1 **Abstract**

2 A novel method for quantifying the gross nitrification rate (GNR) in forested  
3 catchments using the triple oxygen isotopic composition ( $\Delta^{17}\text{O}$ ) of stream nitrate  
4 leached from the catchments has been proposed and applied in recent studies.  
5 However, the equations used in the calculations include the approximation that the  
6  $\Delta^{17}\text{O}$  value of nitrate consumed through assimilation or denitrification in the forested  
7 soil is equal to the  $\Delta^{17}\text{O}$  value of stream nitrate. The GNR estimated from the  $\Delta^{17}\text{O}$   
8 value of stream nitrate was more than six times the GNR in our simulated calculation  
9 for a forested catchment where the soil nitrate had  $\Delta^{17}\text{O}$  values higher than those the  
10 stream nitrate. The  $\Delta^{17}\text{O}$  values of the soil nitrate decreased with an increase in depth  
11 to that of the stream nitrate at the bottom. Most of the reported soil nitrate in forested  
12 catchments showed  $\Delta^{17}\text{O}$  values higher than those of the stream nitrate leached from  
13 the catchments. Thus, we concluded that the GNR estimated from the  $\Delta^{17}\text{O}$  value of  
14 stream nitrate in the forested catchments was, to an extent, an overestimate of the  
15 actual GNR.

16

17 **1 Introduction**

18 Nitrate ( $\text{NO}_3^-$ ) is an important nitrogen nutrient for primary production in forested  
19 ecosystems. Nitrification is the microbial process that produces  $\text{NO}_3^-$  in forested  
20 ecosystems. Thus, quantifying the nitrification rate can assist in the evaluation of the  
21 present and future states of forested ecosystems. The net nitrification rate can be  
22 estimated from an increase in  $\text{NO}_3^-$  concentration during a certain period. However,

23 the gross nitrification rate (GNR) (net nitrification rate + consumption rate of  $\text{NO}_3^-$   
24 (e.g., that assimilated by plants or decomposed through denitrification)), reflects the  
25 internal N cycling better than the net nitrification rate (Bengtsson et al., 2003),  
26 especially in forested ecosystems. Although the net nitrification rate is often  
27 negligible (Stark and Hart, 1997), the consumption rate is significant in forested  
28 ecosystems, such that the GNR often exceeds the net nitrification rate by several  
29 orders of magnitude (Verchot et al., 2001).

30 Recently, several studies have successfully estimated the GNR in water  
31 environments, such as lakes, using the  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-$ , as a conservative tracer  
32 of the mixing ratio between atmospheric nitrate ( $\text{NO}_3^-_{\text{atm}}$ ) and biologically produced  
33 nitrate ( $\text{NO}_3^-_{\text{bio}}$ ) (Tsunogai et al., 2011, 2018). The  $\text{NO}_3^-_{\text{atm}}$  is deposited in the water  
34 environment, and the  $\text{NO}_3^-_{\text{bio}}$  is produced through nitrification. The  $\text{NO}_3^-_{\text{bio}}$  always  
35 shows the  $\Delta^{17}\text{O}$  value close to 0 ‰ because its oxygen atoms are derived from either  
36 terrestrial  $\text{O}_2$  or  $\text{H}_2\text{O}$  through nitrification. Contrarily, the  $\text{NO}_3^-_{\text{atm}}$  always displays an  
37 anomalous enrichment in  $^{17}\text{O}$  with  $\Delta^{17}\text{O}$  value being approximately  $+26 \pm 3$  ‰ in  
38 Japan (Tsunogai et al., 2010, 2016; Ding et al., 2022, 2023) because of oxygen  
39 transfers from atmospheric ozone (Michalski et al., 2003; Nelson et al., 2018).  
40 Additionally,  $\Delta^{17}\text{O}$  is almost stable during “mass-dependent” isotope fractionation  
41 processes (Michalski et al., 2004; Tsunogai et al., 2016). This is because possible  
42 variations in the  $\delta^{17}\text{O}$  and  $\delta^{18}\text{O}$  values during the processes of biogeochemical isotope  
43 fractionation follow the relation of  $\delta^{17}\text{O} \approx 0.5 \delta^{18}\text{O}$ , which cancels out the variations

