**Abstract.** The Planetary Boundary (PB) concept has captured attention across academia and the public alike. Its unique visual representation has been key to the development of the concept and its dissemination. In this commentary, we outline three areas of concern to facilitate further enhancement in the PB concept’s visualisation. ~~Firstly~~First, the radial bar plot leads to a quadratic scaling of the effect sizes. ~~Secondly~~Second, the colour gradations denoting the risk of each boundary transgression use complex non-linear patterns, which complicates interpretation. ~~Thirdly, the~~Third, non-linearly distorted colour scales and their fading make the visual perception for people suffering from colour-vision deficiency even more challenging to impossible. ~~The~~ conjunction of quadratic effect scaling and specific colour coding may unintentionally amplify the perception of high-risk areas. We recommend a careful revision of the visual language employed in PB communication, ~~aiming to address these concerns~~. Addressing these concerns will make the PB visualisation a more accurate base for decision makers.

## 10 1 Introduction

Our planet faces multifaceted pressures, as corroborated by comprehensive reports like those from the IPCC on climate change and the IPBES on biodiversity change (IPBES, 2019; IPCC, 2023), encapsulating numerous additional human-induced Earth system changes. The Planetary Boundary (PB) concept (Rockström et al., 2009a, b) was designed as a framework that provides a unified perspective on the effects of altering various Earth system dimensions. It identifies thresholds, termed ‘Planetary  
15 Boundaries’, within which humans and other organisms can coexist sustainably, thus, ensuring the preservation of Earth’s vital life-support systems. With its clarity, the PB concept has emerged as a widely recognized tool for communicating the global change challenges of our era to decision-makers (Steffen et al., 2015). ~~Given~~However, given its broad scope, it is not surprising that the PB concept has sparked debate and controversy (Montoya et al., 2018; Rockström et al., 2018; Biermann and Kim, 2020). In response, the PB concept has seen refinements. More recent interpretations address initial omissions of interactions  
20 among boundaries (addressed in Steffen et al., 2015) and the absence of spatial mapping (introduced in Richardson et al., 2023). The remaining critiques are summarized by Tandon (2023). However, our aim here is not to critique the PB concept; for that, we redirect readers to the pertinent literature. Instead, we shift our focus to another facet that has thus far remained unaddressed in the discussion: the visual language used to communicate the PB concept.

**Figure 1.** Scaling issues inherent in the PB concept visualisation. (a) The latest representation of the planetary boundary concept as a radial bar plot, where indicators representing different boundaries are shown as wedges. The radius of the wedge represents the value of the indicator. Source: Richardson et al. (2023), extracted from the article pdf file, figure released under the Creative Commons Attribution NonCommercial License 4.0 CC BY-NC, <https://creativecommons.org/licenses/by-nc/4.0/>. (b) The area representation of the PBs as depicted in the original figure in (a). A small difference in the scaling is explained in the text. (c) Actual effect sizes as reported in Richardson et al. (2023). (d) Comparison of the reported PB values to the area shown. The scaling exhibits two distinct curves, as some PBs are divided into two segments. This leads to a halving of the value of the angle  $\theta$  and respective area.

Since its inception, the ~~Planetary-Boundary (PB-)~~PB concept has consistently featured a powerful visualization. Geere  
25 (2020) recounts an intriguing backstory. The conceptual seed for the PB concept, as described by him, was sown by Bo  
Ekman, founder of the Tällberg Foundation. Ekman envisioned the Earth as a crucial stakeholder at every negotiation ta-  
ble. This figurative idea was then scientifically articulated by Johan R ockstr om and underpinned by the first PB figure in  
Rockstr om et al. (2009b). However, it was likely the version in Rockstr om et al. (2009a), heavily revised by Wesley Fer-  
nandes, an art director with Nature, that made a striking impact, as noted by Geere (2020). This figure employs a radial  
30 bar plot, with each wedge representing a different PB and the safe operating space marked by a constant radius. Morse-  
letto (2017) conducted an in-depth analysis of this figure and concluded that it serves as a prime example of science com-  
munication, being understandable, meaningful, and engaging. This perception appears to be widely shared, as the figure  
has been reproduced and adapted extensively (~~e.g. Nash et al., 2017; Persson et al., 2022; Bachmann et al., 2023, and others~~)  
(e.g. Nash et al., 2017; Persson et al., 2022; Bachmann et al., 2023), and the concept has even been transferred to other branches  
35 of science, such as describing the dimensions of forest disturbance attributes (Turner and Seidl, 2023).

