11 **Atmospheric Chemistry and Physics Journal**

12 **(~~March~~June 2023)**

13 **Abstract.** This study compares time series of stratospheric water vapor (SWV) data at 30 hPa
14 and 50 hPa from 1993 to 2005, based on sets of Halogen Occultation Experiment (HALOE)
15 profiles above the Boulder, CO (40°N, 255°E) region and on local frost-point hygrometer (FPH)
16 measurements. Their differing trends herein agree with most of the previously published
17 findings. ~~The~~ FPH trends are presumed to be accurate within their data uncertainties, and there
18 are no known measurement biases affecting the HALOE trends. However, the seasonal
19 sampling from HALOE is deficient at 40°N from 2001 to 2005, especially during late winter and
20 springtime. HALOE time series at 20 hPa clearly show a springtime maximum in SWV at 40°N.
21 ~~The retrievals of HALOE SWV have significant corrections for interfering aerosol extinction~~
22 ~~following the eruption of Pinatubo, but there is no evidence that those corrections cause incorrect~~
23 ~~SWV trends after 1992. Accordingly, this~~ This study finds that the SWV trends from HALOE
24 and FPH nearly agree within ~~their~~ uncertainties at 30 hPa, but not at 50 hPa, for the more limited
25 time span of 1993 to 2002. ~~HALOE SWV have significant and uncertain corrections for~~
26 ~~interfering aerosol extinction after 1992 at 50 hPa, but not at 30 hPa.~~ Northern hemisphere time
27 series and daily plots of SWV from the Limb Infrared Monitor of the Stratosphere (LIMS)
28 experiment indicate that there is transport of filaments of high SWV from polar to middle
29 latitudes during dynamically active, winter and springtime periods. Although FPH
30 measurements sense SWV variations at all scales, the HALOE time series do not resolve
31 ~~small~~ smaller-scale ~~structure~~ structures because its time series data are based on an average of four

32 or more occultations within a finite latitude/longitude sector. It is concluded that the variations
33 and trends of HALOE SWV are ~~accurate for~~reasonable at 40°N and 30 hPa from 1993 to 2002 at
34 ~~40°N~~ and in accord with the spatial scales of its measurements and ~~its~~ sampling ~~frequency over~~
35 ~~time~~frequencies.

36

37 1. Background and Objective

38 There have been numerous studies of long-term changes of stratospheric water vapor (SWV)
39 mixing ratios (e.g., Konopka, et al., 2022; Hegglin et al., 2014; Hurst et al., 2011). SWV trends
40 in the lowermost stratosphere are affected mainly by non-zonal variations of the cold-point
41 temperature (CPT) at the tropical tropopause, followed by transport of the associated relatively
42 dry, entry-level air. Hegglin et al. (2014) also report on the roles of the oxidation of methane to
43 water vapor in the middle and upper stratosphere and of changes in the Brewer/Dobson
44 circulation (BDC) on water vapor trends throughout the stratosphere. One remaining puzzle is
45 that the SWV trends from frost-point hygrometer (FPH) measurements above Boulder, CO, are
46 more positive (or less negative) than zonal average and Boulder region analyses of SWV from
47 the Halogen Occultation Experiment (HALOE), ~~and those differences increase with altitude~~
48 (Scherer et al., 2008). Lossow et al. (2018) reported that those differences increase with altitude,
49 and they cautioned that ~~the~~ trends over Boulder may not be representative of zonal-mean values,
50 ~~and some years~~. Konopka et al. (2022) found from reanalysis data that there is a moistening
51 above the Boulder region during late boreal winter and spring.