44 in the  $\Delta^{17}\text{O}$  value. Thus, regardless of the partial consumption through denitrification  
45 or assimilation after deposition in a water column, the  $\Delta^{17}\text{O}$  can be used as a  
46 conservative tracer of  $\text{NO}_3^-_{\text{atm}}$  to calculate the mixing ratio of  $\text{NO}_3^-_{\text{atm}}$  to total  $\text{NO}_3^-$   
47 ( $\text{NO}_3^-_{\text{atm}}/\text{NO}_3^-_{\text{total}}$ ) in a water column using the following equation:

$$48 \quad [\text{NO}_3^-_{\text{atm}}]/[\text{NO}_3^-_{\text{total}}] = [\text{NO}_3^-_{\text{atm}}]/([\text{NO}_3^-_{\text{bio}}] + [\text{NO}_3^-_{\text{atm}}]) = \Delta^{17}\text{O}/\Delta^{17}\text{O}_{\text{atm}} \quad (1)$$

49 where the  $\Delta^{17}\text{O}_{\text{atm}}$  and  $\Delta^{17}\text{O}$  denote the  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-_{\text{atm}}$  and  $\text{NO}_3^-$  dissolved in  
50 the water environment, respectively. Using the  $\text{NO}_3^-_{\text{atm}}/\text{NO}_3^-_{\text{total}}$  ratio estimated from  
51 the  $\Delta^{17}\text{O}$  value of  $\text{NO}_3^-$  in a lake water column and the deposition rate of  $\text{NO}_3^-_{\text{atm}}$  into  
52 the lake, the GNR was successfully estimated. This is because the partial consumption  
53 of  $\text{NO}_3^-$  has little influence on the  $\text{NO}_3^-_{\text{atm}}/\text{NO}_3^-_{\text{total}}$  ratio in the lake water column  
54 (Tsunogai et al., 2011, 2018).

55 In addition to application in water environments, the  $\Delta^{17}\text{O}$  method has been applied  
56 to forested catchments to determine their GNR (Fang et al., 2015; Hattori et al., 2019;  
57 Huang et al., 2020). Using the deposition flux of  $\text{NO}_3^-_{\text{atm}}$  into the catchment and the  
58 leaching flux of unprocessed  $\text{NO}_3^-_{\text{atm}}$  and  $\text{NO}_3^-_{\text{bio}}$  from streams, the GNR in a  
59 forested catchment was estimated similarly to the estimation for water environments  
60 (Fang et al., 2015). Contrary to water environments, where the  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-$  in  
61 the water layers are homogeneous in the water column due to the active vertical  
62 mixing of water and can be measured easily, it is often difficult to determine the  $\Delta^{17}\text{O}$   
63 values of  $\text{NO}_3^-$  consumed in soil layers. Consequently, past studies have  
64 approximated the values to be equal to the  $\Delta^{17}\text{O}$  value of stream  $\text{NO}_3^-$  leached from

65 forested catchments without actual observation (Fang et al., 2015, Hattori et al., 2019,  
66 Huang et al., 2020). However, such an approximation should be conducted with  
67 extreme caution, as the  $\Delta^{17}\text{O}$  values of soil  $\text{NO}_3^-$  are not always equal to those of  
68 streams (Hattori et al., 2019, Rose, 2014, Nakagawa et al., 2018). To clarify the  
69 details of the approximation and its impact on the final estimated GNR, we present an  
70 accurate relationship between the  $\Delta^{17}\text{O}$  of soil  $\text{NO}_3^-$  and the GNR, using basic isotope  
71 mass balance equations. Thereafter, we present the estimated GNR for a forested  
72 catchment whose  $\Delta^{17}\text{O}$  values of soil  $\text{NO}_3^-$  were measured. Finally, we compared the  
73 GNR estimated in this study with the GNR estimated from the  $\Delta^{17}\text{O}$  values of stream  
74  $\text{NO}_3^-$ .