The most recent iteration by Richardson et al. (2023, as reproduced in fig. 1a) introduces a substantial extension. It adds  
~~color~~colour gradients intended to illustrate how the transgression of PBs translates into escalating risks. Also this figure  
has been showcased and replicated by numerous global news outlets, achieving vast reach. At first glance, the figure seems to  
provide an intuitive visualization of the core messages of the ~~Planetary-Boundary (PB-)~~PB concept as interpreted by Morseletto  
40 (2017). However, we contend that the current graphical representation of the PB concept and its derivatives, though visually  
compelling, may inadvertently mislead its audience. Here, we scrutinise the visualisation techniques employed in the PB  
concept and discuss potential pitfalls and enhancements. Our aim is to initiate a discussion towards developing a visualisation  
strategy in which the visual language accurately conveys the underlying scientific concepts.

## 2 Scaling of effect size

45 The figure in question (fig. 1a) presents a radial alignment. In fig. 1b, we recreate the latest figure presented in Richardson et al.  
(2023), by omitting the risk indicators that are depicted as colours. This variant focuses on the effect sizes, a uni-dimensional  
value—the distance to the centre. Tabular data of this kind would typically be represented as a bar chart, as illustrated in  
~~fig~~Fig. 1c. However, due to the radial configuration, the displayed area scales quadratically with the intended value of the  
variable:

$$50 \quad A_r = 0.5r^2\theta \propto r^2 \quad (1)$$

where  $A_r$  is the area of the wedge,  $r$  is the radius (i.e., the value of the PB indicator variable), and  $\theta$  is the angle of the wedge,  
as shown in ~~fig~~Fig. 1c. The area of the wedge is perceived as visual weight, which can cause the visual impression conveyed by  
this plot to not accurately reflect the underlying data, a distortion effect well-documented in the scientific visualisation literature  
~~-In~~(see e.g. Spence and Krizel, 1994. In chapter 2 of his seminal work, ‘The Visual Display of Quantitative Information’,  
55 Tuft (2001) addresses the general problem of visualisations where the size of the effect scales differently in the visualisation

compared to the data, advocating for representations where the size of the effect shown in graphics is proportional to the size of the effect in the data.

That the scaling is a particular issue for radial bar plots, known by various names such as ‘radial bar chart’, ‘radar graph’, ‘nightingale glyph’, ‘rose diagram’, and ‘polar-area diagram’, ~~has been apparent~~ is actually known since their inception by Florence Nightingale (Nightingale, 1858). Distinguished as a pioneer in statistical graphics (among other disciplines), Nightingale depicted deaths in British military hospitals during the Crimean War (1854-56; Cohen, 1984; Brasseur, 2005). Aware of the inherent scaling challenges, she opted for the wedge area rather than the radius to represent the effect sizes of the data (Cohen, 1984), a choice that could indicate the way for an alternative approach to visualizing the PB concept. However, the efficacy of radial charts is debatable. Waldner et al. (2019), for instance, shows that radial charts may be less intuitive for human interpretation compared to Cartesian coordinate systems, even for naturally cyclic patterns such as diurnal or seasonal events.

### 3 Scaling of colour map

The PB figure (~~fig~~Fig. 1a) is colour-coded to show the risk associated with a transgressed PB. This method is reminiscent of the different assessment reports by the IPCC, where so-called ‘burning embers’ visualise the risks from climate change for various aspects/sectors under different global warming scenarios. These ‘burning embers’ have also generated considerable attention (for a review on their development, see Zommers et al., 2020) by indicating that certain levels of global warming lead to high-risk zones in specific sectors or impact domains. However, the representation of risks by the PB figure is notably more complex, which prompts the question: why is this the case?