52

53 The present study reconsiders in Section 2 the HALOE SWV trends and variations ~~at 30 hPa~~
54 ~~from HALOE measurements~~ near Boulder for 1993 through 2005 and compares them in Section
55 3 with those from the Boulder FPH measurements that are assumed to be accurate. ~~Section 4~~
56 ~~considers whether there is any bias for the HALOE SWV trends and whether there is evidence~~
57 ~~for a springtime moistening at 40°N. The focus is on the trend differences at 30 hPa, where~~
58 Lossow et al. (2018) found that they were largest. Section 4 reports on the SWV trend
59 differences for the same years at 50 hPa, or where there may be biases in HALOE SWV from its
60 corrections for interfering aerosols. Section 5 shows a time series of northern hemisphere SWV
61 near 30 hPa from the Nimbus 7 Limb Infrared Monitor of the Stratosphere (LIMS) dataset of

62 1978-1979, ~~as a diagnostic for a source of elevated SWV during springtime.~~ Daily plots of
63 LIMS geopotential height (GPH) and SWV show the effects of meridional transport of SWV to
64 40°N during a dynamically active period ~~of~~in February 1979. That example provides evidence
65 of a late winter to spring moistening in the Boulder region. There are also instances of elevated
66 SWV in the HALOE SWV-time series ~~of~~at subpolar latitudes ~~at that time of year.~~ Section 6
67 concludes that the HALOE SWV variations and trends at 40°N are understandable ~~and~~
68 ~~agree~~compared with those from FPH, given the spatial scales of their measurements ~~and~~ the
69 reduction in sampling by HALOE after 2001, and possible HALOE SWV biases from interfering
70 aerosols.

71

72 2. Time series analyses of HALOE SWV near Boulder

73 SWV time series from the HALOE dataset are analyzed by multiple linear regression (MLR)
74 techniques in the manner of Remsberg (2008) and Remsberg et al. (2018a). ~~Figure 1 shows~~
75 ~~HALOE time series data from late 1991 through 2005 for the Boulder sector plus an MLR model~~
76 ~~fit to them, after correction for autoregressive effects having a lag-1 coefficient (AR1) of 0.35.~~
77 Although HALOE began operations in October 1991, its SWV profiles are degraded in the lower
78 stratosphere in 1991 through mid-1992 because of solar tracking anomalies in the presence of the
79 very large extinction effects from Pinatubo aerosols. ~~The MLR modeling of the data in Fig. 1~~
80 ~~extends from January 1993 onward. Yet, there are indications that HALOE SWV is larger for~~
81 ~~SR than for SS from 2002 through 2005. Those apparent differences are because HALOE was~~
82 ~~turned on later following a UARS yaw maneuver and turned off a bit earlier prior to the next yaw~~
83 ~~event, to conserve power on the UARS spacecraft those years. That change in operating~~
84 ~~procedure meant that there were few to no HALOE SR measurements near 40°N during late~~
85 ~~winter and springtime after 2001. Figure 1a shows HALOE time series data from late 1991~~
86 through 2005 for the Boulder sector.

87

88 The Boulder region HALOE SWV points of Fig. 1a are for 30 hPa and are based on averages of
89 profiles within the latitude range of $40 \pm 4^\circ\text{N}$ and the longitude range of $255 \pm 35^\circ\text{E}$, since HALOE
90 seldom measured profiles at the exact location of Boulder. A rather narrow latitude range was

91 chosen for this study because there is a significant latitudinal gradient in SWV near 40°N in both
92 fall and springtime. The finite longitude range of $\pm 35^\circ$ attains four or more profiles, ~~most times,~~
93 from the SR or SS orbital crossings near Boulder, ~~most times,~~ and it is sufficient for ~~resolving~~
94 ~~any~~ ~~indicating low~~ zonal ~~wave-1 and wave-2 features in wavenumber effects on~~ the SWV field.
95 ~~The data in Fig. 1a from January 1993 onward are fit with an MLR model that corrects for~~
96 ~~effects of lag-1 autoregression (AR1) and accounts for memory between adjacent data points~~
97 ~~(Tiao et al., 1990); its AR1 coefficient is 0.35.~~ The MLR model fit to the data of January 1993
98 through 2005 (~~solid curve~~) includes constant and linear trend terms plus periodic annual (AO),
99 semiannual (SAO) and QBO-like terms, ~~where the~~. ~~The periodic~~ QBO-like term is
100 approximated as a 28-mo cycle, ~~based on a Fourier analysis of an initial time series residual~~
101 ~~after accounting for the seasonal terms.~~ The model also contains proxy terms for El
102 Niño/Southern Oscillation (ENSO) ~~forcings~~ and solar cycle flux forcings. Significant terms are
103 SAO, QBO-like, and ENSO proxy; the latter two terms account for differences from the fit of the
104 HALOE data in Fig. ~~1a~~ versus that from a simple seasonal fitting, ~~as shown in SPARC (2000,~~
105 ~~Chapter 3).~~ The ~~straight~~ ~~dashed~~ line in Fig. ~~1a~~ represents the sum of the constant term (4.84
106 ppmv) and a linear trend ~~term~~ ~~coefficient~~ of $-4.4 \pm 0.7(2\sigma) \% / 22 \pm 0.04$ ppmv/decade ~~with, having~~ a
107 confidence interval (CI) of 95% ~~or a trend of~~ $-4.5 \pm 0.6(2\sigma) \% / \text{decade}$. The SWV trend from
108 Fig. ~~1a~~ agrees closely with ~~the zonal mean trend at 31.6 hPa~~ ~~previous trends~~ from HALOE
109 ~~for data near 30 hPa in~~ the latitude range of 35°N to 45°N (Davis et al., 2016). ~~Figure 2 is the~~
110 ~~residual (data minus MLR model curve) for the fit in Fig. 1, and its variations about the mean are~~
111 ~~of order ± 0.3 ppmv;~~ ~~Lossow et al., 2018).~~