75

## 76 **2 Calculation**

77 The total mass balance equation of  $\text{NO}_3^-$  including the GNR in catchments can be  
78 expressed as follows:

$$79 \text{NO}_3^-_{\text{deposition}} + \text{GNR} = \text{NO}_3^-_{\text{leaching}} + \text{NO}_3^-_{\text{uptake}} + \text{GDR} \quad (2)$$

80 where  $\text{NO}_3^-_{\text{deposition}}$ , GNR,  $\text{NO}_3^-_{\text{leaching}}$ ,  $\text{NO}_3^-_{\text{uptake}}$ , and GDR denote the deposition flux  
81 of  $\text{NO}_3^-$  into the catchment, GNR in the catchment, leaching flux of  $\text{NO}_3^-$  from the  
82 catchment, uptake rate of  $\text{NO}_3^-$  in the catchment, and gross denitrification rate in the  
83 catchment, respectively.

84 The isotope mass balance for each  $\Delta^{17}\text{O}$  value of  $\text{NO}_3^-$  in the catchment can be  
85 expressed using a similar equation:

86  $\text{NO}_3^-_{\text{deposition}} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{atm}} + \text{GNR} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{nitrification}} = \text{NO}_3^-_{\text{leaching}} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}} + \text{NO}_3^-_{\text{uptake}} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{uptake}} + \text{GDR} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{denitrification}}$  (3)

88 where  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{atm}}$ ,  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{nitrification}}$ ,  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}}$ ,  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{uptake}}$ , and  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{denitrification}}$  denote the  $\Delta^{17}\text{O}$  value of  $\text{NO}_3^-_{\text{atm}}$  deposited into the catchment, that of the  $\text{NO}_3^-_{\text{bio}}$  produced through nitrification, that of the  $\text{NO}_3^-$  leached from the catchment, that of the  $\text{NO}_3^-$  assimilated by plants and other organisms in the catchment, and that of the  $\text{NO}_3^-$  decomposed through denitrification in the catchment, respectively.

94 If the  $\Delta^{17}\text{O}$  values of the  $\text{NO}_3^-$  in the forested soil layers, where the  $\text{NO}_3^-$  was consumed through assimilation or denitrification, are equal to the  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-$  in the stream, we could obtain Eq. 4:

97  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{uptake}} = \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{denitrification}} = \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}}$  (4)

98 Consequently, by combining Eqs. 3 and 4, we could obtain Eq. 5:

99  $\text{NO}_3^-_{\text{deposition}} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{atm}} + \text{GNR} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{nitrification}} = (\text{NO}_3^-_{\text{leaching}} + \text{NO}_3^-_{\text{uptake}} + \text{GDR}) \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}}$  (5)

101 We could estimate the GNR using Eq. 6 obtained from Eqs. 2 and 5 because we can approximate the  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-_{\text{bio}}$  produced through nitrification

103 ( $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{nitrification}}$ ) to 0 (Michalski et al., 2003; Tsunogai et al., 2010):

104  $\text{GNR} = \text{NO}_3^-_{\text{deposition}} \times (\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{atm}} - \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}}) / \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}}$  (6)

105 Eq. 6 corresponds to the equations used in previous studies to quantify the GNR in  
106 the forested catchments (Eq. 4 in Fang et al., 2015; Eq. 8 in Hattori et al., 2019; Eq. 4  
107 in Huang et al., 2020).

108

### 109 **3 Results and Discussion**

110 The  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-$  in forested soil layers should be equal to those of stream  
111  $\text{NO}_3^-$ , as presented in Eq. 4 to obtain Eq. 6. While the number of simultaneous  
112 observations of the oxygen isotopes of  $\text{NO}_3^-$  in the soil and stream in a given forested  
113 catchment is limited (Hattori et al., 2019, Osaka et al., 2010, Rose, 2014, Nakagawa et  
114 al., 2018), the observations show that the oxygen isotopic ratios of soil  $\text{NO}_3^-$  mostly  
115 exceed those of stream  $\text{NO}_3^-$ . Differ from water environments, vertical mixing of  
116 water/soil is difficult in forested soil, so the  $\Delta^{17}\text{O}$  values of soil  $\text{NO}_3^-$  are often  
117 heterogeneous. For example, Hattori et al. (2019) reported that over 60 % of the soil  
118 exhibited  $\Delta^{17}\text{O}$  values significantly higher than those of stream  $\text{NO}_3^-$  determined  
119 simultaneously ( $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}} = +1$  to  $+3$  ‰). In addition, they found a decreasing  
120  $\Delta^{17}\text{O}$  trend in soil  $\text{NO}_3^-$  with depth, declining from greater than  $+20$  ‰ at the surface  
121 to less than  $+3$  ‰ at depths of 25–90 cm from the surface. A similar trend in the  
122 vertical distribution was observed in  $\delta^{18}\text{O}$  in another forested catchment, from above  
123  $+35$  ‰ at the surface soil to less than  $+10$  ‰ at depths of 30–50 cm from the soil  
124 surface (Osaka et al., 2010). In addition, most of the soil  $\text{NO}_3^-$  also exhibited  $\delta^{18}\text{O}$   
125 values higher than those of the stream  $\text{NO}_3^-$  (Osaka et al., 2010). Rose (2014)

