39 40 41 A dominant term in the surface energy balance and central to global warming is downwelling longwave radiation  $(R_{td})$ . It is influenced by radiative properties of the atmospheric column, in particular by greenhouse gases, water vapour, clouds and differences in atmospheric heat storage. We use the semiempirical equation derived by Brutsaert (1975) to identify the leading terms responsible for the spatiotemporal spatial-temporal climatological variations in  $R_{ld}$ . This equation requires only near-surface observations of air temperature and humidity. We first evaluated this equation and its extension by Crawford and Duchon (1999) with observations from FLUXNET, the NASA-CERES dataset, and the ERA5 reanalysis. We found a strong-temporal spatiotemporal spatial correlation between estimated R<sub>Id</sub> and the datasets above, with  $r^2$  ranging from  $\frac{0.87 \text{ to } 0.980.87 \text{ to } 0.98}{0.87 \text{ to } 0.98}$  across the datasets for clear-sky and allsky conditions. We then used the equations to show that changes in atmospheric heat storage explain more than 95% of diurnal range in R<sub>ht</sub>. Moreover, around 73% of R<sub>ht</sub> seasonal variations are led by atmospherie heat storage on a global scale, with the regional contribution increasing with latitude. Seasonal changes in the emissivity of the atmosphere play a second role, which is controlled by anomalies in cloud cover at high latitudes but dominated by water vapor changes at mid-latitude and subtropies, especially over monsoon regions. We also found that as aridity increases over region, the contributions from changes in emissivity and atmospheric heat storage tend to offset each other (40 W m<sup>-2</sup> and 20-30 W m<sup>-2</sup>, respectively), explaining the relatively small decrease in  $R_{td}$  with aridity ( (10 20) W/m<sup>-2</sup>). We then used the equations to show that changes in lower-level atmospheric heat storage explain more than 95% and around 73% of diurnal range and seasonal variations in  $R_{ld}$ , respectively, with the regional contribution decreasing with latitude. Seasonal changes in the emissivity of the atmosphere play a second role, which is controlled by anomalies in cloud cover at high latitudes but dominated by water vapor changes at mid-latitude and subtropics, especially over monsoon regions. We also found that as aridity increases over region, the contributions from changes in emissivity and lower-level atmospheric heat storage tend to offset each other  $(-40 \text{ W m}^{-2} \text{ and } 20\text{-}30 \text{ W m}^{-2}, \text{ respectively})$ , explaining the relatively small decrease in  $R_{ld}$  with aridity  $(-40 \text{ W m}^{-2} \text{ and } 20\text{-}30 \text{ W m}^{-2}, \text{ respectively})$ , (10-20) W/m<sup>-2</sup>).- These equations thus provide a solid physical basis for understanding the spatiotemporal variability of surface downwelling longwave radiation. This should help to better understand and interpret climatological changes, such as those associated with extreme events and global warming.

#### 1 Introduction

In the global mean surface energy budget, downward longwave radiation ( $R_{ld}$ ) is-dominant surface energy input the dominant energy input to surface (333 W/m<sup>2</sup> in global mean and 306 W<sup>2</sup>/m over land), contributing more than around twice as much energy as absorbed solar radiation (161 W/m<sup>2</sup> in global mean and 184 W<sup>2</sup>/m over land) (Trenberth et al. 2009, Wild et al. 2015). This dominance holds over all regions in the climatological mean, although there are some clear variations in space and time (Figs. ure 1 and S1). It is central to global warming, reflecting the greenhouse effect of the atmosphere (Held and Soden 2000), and its variations have been suggested to be the main contributor to some regional warming amplifications, such as in the Arctic (Lee et al. 2017) and the Tibetan Plateau (Su et al. 2017). Therefore, it is important to understand the main sources of variations in this surface energy balance term, which can be seen in Figure 1.

The flux of downwelling longwave radiation is influenced by the radiative properties of the entire atmospheric column, i.e., water vapour, clouds, and greenhouse gases, but also by the heat stored in the atmosphere, i.e., the temperature at which radiation is emitted back to the surface. To obtain an estimate of this flux, Brutsaert (1975) used functional expressions for the typical temperature and humidity profiles of the lower troposphere together with radiative transfer equations and semiempirical relationships of the absorptivity by water vapor, integrated these vertically, and expressed the resulting flux  $R_{ld}$  in terms of near-surface air temperature and water vapour pressure for clear-sky conditions. He thereby derived a semi-empirical equation for  $R_{ld}$  for an effective clear sky emissivity ( $\varepsilon_{cs}$ ) and the corresponding flux of downwelling longwave radiation ( $R_{ld,cs}$ ):

$$\varepsilon_{cs} = 1.24(e_a/T_a)^{1/7},$$
 (1)

$$R_{ld,cs} = \varepsilon_{cs} \sigma T_a^{4}. \tag{2}$$

where  $\sigma$  is Stefan–Boltzmann constant ( $\sigma$  = 5.67 10<sup>-8</sup> W m<sup>-2</sup> K<sup>-4</sup>),  $e_a$  is the 2m water vapor pressure (unit: millibars) and  $T_a$  is the 2m air temperature (unit: K). The latter two meteorological variables can easily be obtained or inferred from weather stations, so that the downwelling flux of longwave radiation can be estimated from weather station observations. Note that the  $\varepsilon_{CS}$  shown in equation 1 is largely insensitive to changes in  $T_a$ . As a result, emissivity does not have a direct dependence on  $T_a$ , except that higher temperature may also lead to higher values in  $e_{a_a}$ 