The colour map employed is derived from Inferno (van der Walt and Smith, 2020). Inferno is a colour-map that has been widely adopted and is considered an excellent choice for a continuous colour scale due to its visual uniformity (see ~~fig~~Fig. 2a), meaning the perceived difference between colours is proportional to the difference in the values they represent (Crameri et al., 2020). In ~~fig~~Fig. 2, we have extracted the colour gradients of the risks associated with the transgression of the PBs and displayed them against the value of the PB itself. To quantify this relationship, we have applied the following formula:

$$r = \log_e \left( \frac{x - \bar{x}_{\text{holocene}}}{x_{\text{PB}} - \bar{x}_{\text{holocene}}} + 1 \right), \quad (2)$$

to reconstruct  $r$ , the radius of the corresponding wedge in the PB visualisation by Richardson et al. (2023) as a scaling factor, where  $x$  is the PB indicator variable,  $\bar{x}_{\text{holocene}}$  is the Holocene mean of the PB indicator variable, and  $x_{\text{PB}}$  is the threshold defined as planetary boundary. This normalization places the planetary boundary at  $\log_e(2)$  and the ~~holocene~~Holocene mean

**Figure 2.** The plots show the distance of the indicator along the transgression of the PB vs. the risk as shown as distance in perceptual colourspace (CIEDE2000, Sharma et al. 2005, Sánchez Beekman 2021). (a) ~~colour~~Colour map “Inferno” as reference for a linear colour space, (b) We show the “Scale” of the colour map shown on the bottom of [figFig. 1a](#). In subplots (c) to (l) we show how the cumulative colour distance grows as a function of the change in the PB. Data has been extracted from [figFig. 1a](#).

at 0<sup>1</sup>. Values have been taken from [tabletab. 1](#) in Richardson et al. (2023)<sup>2</sup>. The *y*-axis in [figFig. 2](#) is the cumulative distance along the colour gradient in CIELAB2000 colour space (Sharma et al., 2005; Sánchez Beekman, 2021).

85 Fig. 2 shows that the risk scales for each PB in a very different manner, and the ~~nonlinearity~~non-linearity of the scaling is not comparable. For instance, the PB ‘Biosphere integrity/Genetic’ is the most overshoot boundary and the one where the high risk zone is furthest away but the yellow–red gradient still shows mostly red and very little yellow (compare [figFig. 1a](#) and [figFig. 2d](#)). In case of the PB ‘Biogeochemical flows/N’, the gradient is the one furthest in the purple high risk zone, but the yellow–red gradient is mostly yellow (compare [figFig. 1a](#) and [figFig. 2j](#)). Moreover, the transition from red to purple on  
 90 the colour scale is much more abrupt than anywhere else in the circular bar plot. Such variations in scaling are not clarified by Richardson et al. (2023). While we assume that the authors have quantified these transitions, we suggest that this form of visualising them is too subtle and does not allow the viewer to properly quantify the risk progression from the plot.

<sup>1</sup>As the viewer can see in [figFig. 1a](#) and [b](#), the ratio between the end of the wedges, the centre and the planetary boundary does not quite match the one in [figFig. 1a](#). We also set the current value of the ‘Genetics’ wedge to 110 E/MSY (extinctions per million species-years), Richardson et al. (2023) give > 100 E/MSY as a value but their figure seems to depict a value very close to 100 E/MSY, which makes this bar appear a little bit larger in [figFig. 1b](#)

<sup>2</sup>We noted that there seems to be a numerical error in the original visualisation: The pre-industrial Holocene values for blue and green water appropriation have to be either 0% (they are 9.4% and 9.8% respectively) or their wedges in the figure have to be much longer.

Two approaches to alleviate the PB visualisation issues: (a) Translating the PB figure into Cartesian coordinates and choosing a discrete colours bar – visually unattractive, but precise. The bars have been reorganized approximately by size. (b) Maintaining the circular bar chart, but scaling the wedge area by the effect sizes of the underlying variable. colours are discrete risk levels.