112
113 ~~Occultation time series points for Fig. 1 are not spaced regularly, so the derived MLR terms are~~
114 ~~non-orthogonal.~~ ~~However, the~~ ~~All~~ MLR term coefficients are reasonably accurate, if the seasonal
115 sampling is good. ~~Otherwise, the analyzed errors for each term become~~ ~~Yet, there are~~
116 ~~indications that HALOE SWV in Fig 1a is larger—~~ ~~for sunrise (SR) than for sunset (SS)~~
117 ~~occultations from 2002 through 2005.~~ Those differences are because HALOE was turned on
118 ~~later following a UARS yaw maneuver and turned off a bit earlier prior to the next yaw event, to~~
119 ~~conserve power on the UARS spacecraft in late 2001.~~ ~~That change in operating procedure meant~~
120 ~~that there were fewer HALOE SR measurements near 40°N during late winter and springtime~~

121 after 2001, although it remained good at lower latitudes (not shown). HALOE SWV for the
122 longitude sector of Boulder but at the higher latitude zone of $55\pm 10^\circ\text{N}$ is shown in Figure 1b,
123 where the seasonal sampling is also better compared to that at 40°N in Fig. 1a. Note that
124 HALOE SWV in Fig. 1b has rather high values in early 2002 or following stratospheric warming
125 events in the winter of 2001-2002 (Charlton and Polvani, 2007). It may be that there was also
126 transport of high SWV to 40°N at that time, but HALOE did not observe it directly.

127
128 The negative HALOE SWV trend ~~is clearer in Fig. 1a~~ is affected by the downward shift in SWV
129 values from 2002 onward, as noted by Randel et al. (2006), Scherer et al. (2008), Hegglin et al.
130 (2014), and Konopka et al. (2022) noted that there was a clear according to the decrease in SWV
131 in the tropical lower stratosphere in early 2001. They reported ~~on that there was~~ a delay in the
132 decrease of SWV at 40°N because of the slow ascent of the dry tropical air plus the subsequent
133 meridional transport and mixing of that air to middle latitudes. As also noted by Scherer et al.
134 (2008),) also noted that it is perhaps more appropriate to apply two, piecewise linear trend terms
135 for the MLR modeling of the HALOE SWV data in Fig. 1a, where there is a break point in
136 2002. Instead Thus, Figure 3c shows a separate trend analysis of HALOE SWV for the Boulder
137 sector at 40°N , but for 1993 to 2002; its average SWV value is 4.62 ppmv and its shorter trend
138 term is no longer negative but positive at 0.22 ± 0.04 ppmv/decade (or $+4.47\pm 0.87(2\sigma)$ %/decade.
139). Finally, Figure 2 is the residual (data minus MLR model curve) for the fit in Fig. 1a, and its
140 variations about the mean are of order ± 0.3 ppmv. An important test of the adequacy of the set
141 of terms in its MLR model is whether any structure remains in the residual. No periodic
142 structure is apparent in Fig. 2, even though there are clear seasonal gaps in the data series after
143 2001.