126 monitored the horizontal distribution of the  $\Delta^{17}\text{O}$  of soil  $\text{NO}_3^-$  by randomly setting 15  
127 tension-free lysimeters at depths of 0–10 cm in a 39-ha forested catchment. They  
128 reported significantly higher  $\Delta^{17}\text{O}$  values in soil  $\text{NO}_3^-$  ( $+9.1 \pm 5.8$  ‰ on average) than  
129 those of stream  $\text{NO}_3^-$  ( $+0.5$  ‰ on average) leached from the forested catchment. As  
130 most fine roots and root biomass are concentrated in the top 10 cm of the soil in  
131 forested catchments (Jackson et al., 1996; Li et al., 2020), most uptake reactions  
132 should occur in that top 10 cm of soil. Consequently, the significant difference in the  
133  $\Delta^{17}\text{O}$  values between soil  $\text{NO}_3^-$  and stream  $\text{NO}_3^-$ , particularly in surface soil layers,  
134 implies that the estimated GNR in forested catchments obtained from Eq. 6 were  
135 inaccurate.

136 To demonstrate the impact of the differences in the  $\Delta^{17}\text{O}$  values of soil  $\text{NO}_3^-$  and  
137 stream  $\text{NO}_3^-$  on the GNR and present the problems associated with the approximation  
138 to obtain Eq. 6, we estimated the GNR of two simulated forested soils. The  $\Delta^{17}\text{O}$  of  
139 the first soil with  $\text{NO}_3^-$  decreased to the  $\Delta^{17}\text{O}$  of the stream  $\text{NO}_3^-$  (heterogeneous soil)  
140 (Figs. 1a and 1b). The second soil with  $\text{NO}_3^-$  showing the same  $\Delta^{17}\text{O}$  values as those  
141 of the stream  $\text{NO}_3^-$  (homogeneous soil) (Figs. 2a and 2b). Hattori et al. (2019)  
142 reported the  $\text{NO}_3^-$  deposition as  $7.0 \text{ kg of N ha}^{-1} \text{ y}^{-1}$ ,  $\text{NO}_3^-$  leaching as  $2.6 \text{ kg of N ha}^{-1} \text{ y}^{-1}$ ,  
143  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{atm}}$  as  $+28.0$  ‰, and  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}}$  as  $+2.2$  ‰ in the forested catchment  
144 they studied. We adopted the same values in the present calculation to simulate the  
145 same forested soil. All the symbols (e.g., GNR) used here were consistent with those  
146 of Hattori et al. (2019).

147 To estimate the GNR, we divided the forest soils into 10 layers (i.e., 10 steps) in the  
148 vertical direction. The  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-$  gradually decreased with an increase in  
149 depth, varying from +28.0 to +2.2 ‰ with a rate of  $-2.58$  ‰ for each step (Fig. 1b).  
150 Similarly, we assumed a gradual decrease with an increase in depth in the leaching  
151 flux of  $\text{NO}_3^-$ , (from 7 to 2.6 kg of N  $\text{ha}^{-1} \text{y}^{-1}$  at a rate of  $-0.44$  kg of N  $\text{ha}^{-1} \text{y}^{-1}$  per  
152 step) (Fig. 1c). This simulated the gradual net consumption of  $\text{NO}_3^-$  in accordance  
153 with water flow in forested soils. The homogeneous soil was also divided into 10  
154 layers in the vertical direction. The change in the leaching flux of  $\text{NO}_3^-$  with depth  
155 was the same as that in the heterogeneous soil (Fig. 2c), whereas the  $\Delta^{17}\text{O}$  values of  
156  $\text{NO}_3^-$  were constant at +2.2 ‰ in the layers (Fig. 2b).