In the Another point that adds to the confusion is the seemingly arbitrary order of bars, in the ‘burning embers’ diagrams, the bars are arranged according to the intensity of the associated risk, which provides a clear gradient of risk, thus facilitating more straightforward visual interpretation. Conversely, the PB visualisation, ~~informative as it is,~~ lacks this arrangement and uses a highly ~~nonlinear~~ non-linear and less transparent scaling of risk, potentially complicating the visual interpretation.

From this discussion,

#### 4 Visual accessibility for colour-vision deficiency

Human colour-vision varies among individuals. Most of the population has trichromacy, meaning they possess three types of cone cells sensitive to long, medium, and short wavelengths of the light spectrum. However, some individuals have fewer functioning types of cone cells, resulting in dichromacy or monochromacy. Trichromatic colour vision is understood well to the extent where perceptual colour spaces, such as CIEDE2000 (Sharma et al., 2005), have been created (as applied, for example, in Fig. 2). Similarly, colour-vision deficiencies (CVD), or absolute colour-blindness, can now be simulated well enough to detect and prevent accessibility issues (Machado et al., 2009).

Fig. 3 presents simulations of the original PB figure as perceived by individuals with deuteranopia, protanopia, and in grey-scale (representing full colour blindness). These simulations are based on the algorithm from Brettel et al. (1997) and use code from Kovesi (2017). As is well known by graphic design and data visualisation experts, green and red hues often present readability challenges for those with CVD. Using both colours in one figure should be avoided. The colour choice in the current PB figure design is no exception. Neither individuals with deuteranopia nor those with protanopia can clearly distinguished the “Safe operating space” from the “Zone of increasing Risk” based on their colour alone.

This analysis shows that the current planetary boundaries (PB) figure, characterised by its uneven colour gradients and fading at the edges, fails to provide equal accessibility for individuals with colour vision deficiency. This is an unfortunate oversight for a scientific figure intended to inform policy-making. The importance of universally accessible colour choices, along with effortless, ready-to-use solutions, has been previously discussed, for example in Cramer et al. (2020).

#### 5 Way forward

Upon analyzing the current PB figure, two logical alternatives for visualising the PB concept emerge and ~~are presented in fig.4.~~ Option one shown in Fig. 4. The first option is choosing a Cartesian coordinate system (fig. Fig. 4a) to ~~circumvent issues of avoid issues related to~~ quadratic scaling. However, for those preferring the ~~Alternatively,~~ if a radial bar plot, ~~the practice of scaling the wedge area as~~ Nightingale demonstrated is preferred, adopting Nightingale’s approach of scaling wedge areas should be considered (fig. Fig. 4b) to rectify the scaling distortion. Additionally, substituting the continuous and ~~somewhat~~