144 145 **3. Time series of FPH measurements of SWV**

146 Figure 4a is the SWV time series at 30 hPa from the FPH data at Boulder and for 1993-2005 for
147 comparison with Fig. 1a. Individual FPH profiles were interpolated vertically to obtain SWV
148 values at the 30-hPa level, and the FPH time series points are also spaced irregularly. SAO,
149 QBO, ENSO, and Linear terms from the MLR model of Fig. 4a have a significance ~~(χ^2)~~ of

150 better than 90%. The constant term is 4.70 ppmv, which is a bit less than that from the HALOE
151 series (4.8384 ppmv) but within the estimated systematic uncertainties for both measurements.
152 The FPH trend for 1993-2005 is positive or $+0.17 \pm 0.07$ ppmv/decade (or $+3.46 \pm 1.5$ (2σ)
153 %/decade), as compared to the negative trend from HALOE (-4.45 ± 0.76 (2σ) %/decade). There
154 is also a change in trend around 2002 in the FPH data of Fig. 3a, although it is not so apparent
155 because of the rather large scatter of the FPH points. Figure 53b shows the residual
156 (corresponding FPH minus MLR) analysis for the time series data of Fig. 4, 1993 to 2002, which
157 yields an average SWV of 4.62 ppmv and the FPH points exhibit more scatter compared agrees
158 with the average HALOE residual in value from Fig. 21c. The larger scatter agrees reasonably
159 with the upper limit, FPH uncertainty estimate of $\pm 10\%$ or about ± 0.5 ppmv (SPARC, 2000).
160 Accordingly, it is more difficult for FPH trend for 1993 to 2002 is $+0.32 \pm 0.6$ ppmv/decade (or
161 $+6.9 \pm 1.2$ %/decade), which is more positive than that of HALOE ($+4.7 \pm 0.7$ %/decade) but only
162 slightly outside the MLR modeling to resolve the periodic (SAO, AO, and QBO) variations from
163 FPH data, while fitting a trend term overlapping envelope (e.g., $+5.7$ versus $+5.4$ %/decade) from
164 their mutual trend uncertainties.

165
166 All data points of the FPH record are assumed to be valid and accurate to 10%, based on the
167 extensive studies reported in Hurst et al. (2023). Yet, Fig. 4 shows that FPH has high SWV
168 values of 5.8 ppmv on 22 May and 5.5 ppmv on 26 June 1996. Figure 4 shows the residual (FPH
169 minus MLR) for the time series data of Fig. 3a, where the FPH points exhibit more scatter
170 compared with the HALOE residual in Fig. 2. Data points of the FPH record are assumed to be
171 valid and accurate to $< 6\%$ or about ± 0.3 ppmv, according to the extensive studies of Hall et al.
172 (2016). The rather large scatter in Fig. 4 exceeds that uncertainty. Local FPH measurements are
173 sensitive to SWV variations across all spatial scales. Note that the structure in the FPH residual
174 of Fig. 4 is aperiodic and presumably due to small-scale atmospheric variations in some
175 instances. Accordingly, it is difficult for the MLR modeling to fit all the real structure in the
176 FPH data, and its linear trend term is not highly significant. Conversely, each individual
177 HALOE profile gives an SWV value that is an average across its tangent view path (~ 300 km)
178 and with a vertical resolution of no better than two kilometers. The HALOE time series points

179 are also based on sector averages of four or more profiles. Thus, HALOE does not resolve SWV
180 variations at small to intermediate scales.

