ) with different impact centers is minimal. Consequently, CP simulation  
 270 results were chosen for further analysis. The dependence of the peak impact force on the impact  
 271 energy is shown in Fig. 19a, with a correlation coefficient  $R^2 = 0.99$ , i.e.,

272

$$F_{dm} = 3.69(E + 290.33) = 1845(mv^2 + 0.58) \quad (1)$$

273

where  $m$  is the impactor mass ( $m= 2600$  kg herein);  $v$  is the initial impact velocity ( $10$  m/s  $\leq$

274

$v \leq 30$  m/s herein).

275

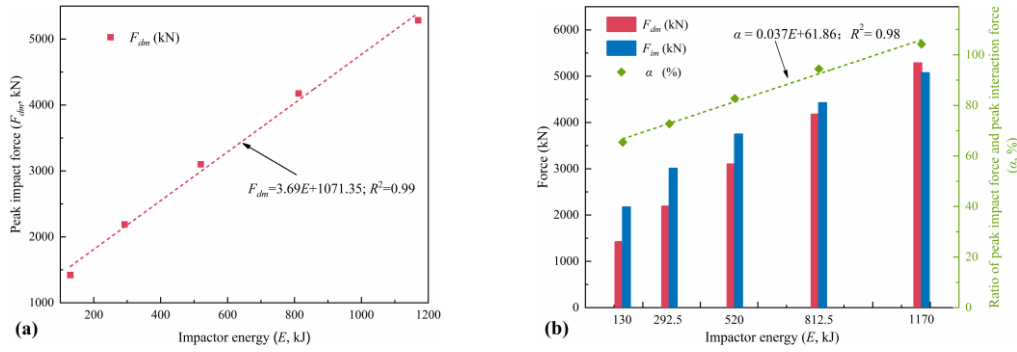

The dependence of the ratio of peak impact force to peak interaction force on the impact energy

276

is shown in Fig. 19b, with a correlation coefficient of 0.99, i.e.,

277

$$\alpha = 0.037(E + 1671.89) = 18.5(mv^2 + 3.34) \quad (2)$$

**Fig. 19.** Dependence of various indexes on impactor energy (a) peak impact force (b) the ratio of peak impact force and peak interaction force.

278

The lateral displacement of pile at the ground surface is an important index to judge the failure

279

of pile foundation under lateral load. As shown in Table 5, the maximum lateral displacement of

280

pile at the ground surface under pile as impact center is greater than that under slab as impact center.

281

Therefore, the situation where the pile is the center of impact is the more dangerous. As shown in

282

Fig. 20, with the increase of impact energy, the displacement value and number of damage failure

283

units enlarges, which means the structure suffers more damage under CP. Furthermore, the

284

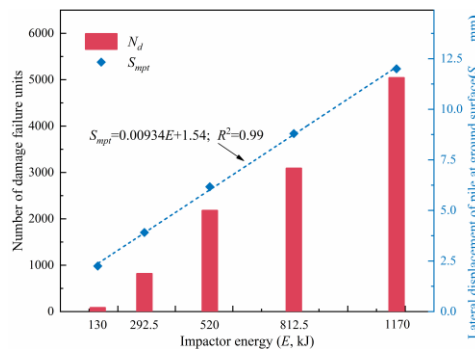

maximum lateral displacement of pile at the ground surface when  $t = 650$  ms, can be calculated by

285

the following equation:

286

$$S_{mpt} = 0.00934(E + 164.88) = 4.67(mv^2 + 0.33) \quad (3)$$

**Fig. 20.** Dependence of the lateral displacement of 3# pile at the ground surface on impactor energy

287 According to the Chinese Specification for the Design of Rock Retaining Wall Engineering in  
 288 Geological Hazards (CAGHP, 2019), the lateral displacement of the resistant sliding pile at the  
 289 ground surface must not exceed 10 mm. Substituting this value into Formula 3, the maximum impact  
 290 energy that the PSRW can withstand in this study is 905 kJ.

291 *4.3. Comparison with other concrete rockfall retaining walls*

292 Table 6 presents crucial data on an improved cast-in-place rockfall concrete barrier developed  
 293 by the US Department of Transportation (Patnaik et al., 2015). This barrier exhibits relatively low  
 294 resistance to impact energy, which restricts its applicability to situations where high-impact energy  
 295 rockfalls are likely to occur. Integrating a specialized buffering layer on the concrete retaining wall,  
 296 the barrier's impact resistance can be effectively enhanced (Kurihashi et al., 2020). According to  
 297 Maegawa et al. (2011), concrete rockfall barriers with a buffering layer offer a maximum impact  
 298 resistance ranging from approximately 120 to 490 kJ. Addressing the resistance limitations of  
 299 traditional concrete rockfall barriers, Furet et al. (2022) proposed the articulated concrete block  
 300 rockfall protection structures. These innovative structures allow concrete blocks hingedly connected  
 301 to one another, enabling greater impact energy absorption.