## Colour-vision deficiency (CVD) simulations

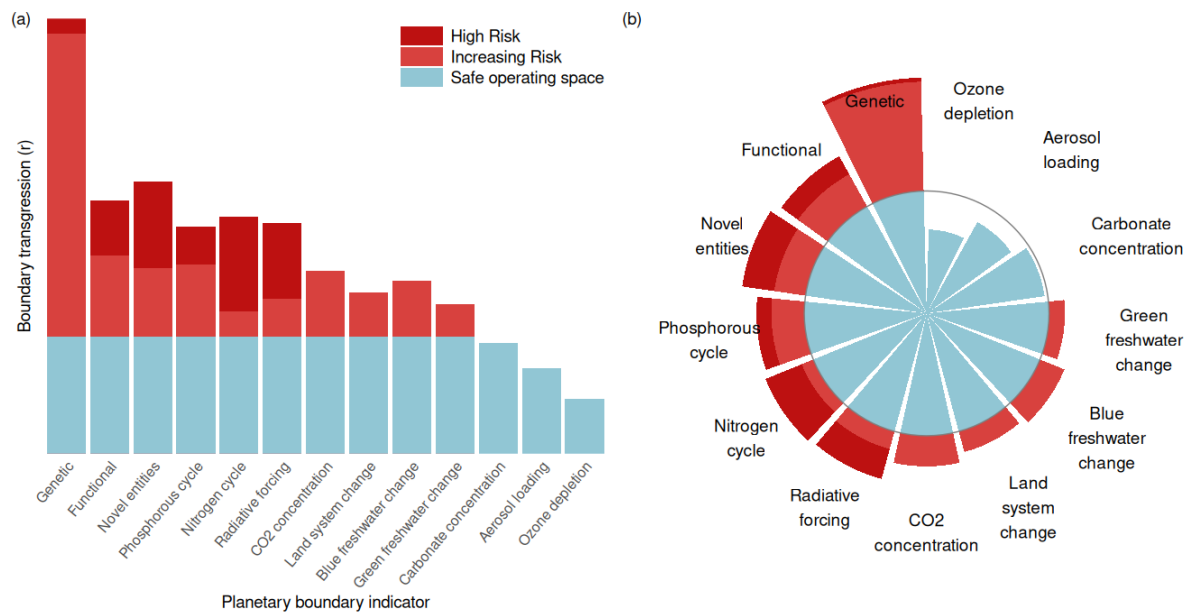

(a) Deuteranopia CVD

(b) Protanopia CVD

(c) Colour-blindness

**Figure 3.** Colour-vision deficiency simulations for (a) deuteranopia (green-blindness), (b) protanopia (red-blindness), and (c) full colour-blindness after Brettel et al. (1997) outlining how the currently applied colour coding in the PB figure is inaccessible to some readers.

**Figure 4.** Two approaches to alleviate the PB visualisation issues: (a) Translating the PB figure into Cartesian coordinates and choosing a discrete colour bar - visually unattractive, but precise. The bars have been reorganized approximately by size. (b) Maintaining the circular bar chart, but scaling the wedge area by the effect sizes of the underlying variable. Colours are discrete risk levels and the colour scale has been changed so to be accessible to readers with CVD.

complex colour scale for a discrete one yields an unambiguous visual representation. Non-conflicting discrete colours also minimize the misconception risk for people with a dichromacy or monochromacy visual perception. As stop light colour coding might be misconceived (Geere, 2020), we choose here two red colours that show the transgression region and a neutral colour for the within-boundary level.

In both alternatives, we have arranged the bars in a rough order of decreasing transgression while maintaining group cohesion. Our sketch does not depict the variable grouping. While these visualisations may not possess the artistic elegance of the original, they should convey the underlying data more precisely. Of course, ~~fig~~Fig. 4 also has limitations, such as the simplified portrayal of increasing risk and the omission of uncertainty visualisation; ~~however, these are~~. However, proposing a ready-to-use alternative figure is outside the scope of this commentary. ~~Our intent is~~ Future versions of the PB concept could, for instance, also consider incorporating interactive features to explore various future scenarios. Today, tools for interactive, web-based data analysis are ubiquitous and some are capable of handling big data (for spatiotemporal data see e.g. Söchting et al., 2023). ~~But there also many other avenues are thinkable. Our intent here is simply~~ to spark a dialogue on the visual representation of the PB concept.

## 6 Conclusions

In analysing the radial visualisation of the Planetary Boundary concept in the version published by Richardson et al. (2023), we note ~~two~~ three areas of concern. Firstly, the quadratic, area-based scaling effect may amplify the perceived transgression of PBs. Secondly, the highly ~~nonlinear~~ non-linear risk mapping functions used could potentially complicate the interpretation. Thirdly, the current planetary boundaries figure lacks visual accessibility for individuals with colour vision deficiency. Considering the interplay between area and colour perception (Solso, 1994), ~~a third issue emerges: The dark~~ an additional issue may emerge: The darker, high-risk colours might compound the quadratic effect—~~an~~ an effect that is, however, very hard to quantify. All these issues undermine the effectiveness of the PB figure in informing policy-making. Given the PB concept's aim to assist decision-makers (Steffen et al., 2015), we advocate for the development of a more precise visual language. The 'burning ember' approach (Zommers et al., 2020) presents one possible alternative. ~~Nevertheless, exploring other representations~~ Exploring other visualisation approaches, such as two-dimensional plots or an ordinal discretization of the colour scale, ~~merits further consideration~~ could also be considered.