This equation was later extended to all-sky conditions that include the effects of cloud cover, among which Crawford and Duchon (1999) is a common extension (Alados et al. 2012; Duarte et al. 2006; Flerchinger et al. 2009). This extension diagnoses cloud cover fraction ( $f_c$ ) as the fraction of incoming solar radiation at the surface ( $R_s$ ) in relation to the potential solar radiation ( $R_{s,pot}$ ), that is, the incoming flux at the top of the atmosphere. The emissivity for all-sky conditions,  $\varepsilon$ , is then calculated as the mix of the emissivities of clear-sky conditions (Eqn. (1), weighted by the cloud-free proportion,  $(1 - f_c)$  and clouds with an emissivity of  $\varepsilon_c = 1$  (weighted by the cloud fraction  $f_c$ ). Using this emissivity, the estimation of downwelling longwave radiation is then done by

$$f_c = 1 - R_s / R_{s,pot},\tag{3}$$

$$\varepsilon = f_c + (1 - f_c)\varepsilon_{cs},\tag{4}$$

$$R_{ld} = \varepsilon \sigma T_a^{4} \tag{5}$$

Previous studies have already verified Equations 4-5 to have a very good agreement with site measurements with the R<sup>2</sup> of 0.883 and RMSE of 15.367 W/m<sup>2</sup> with the rR<sup>2</sup> of 0.883 and RMSE of 15.367 W/m<sup>2</sup> (Duarte et al. 2006; Hatfield et al. 1983), especially when the temperature is higher than 0°C (Aase and Idso 1978;

- Satterlund 1979). Other studies have worked to calibrate and modify this estimate further to different regions (Malek 1997; Sridhar and Elliott 2002).
- This expression for downwelling longwave radiation  $R_{ld}$  given by Eqn. (5) allows us to quantify the different contributions by cloud cover,  $f_c$ , water vapor concentrations,  $e_a$  (as a measure of the total water vapor content of the atmospheric column), and air temperature,  $T_a$  (as a proxy for the heat storage within the lower level atmosphere, Panwar et al. 2022as a proxy for the total atmospheric heat storage within the column). With this, we can then attribute variations in  $R_{ld}$  to their physical causes.
- 87 Here, our aim is to first evaluate this estimate for downwelling longwave radiation with current global datasets at the continental scale. These variations are illustrated using the NASA-CERES (EBAF 4.1) 88 dataset (Loeb et al., 2018; Kato et al., 2018, NASA/LARC/SD/ASDC 2017) and the NASA-CERES 89 90 Syn1deg dataset (Doelling et al., 2013, 2016) in Figure 1 and are compared to variations in solar radiation. 91 It can be seen that the climatological distribution of  $R_{ld}$  is mostly associated with latitudes, while also 92 presenting some zonal variations, e.g., across western and eastern North America. In comparison, the 93 seasonal cycle of  $R_{ld}$  is less determined by latitudes (Fig. 1b). It has a larger magnitude over land than over 94 oceans, over arid regions than humid regions, and over cold regions more than over warm ones. Although 95 studies have revealed a close correlation between the variation of  $R_{ld}$  and other factors like air temperature, 96 water vapor, and CO2 concentration (Wang and Liang 2009; Wei et al. 2021), here we go beyond correlations and rather attribute these variations to the different terms in Eqns. (1)-(5) that represent 97 98 different radiative properties affecting  $R_{ld}$ .
- 99 To figure out the dominant driver for these spatiotemporal variations, we decompose changes in  $R_{ld}$  into its 100 components: cloud cover,  $f_c$ , heat storage changes of atmosphere as reflected by 2m air temperature,  $T_a$ , 101 and air humidity,  $e_a$ , by performing the differentiation of these equations. We show that heat storage 102 changes predominantly shape the diurnal range and seasonal cycle of  $R_{ld}$ , while cloud cover variations play 103 a second role in most cases. In addition, the temporal variations of  $R_{ld}$  are less over the ocean than over 104 land, and less during winter than summer. On the other hand, the spatial variations of  $R_{id}$  from arid to humid 105 regions is relatively small, which we will show is due to a compensating effect of corresponding changes in atmospheric emissivity and heat storage. 106
- Our paper is organized as follows: After briefly describing the datasets used in our evaluation in Section 2, we first the estimate of  $R_{ld}$  from these equations at the global scale, using multiple datasets in Section 3.1. After showing that the annual-mean and large-scale variations are well captured, we then use the equations to decompose the temporal variations of  $R_{ld}$  in terms of its mean spatial and temporal variations and relate these to their causes in Section 3.2. The spatial variations of  $R_{ld}$  are then further discussed in Section 3.3 in terms of its relationship with aridity. We then close with a brief summary and broader implications.