157 Applying the total mass balance and isotope mass balance of  $\text{NO}_3^-$  shown in Eqs. 2  
158 and 3 to each layer, we estimated the GNR (Figs. 1e and 2e) and total consumption  
159 rate of  $\text{NO}_3^-$  (GDR + uptake) (Figs. 1d and 2d) in each layer. We assumed the  
160 following. (1) The  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-$  were constant in each layer. (2) The vertical  
161 flow of  $\text{NO}_3^-$  in the soil layers proceeded downward from the surface to the final layer  
162 (No. 10) with a uniform residence time in each layer. Finally, (3) the GNR and  
163 consumption rate of  $\text{NO}_3^-$  (GDR + uptake) was 0 in the water layer. Thereafter, by  
164 integrating the GNR determined for each layer, we estimated the total GNR in the  
165 forested catchment.

166 The GNR estimated for the catchment with the homogeneous  $\Delta^{17}\text{O}$  values in soil  
167  $\text{NO}_3^-$  was 83.6 kg of N  $\text{ha}^{-1} \text{y}^{-1}$  (Fig. 2e), which was exactly equal to that estimated

168 by Hattori et al. (2019) using Eq. 6. However, the GNR estimated for the catchment  
 169 with the heterogeneous  $\Delta^{17}\text{O}$  values in soil  $\text{NO}_3^-$  was considerably lower (13.0 kg of  
 170  $\text{N ha}^{-1} \text{y}^{-1}$ ; Fig. 1e), while the same parameters with the homogeneous  $\Delta^{17}\text{O}$  values in  
 171 soil  $\text{NO}_3^-$  were used for  $\text{NO}_3^-$  deposition,  $\text{NO}_3^-$  leaching,  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{atm}}$ , and  
 172  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}}$ . Even if the number of layers in the forested soils was increased to  
 173 20, 30, 50, 100, and 1000 to enhance the precision of the GNR simulated for the  
 174 catchment with the heterogeneous soil, the GNR was 11.4, 11.0, 10.5, 10.3, and 10.1  
 175  $\text{kg of N ha}^{-1} \text{y}^{-1}$ , respectively. Consequently, we concluded the following. (1) Past  
 176 studies estimated the GNR using Eq. 6 approximated the  $\Delta^{17}\text{O}$  values of soil  $\text{NO}_3^-$   
 177 consumed in the forested catchments were homogeneous and always equal to that of  
 178 stream  $\text{NO}_3^-$ . (2) The differences between the  $\Delta^{17}\text{O}$  values of the soil  $\text{NO}_3^-$  consumed  
 179 in a forested catchment and that of stream  $\text{NO}_3^-$  resulted in a significant deviation in  
 180 the GNR estimated using Eq. 6 from the actual GNR.

181 By combining the total mass balance and isotope mass balance shown in Eqs. 2 and  
 182 3, Eq. 7 was obtained to accurately estimate the GNR:

$$183 \text{ GNR} = \text{NO}_3^-_{\text{leaching}} - \text{NO}_3^-_{\text{deposition}} + (\text{NO}_3^-_{\text{deposition}} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{atm}} -$$

$$184 \text{NO}_3^-_{\text{leaching}} \times \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{stream}}) / \Delta^{17}\text{O}(\text{NO}_3^-)_{\text{soil}} \quad (7)$$

185 where  $\Delta^{17}\text{O}(\text{NO}_3^-)_{\text{soil}}$  denotes the “average”  $\Delta^{17}\text{O}$  of  $\text{NO}_3^-$  consumed through  
 186 assimilation or denitrification in the forested catchment. Most of the soil  $\text{NO}_3^-$   
 187 measured to date exhibited  $\Delta^{17}\text{O}$  values higher than those of stream  $\text{NO}_3^-$  leached  
 188 from the catchments (Hattori et al., 2019, Rose, 2014). Consequently, the GNR

189 estimated from stream  $\text{NO}_3^-$  using Eq. 6 exceeded the GNR estimated from soil  $\text{NO}_3^-$   
190 using Eq. 7, to an extent. Therefore, the GNR estimated from Eq. 6 was overestimated  
191 to an extent.