302 **Table 6** Comparison of different concrete rockfall protection structures

Structure name	The maximum impact energy that structure can withstand (kJ)	Energy dissipation ratio (%)	Interception altitude (m)
Cast-in-place rockfall concrete barriers (Patnaik et al., 2015)	127	/	0.81
Concrete retaining wall with buffering system (Kurihashi et al., 2020)	273	100	2.5
Concrete rock – wall (Maegawa et al., 2011)	490	/	/
Articulated concrete blocks rockfall protection structure (Furet et al., 2022)	1020	100	3.2
Pile-slab retaining wall	905	100	6

303 Note: Energy dissipation ratio denotes the ratio of dissipated energy to input energy.

304 In terms of energy dissipation, structure damage and friction are responsible for 74% of the  
 305 impact energy dissipation, with the remaining 26% attributed to other phenomena such as  
 306 deformation of structural elements, elastic wave propagation, viscous damping, and fracturing.  
 307 Compared to conventional concrete rockfall barriers, PSRW exhibit significantly higher impact  
 308 resistance (905 kJ) and interception height (6 m). Similarly, these structures absorb all the impact  
 309 energy, preventing the impactor from rebounding.

310 For traditional RC retaining walls subjected to a 16 kJ impact energy, shear cracks develop  
 311 diagonally from the impact point, with wider spreading observed on the rear face compared to the  
 312 collision surface (Kurihashi et al., 2020). Fig. 21 illustrates the concrete damage nephogram of  
 313 PSRW under the impact load of 1170 kN. It is evident that concrete damage primarily concentrated  
 314 around the impact point and at the junction between the pile and slab. Importantly, there is no  
 315 evidence of crack penetration into the structure itself, indicating that the PSRW maintains its  
 316 structural integrity.

Fig. 21. Damage nephogram of concrete at  $t = 650$  ms (a) CP-V30 (b) CS-V30.

317 Although the lateral displacement of the pile exceeds the stipulated limit, reaching 12mm as  
 318 indicated in Table 5 and Figure 21, it is essential to recognize that the specified ultimate lateral  
 319 displacement is often a conservative estimate. Concurrently, the maximum lateral displacement at  
 320 the crown of the cantilever section is 35 mm, which is substantially less than the lateral displacement  
 321 threshold for the cantilever section of the anti-slide pile. This threshold is defined as 1% of the  
 322 cantilever section's length, according to CAGHP (2019). As a result, the impact load does not  
 323 compromise the integrity of the structure.

324 In summary, the PSRW is an innovative rockfall protection structure, providing an enhanced  
 325 level of impact resistance, increased interception height, and reduced concrete damage. Additionally,  
 326 the minimal lateral displacement observed after impact further ensures the structural integrity and  
 327 safety in challenging terrain areas.

---

#### 328 4.4. Discussion on Engineering Practicality

329 The data presented in Table 7 reveal the distribution of rockfall energy levels across four  
330 regions that experience frequent rockfalls. It is evident from the table that substantial rockfalls with  
331 an impact energy of less than 1000 kJ occur in the Alps region. Schneider et al. (2023) utilized  
332 Doppler radar technology to monitor rockfall activity in Brienz/Brinzals, Switzerland. Their  
333 research indicated that although the volume of rockfalls ranged from 1 to 100 m<sup>3</sup>, smaller events (1  
334 m<sup>3</sup>) were significantly more prevalent. As previously mentioned, the PSRW demonstrates resistance  
335 against rockfalls with an impact energy of approximately 1000 kJ, thereby rendering it an  
336 appropriate choice for numerous small alpine rockfall scenarios. Additionally, its compact size and  
337 robust structural stability enhance its suitability for mountainous construction.

338 **Table 7** Rockfall events in different areas

Study area	Total number of rockfall events	Rockfall energy < 1000 kJ	Percentage
French Alps (Le Roy et al., 2019)	18	9	50%
Swiss Alps (Dietze et al., 2017)	37	37	100%
Along the railway in Japan (Muraishi et al., 2005)	173	158	91%
New South Wales, Australia (Spadari et al., 2013)	211	200	94%

#### 339 5. Conclusion

340 Numerical experiments of PSRW under 1 m<sup>3</sup> boulder impact were performed to  
341 comprehensively analyze the impact force, interaction force, stress of concrete and reinforced bars,  
342 concrete damage, and the lateral displacements of components. The main conclusions are as follows:

343 (1) The impact force exhibits a linear correlation with velocity. In comparison to several  
344 classical models for calculating impact force, the results obtained in this study are of the same order  
345 of magnitude as those derived from other models under analogous conditions.

346 (2) Concrete damage mainly concentrates at the joints between piles and slabs, the impact  
347 center, and the section of piles at the ground surface. To reduce structural concrete damage, these  
348 critical sections should be initially considered in structural optimization efforts.

349 (3) Under various impact center conditions, the difference of impact force and interaction force  
350 is very small. However, when the pile serves as the impact center, lateral displacement of pile at the  
351 ground surface and concrete damage are significantly greater. This indicates that having the pile as  
352 the impact center represents a more hazardous impact scenario.

---

353 (4) **Principal** structural evaluation indexes, including the impact force, the ratio of the peak  
354 impact force to the peak interaction force, and the maximum lateral displacement of the pile at the  
355 ground surface, increase with the growth of impact energy. These relationships **are instrumental for**  
356 **assessing** impact forces, interaction forces, and the lateral displacement of piles at ground surface  
357 **during the design of** PRSW structures. According to the correlation between the impact energy and  
358 lateral displacement of pile at the ground surface, the maximum impact energy that the PSRW, **which**  
359 **while satisfies the displacement requirements of Chinese specifications**, can withstand is 905 kJ  
360 when the **structure's crown** is **designated** as the impact point.

361 (5) **In comparison to existing rockfall protection structures, the PSRW exhibits superior**  
362 **stability and occupies a reduced footprint. Furthermore, this structure is capable of addressing a**  
363 **wide range of rockfall impact scenarios commonly encountered in alpine canyon regions.**