181
182 There are high FPH SWV values in Fig. 3 on 22 May (5.8 ppmv) and on 26 June 1996 (5.5
183 ppmv), possibly due to elevated SWV in filaments of polar vortex air that were transported to
184 and remained isolated above the location of Boulder for days to weeks (e.g., Manney et al. (
185 2022)). A search of individual profiles from HALOE reveals SWV values of order 6.5 ppmv at
186 60°N, 270°E in mid-March 1996. Temperature at that higher latitude location is only 200 K and
187 methane is only 0.4 ppmv, both of which are characteristic of winter vortex air. HALOE also
188 found a small region of high SWV (~5.8 ppmv) and low methane in several soundings near
189 44°N, 170°E on 12 May 1996. In another instance, FPH has a value of 5.9 ppmv high SWV on
190 12 April 2000. (5.9 ppmv). HALOE SWV approached 7.0 ppmv near 60°N, 270°E about a
191 month earlier on 18 March 2000; there are also several values greater than 5.0 ppmv at 40°N on
192 20 April 2000. Still, each individual HALOE profile gives SWV values that are an average
193 across its tangent view path of order 300 km and with a vertical resolution of no better than two
194 kilometers. The HALOE time series points are also based on sector averages of four or more
195 profiles, so they do not resolve SWV variations at small to intermediate scales. Conversely, the
196 local FPH measurements are sensitive to SWV variations across all spatial scales. HALOE values
197 greater than 5.0 ppmv at 40°N on 20 April 2000. An example of a source of the elevated SWV
198 is considered in Section 5.

199
200 ~~There is also a change in trend around 2002 in the FPH data of Fig. 4, although it is not so~~
201 ~~apparent because of the rather large scatter for the points of its data series. Figure 6 shows the~~
202 ~~MLR analysis of FPH data for 1993 to 2002, which yields an average SWV of 4.64 ppmv that~~
203 ~~agrees with the average value from HALOE in Fig. 3 (4.62 ppmv). The FPH trend for 1993 to~~
204 ~~2002 is $+5.8 \pm 1.2$ %/decade and agrees with that from HALOE ($+4.4 \pm 0.8$ %/decade), at least~~
205 ~~within their combined uncertainties.~~

206

207 **4. Uncertainties for the HALOE SWV trends**

208 ~~As noted in the previous section, the SWV trend at 30 hPa from FPH is more positive (+5.8~~
209 ~~%/decade) than that from HALOE (+4.4 %/decade) from 1993 to 2002, or prior to the episodic~~
210 ~~decrease of SWV from 2001.~~ Gordley et al. (2009) reported that there are no indications of an
211 instrument bias for the HALOE SWV trends. ~~However, HALOE SWV profiles may be affected~~
212 ~~by residual effects from cloud tops and subvisible cirrus, as shown for HALOE ozone (Bhatt et~~
213 ~~al., 1999).~~ As a result, the HALOE SWV trends at pressure levels of 100 hPa and even 70 hPa
214 may not be accurate. ~~Harries et al. (1996) reported that a given HALOE~~
215 ~~SWV profile is uncertain by 8% at 40 hPa because of interfering aerosols, and Hervig et al.~~
216 ~~(1995) made significant~~ aerosol corrections for the retrieval of HALOE SWV ~~in the lower~~
217 ~~stratosphere at 30 hPa and, especially at 50 hPa, following the Pinatubo eruption. Figure 5 is the~~
218 ~~HALOE time series at 50 hPa; note that the abrupt decrease of SWV occurs in mid-2001. While~~
219 ~~the HALOE trend is negative from 1993 to 2005, the MLR model fit is positive from December~~
220 ~~1992 to mid-2001. Its SAO, AO, QBO, and ENSO terms are significant, its mean value is 4.28~~
221 ~~ppmv, and its trend to mid-2001 is +3.7±1.4 %/decade.~~

222
223 ~~Figure 6 is the~~ ~~Harries et al. (1996)~~ ~~estimated that a given HALOE SWV profile is uncertain by~~
224 ~~6% to 8% at 10 hPa and 40 hPa, respectively, due to aerosols. Yet, the corrections are relatively~~
225 ~~accurate with time because each individual SWV profile makes use of a corresponding estimate~~
226 ~~of FPH time series at 50 hPa. It shows no clear change in 2001, largely a consequence of the~~
227 ~~scatter in the data. Its mean value from late 1992 to mid-2001 is 4.21 ppmv, but its trend is~~
228 ~~+10.8±1.7 %/decade or much larger than from HALOE. The HALOE versus FPH trend~~
229 ~~difference at 50 hPa is qualitatively like that from Scherer et al. (2008, their Fig. 7). On the other~~
230 ~~hand, at 30 hPa HALOE has lower aerosol extinction from another HALOE channel of the same~~
231 ~~occultation sounding values and yields a SWV trend for 1993 to 2002 that agrees more nearly~~
232 ~~with that of FPH (HALOE from Fig. 1c is +4.7 %/decade and FPH from Fig. 3b is +6.9~~
233 ~~%/decade).~~