192 The linear variation in the leaching flux and  $\Delta^{17}\text{O}$  values of soil  $\text{NO}_3^-$  used in the  
193 simulated calculations (Fig. 1) is just one of many possible variations in forested  
194 catchments. It is impossible to determine whether the linear variation was realistic or  
195 not until the downward water flux, along with the concentration and  $\Delta^{17}\text{O}$  value of  
196  $\text{NO}_3^-$ , was determined for each soil layer. However, the simultaneous observations of  
197 the oxygen isotopes of soil  $\text{NO}_3^-$  and stream  $\text{NO}_3^-$  (Hattori et al., 2019; Osaka et al.,  
198 2010; Nakagawa et al., 2018; Rose, 2014) implied that the approximation of the  $\Delta^{17}\text{O}$   
199 values of soil  $\text{NO}_3^-$  to that of the stream  $\text{NO}_3^-$  (Fig. 2b) was unrealistic.

200 If we estimate the downward water flux at each soil layer, with the  $\text{NO}_3^-$   
201 concentration and  $\Delta^{17}\text{O}$  value of  $\text{NO}_3^-$  in each soil layer using, e.g., a tension-free  
202 lysimeter (Inoue et al., 2021), we could estimate the vertical change in the leaching  
203 flux of  $\text{NO}_3^-$  for each soil layer along with the  $\Delta^{17}\text{O}$  of soil  $\text{NO}_3^-$ . Thereafter,  
204 applying Eq. (7) to each layer, we can more accurately estimate the GNR for the  
205 forested catchment, by integrating the GNR estimated for each soil layer with a more  
206 accurate  $\text{NO}_3^-$  consumption rate of the forested catchment. Without such an  
207 observation of the distribution and leaching flux of  $\text{NO}_3^-$ , with the  $\Delta^{17}\text{O}$  values in  
208 forest soil, the GNR estimated using Eq. (6), assuming that the  $\Delta^{17}\text{O}$  values of soil

209  $\text{NO}_3^-$  are always equal to those of stream  $\text{NO}_3^-$ , should be reported with significant  
210 errors in which the possible variations in the  $\Delta^{17}\text{O}$  values of soil  $\text{NO}_3^-$  are considered.

211

#### 212 **4 Conclusion**

213 Past studies have proposed the  $\Delta^{17}\text{O}$  method for determining the GNR in forested  
214 catchments. The equations used in the calculation presuppose that the  $\Delta^{17}\text{O}$  values of  
215  $\text{NO}_3^-$  consumed in forested soils are homogeneous and equal to those of the stream  
216  $\text{NO}_3^-$ . However, in reality, the values are often heterogeneous and do not always  
217 equal those of the stream. It is essential to clarify/verify the  $\Delta^{17}\text{O}$  values of  $\text{NO}_3^-$  in  
218 forested soils and streams before applying the  $\Delta^{17}\text{O}$  values of stream  $\text{NO}_3^-$  to estimate  
219 the GNR.

220

221 *Data availability.* All data are presented in the Supplement.

222

223 *Author contributions.* WD, UT, and FN designed the study. WD and UT performed  
224 data analysis and wrote the paper.

225

226 *Competing interests.* The authors declare that they have no conflict of interest.

227

228 *Acknowledgments*

229 We thank Dr. Joel Bostic, Dr. Lucy Rose and other two anonymous referees, for  
230 their valuable remarks on an earlier version of this paper. We are grateful to the  
231 members of the Biogeochemistry Group, Nagoya University, for their valuable  
232 support throughout this study. This work was supported by a Grant-in-Aid for  
233 Scientific Research from the Ministry of Education, Culture, Sports, Science, and  
234 Technology of Japan under grant numbers 22H00561, 17H00780, 22K19846, the  
235 Grant-in-Aid for JSPS Fellows under grant number 23KJ1088, the Yanmar  
236 Environmental Sustainability Support Association, and the river fund of the river  
237 foundation, Japan. Weitian Ding would like to take this opportunity to thank the  
238 “Nagoya University Interdisciplinary Frontier Fellowship” supported by Nagoya  
239 University and JST, the establishment of university fellowships towards the creation  
240 of science technology innovation, Grant Number JPMJFS2120.