234
235 ~~Corrections to SWV from interfering aerosols are more significant and extend for longer times at~~
236 ~~50 hPa than at 30 hPa.~~ Aerosol extinction profiles are determined ~~for~~ ~~from~~ wavelengths of the
237 HALOE gas filter correlation channels of HF, HCl, CH₄, and NO (Hervig et al., 1995). Then,

238 corrections for the HALOE radiometer channels (H₂O, NO₂, and O₃) are a modeled extrapolation
239 ~~is with~~ wavelength from the NO channel aerosol profile at 5.26 micrometers. Example
240 comparisons of retrieved HALOE SWV versus correlative measurements indicate that the
241 modeled corrections are qualitatively ~~accurate~~ correct, even in 1992- (~~Hervig et al., 1996~~).
242 Nevertheless, the model for aerosol absorption versus wavelength assumes a size distribution
243 shape and an aqueous sulfuric acid composition (i.e., refractive index) that is constant with
244 altitude and over time (~~Hervig et al., 1996~~). Effectively, the aerosol ~~correction~~
245 ~~represents corrections represent~~ a change in aerosol number density only. That correction model
246 ~~may not be very accurate~~ was employed for both a background aerosol layer, as well as for the
247 decay of the Pinatubo aerosol layer, as it decays over time. Thus, there ~~may~~ can be a residual,
248 time dependent bias for ~~the~~ HALOE SWV due to the aerosol correction model. Perhaps
249 HALOE SWV is under corrected at 50 hPa for the effects of aerosols through the mid-1990s.

250
251 HALOE SWV trends should be more accurate above the aerosol layer. As a check on that
252 ~~possibility~~ likelihood, Figure 7 shows the corresponding fit of the HALOE SWV time series from
253 1993 to 2002 at 40°N and 20 hPa, or just above the top of the volcanic aerosol layer. SWV has a
254 positive vertical mixing ratio gradient with altitude, due to the oxidation of methane to SWV in
255 the middle stratosphere, and average SWV at 20 hPa is 4.74 ppmv or a bit higher than that at 30
256 hPa (4.62 ppmv). A combined AO/SAO maximum shows clearly in Fig. 7, where the AO
257 amplitude is twice that of the SAO and the AO and SAO phase maxima are on 19 February and 9
258 April, respectively. Those cycles confirm the late winter/early spring moistening found in
259 reanalysis data at 40°N by Konopka et al. (2022).

260
261 The HALOE SWV trend at 20 hPa for 1993-2002 is $+6.69 \pm 0.9$ (2 σ) %/decade, which ~~is a bit~~
262 ~~higher than agrees with~~ that at 30 hPa from FPH ($+5.86.9 \pm 1.2$ %/decade) ~~at 30 hPa but within~~
263 ~~uncertainties~~. (There are too few FPH data at 20 hPa for a direct trend comparison with
264 HALOE.) ~~On the other hand~~ Yet, the HALOE trend at 20 hPa is significantly more positive than
265 ~~the HALOE's~~ its trend at 30 hPa ($+4.47 \pm 0.87$ %/decade), ~~although a positive difference is expected~~
266 ~~because of the effects of the oxidation of methane to water vapor~~. Remsberg (2015, Table 1)
267 reported significant positive trends ~~of order 10%/decade for HALOE methane~~ in the tropical

268 middle stratosphere ~~for HALOE methane of order 10%/decade~~, a small fraction (certainly less
269 than half) of which ~~has~~ may have undergone an oxidization to SWV and a subsequent transport to
270 40°N ~~and 20 hPa. Thus, the~~. The increase of 2.2%/decade ~~in~~ for the HALOE SWV trend from
271 30 to 20 hPa ~~may~~ could be ~~accounted for by those processes~~ due to that process alone. Thus, it
272 may be that the HALOE aerosol corrections ~~may be sufficiently accurate after 1992~~ at 30 hPa are
273 reasonable over time.

274

275 5. Source for the springtime moistening at 40°N

276 Hegglin et al. (2014) and Remsberg (2015) showed that both methane and water vapor from
277 limb-viewing satellite datasets (SPARC, 2017) are good indicators of seasonal variations of the
278 BDC in the stratosphere. They reported on a hemispheric asymmetry for the net circulation,
279 where the BDC in the northern hemisphere (NH) is stronger and its methane and relative SWV
280 trends are more positive than in the southern hemisphere. The strength of the NH BDC is
281 enhanced in winter, primarily due to effects of forcings from planetary waves. ~~The~~ There is
282 chemical conversion of methane to water vapor in the middle and upper stratosphere ~~is~~ followed
283 by descent of that relatively moist air to the lower stratosphere in the region of the polar vortex.

284

285 Seasonal SWV data from the LIMS experiment illustrate the above process for 1978-1979.
286 Figure 8 (from Remsberg et al., 2018b, their Fig. 14) displays ~~this~~ a seasonal increase in ~~a time~~
287 ~~series of~~ SWV ~~for~~ within the NH on the 550 K potential temperature surface (near 30 hPa) in
288 terms of its area diagnostic versus equivalent latitude, which is a vortex-centered display of
289 SWV along potential vorticity contours. Fig. 8 indicates that enhanced values of water vapor
290 descended to this surface in the vortex region by early January and continued through March.
291 Specifically, there was an equatorward expansion of the average SWV value of 5.2 ppmv to the
292 equivalent latitude of 40°N during mid-February and from mid-March onward, as the high
293 latitude air mixed with lower latitude air. Note that the 550 K surface is well above the tropical
294 tropopause, minimizing effects due to any meridional exchanges of water vapor within the
295 lowermost stratosphere. Similar analyses of seasonal changes of ozone also show that there is
296 further descent to lower potential temperature levels during springtime and a similar transport
297 and mixing of polar air to lower latitudes at those levels (Curbelo et al., 2021).

298

299 Polar plots of LIMS Version 6 (V6) geopotential height (GPH) and SWV for 17 February 1979
300 are in Figures 9 and 10. They indicate the effects of meridional transport of polar air to middle
301 latitudes, in response to a high latitude, zonal wave-2 event. Fig. 9 shows high GPH (and
302 anticyclonic circulation) in the Aleutian and eastern Atlantic sectors and low GPH in the polar
303 vortex (cyclonic) that extends southward across North America. The associated higher values of
304 SWV in Fig. 10, though somewhat noisy, are characteristic of vortex air that also underwent a
305 southward transport. The vortex (region of highest SWV) is elongated and extends equatorward
306 around 90°E and 270°E. There is also a filament of high SWV (>5.5 ppmv) at the latitude of
307 Boulder and across adjacent longitudes. The seasonal time series display of NH SWV in Fig. 8
308 shows that this is when the 5.2 ppmv contour extends to near 40°N equivalent latitude.

309

310 Figure 8 also indicates that there was an initial descent of polar air with higher values of SWV to
311 near the 31.6 hPa surface around 10 January. Then there was a more general expansion of
312 ~~elevated SWV by the end of January~~ to the equivalent latitude of 40°N ~~by the end of January~~
313 (follow the 4.8 ppmv contour in Fig. 8). Similar instances of meridional transport and mixing to
314 North American middle latitudes are a likely cause of the sporadic appearance of ~~similar~~-high
315 SWV values during the winter and early spring seasons ~~in~~of the FPH measurements ~~of~~in Fig. 43
316 and in the recent reanalysis studies of Konopka et al. (2022) and of Wargan et al. (2023).
317 However, the HALOE time series points in ~~Figs~~Fig. 1 ~~and 3~~ do not resolve such features ~~so well~~
318 because they are based on averages of four or more profiles from within the rather large sector
319 around Boulder.

320

321 HALOE SWV time series were also analyzed for occurrences of higher SWV in three separate
322 longitude sectors (North America, 255±35°E; Aleutian, 180±35°E; and European, 35±35°E)
323 from 1993 to 2002. There are several ~~such~~ instances at 40°N in the Boulder sector (Fig. 31), but
324 none in the Aleutian or European sectors (not shown). ~~However~~~~Conversely~~, Figure 11 shows
325 that there are several positive ~~SWV~~ anomalies ~~in the European sector at~~within the higher latitude
326 zone of 53±7°N, ~~while there are in the European sector but~~ none in the Boulder or Aleutian

sectors (not shown). ~~Average SWV from~~ Fig. 11 ~~is 5.14 ppmv, and SWV~~ approaches 6.0 ppmv in four instances (on 22 April 1994, 14 April 1996, 7 March 2000, and 14-19 February 2001), ~~and average SWV is 5.14 ppmv.~~ All four instances are accompanied by low values of methane, which is ~~also~~ a tracer of the transport of polar air to lower latitudes. The instances in 2000 and 2001 also occurred, ~~when just after~~ temperatures in the upper stratosphere were of order 270 K or like that for a sudden stratospheric warming (SSW) event. There was a rather extended area of higher SWV over Europe ~~at those times~~, not merely a filament of vortex air ~~following those events.~~

335

336 6. Summary and Conclusions

Analyses of time series of HALOE and FPH SWV were conducted at 30 hPa ~~and 50 hPa~~ for the Boulder region. Sampling frequencies for both ~~sets of~~ time series are ~~only~~ of the order of a ~~week~~ ~~few days~~ to ~~a month or more~~ ~~several weeks~~. The SWV trend in the Boulder region is positive from the FPH and negative from the HALOE data from 1993 to 2005. It is assumed that the time series of FPH SWV measurements are accurate, ~~at least~~ ~~or to~~ within their uncertainties of ~~$\pm 10\%$~~ ~~6%~~; the foregoing HALOE/FPH trend differences appear significant. However, there are rather large gaps at 40°N during late winter and spring in the HALOE time series after 2001, due to the limited power that was available for HALOE operations. This makes it is more difficult to resolve the seasonal terms and the trend term from ~~the HALOE time series data~~ after 2001.

346

The HALOE SWV trend goes from positive to negative around 2002, and that change is a delayed effect following the sharp decrease in tropical, lower stratospheric SWV that occurred early in 2001. The FPH time series has a trend that is less positive after 2001, too, although that change is not so obvious because of the larger scatter for its points. It is more appropriate to fit two, piecewise linear trends to both the HALOE and FPH time series with a break point in 2002.

There are no known measurement biases that are affecting the HALOE trends, ~~although~~ ~~However~~, the retrievals of HALOE SWV do have significant ~~and uncertain~~ corrections for interfering aerosol extinction following the eruption of Pinatubo. ~~However, there is no clear evidence that those corrections are affecting, particularly at 50 hPa, where the SWV trends after~~

356 ~~1992. Thus, it is concluded that the from HALOE and FPH disagree. The~~ analyzed HALOE
357 trend ~~at 30 hPa~~ (+4.47±0.87 %/decade) ~~at 30 hPa~~ agrees more closely with that from FPH
358 (~~+5.86.9±1.2 %/decade~~) ~~for 1993 to 2002 within their combined uncertainties~~, or where the
359 aerosol corrections are relatively small after 1992.

360
361 The HALOE SWV time series at 20 hPa clearly shows a springtime maximum. Northern
362 hemisphere SWV time series from the Limb Infrared Monitor of the Stratosphere (LIMS)
363 experiment indicate a transport of higher SWV from polar to middle latitudes during late winter
364 and springtime. Daily surface maps of LIMS SWV reveal ~~instances of~~ filamentary structure at
365 the latitude of 40°N during and following dynamically active periods. Surface maps of GPH
366 verify that there was meridional transport of high SWV from the polar vortex to the latitude of
367 40°N at those times. Whereas FPH measurements sense SWV variations at all scales, the
368 HALOE time series ~~of the present study~~ do not resolve intermediate to smaller scale structure
369 because its data points are based on an average of four or more occultation profiles within a
370 finite latitude/longitude sector centered on Boulder. It is concluded that the variations and trends
371 of HALOE SWV are reasonably accurate at 40°N and 30 hPa for 1993 to 2002 and in accord
372 with the spatial scales of its measurements and its sampling frequencies.