#### 2 Datasets

113

- To test  $R_{ld}$  estimates, we use FLUXNET half-hour observations (Pastorello et al. 2020, half-hourly values,
- 115 189 sites, see Table S1 and Figure S2 for details), the NASA—CERES monthly satellite-based radiation
- dataset (Doelling et al., 2013, 2016, monthly means, covering years 2001 to 2018), and the ERA5 monthly
- reanalysis dataset (Hersbach et al. 2018, monthly means, covering years 1979 to 2021).
- For each dataset,  $T_a$ ,  $e_a$ , and  $f_c$  are needed as inputs for Eqs. (1)-(5), while  $R_{ld}$  data is used for the
- comparison. Cloud cover fe is calculated using Eq. (3) for all three datasets with incoming solar radiation
- 120 at the surface  $(R_s)$  and the potential solar radiation  $(R_{s,pool})$ . Cloud cover  $f_c$  is calculated using Eq. (3) for
- all three datasets with incoming solar radiation at the surface  $(R_s)$  and the potential solar radiation  $(R_{s,pot})$ .
- For NASA\_CERES estimation,  $T_a$  from the CPC Global Unified Temperature dataset (CPC Global Unified
- 123 Temperature) is used as temperature observation.

- 124 For all three datasets, water vapor pressure,  $e_a$ , is not directly given. It is calculated from the water vapor
- deficit (VPD, FLUXNET) or dewpoint temperature ( $T_{dew}$ , ERA5) using Monteith and Unsworth (2008): 125

$$e_a = 6.1079 \times \exp(17.269T_{dew}/(237.3 + T_{dew})),$$
 (6)

$$e_a = 6.1079 \times \exp(17.269T_a/(237.3 + T_a)) - VPD,$$
 (7)

- And the calculated  $e_a$  from ERA5 is also used in NASA\_CERES estimation. 126
- 127 For the analysis of the spatial variations of  $R_{ld}$  along water availability, we use the aridity index (AI =  $\frac{R}{LP}$ )
- (Budyko 1958; UNCOD 1977). This index is calculated using the mean annual net radiation (R) taken from 128
- 129 the NASA-CERES dataset, the mean annual net precipitation (P) taken from the CPC Global Unified
- 130 Gauge-Based Analysis of Daily Precipitation data (Chen et al. 2008 and Xie et al. 2007, CPC Global Unified
- Gauge-Based Analysis of Daily Precipitation), and a latent heat of vaporization for water of L =
- 131
- 132 2260 kJ/kg. A larger value of AI indicates stronger aridity.

#### 3 Results and discussion

133

134

#### 3.1 Comparison to observed, satellite, and reanalysis data

- We first compared the estimates of  $R_{ld}$  at a point-by-point basis separately for clear-sky and all-sky 135
- conditions using Eqns. (2) and (5), respectively. This comparison is shown in Figure 2 using FLUXNET, 136
- CERES, and ERA5 data. The estimates correlate very well with r<sup>2</sup> of 0.02 and 0.87 for clear sky and all-137
- sky conditions, respectively, and RMSE values of 18.24 and 24.56 W m<sup>-2</sup>. The slope of the linear 138
- regressions between the estimated and observed R<sub>w</sub> for FLUXNET are 1.03 and 1.02, with most data points 139
- concentrated around the 1:1 line (Figs. 2a and 2b). The estimates correlate very well with  $r^2$  of 0.92 140
- 141 and 0.87 for clear-sky and all-sky conditions, respectively, and RMSE values of 18.24 and 24.56 W m<sup>-2</sup>.
- 142 The slope of the linear regressions between the estimated and observed  $R_{ld}$  for FLUXNET are 1.03 and
- 143 1.02, with most data points being concentrated around the 1:1 line (Figs. 2a and 2b). Note that for all-sky
- conditions, the agreement is slighty less good, with a lower correlation coefficient and a larger RSME. The 144
- 145 agreement with the NASA-CERES and ERA5 datasets are even better, with higher correlation coefficients
- 146 and lower RSME.
- 147 Despite this high level of agreement of the estimates, we can see some systematic biases in the estimates
- 148 for R<sub>ld</sub>. These can be seen in Figure 3 and Figure S2, which show the spatial distribution of these biase and
- 149 their links with temperature and humidity. For clear-sky conditions, there appears to be a general
- 150 underestimation in the high latitudes and, to some extent, in arid regions (Figs. 3c and 3e). This bias can be 151
- attributed to biases in the equations used here. Brutsaert (1975) already described that for very low 152 temperatures and in arid conditions, there are better parameter values than those used in Eq. 1, with a larger
- 153 coefficient than 1.24 and a different exponent, which thus leading to an underestimation under low humidity
- 154 (Figs. 3a, S2a, S2c). Moreover, B75 has not considered the gradual increase in emissivity as temperature
- 155 decreases below freezing (Aase and Idso 1978), thus explaining the underestimation under low temperature
- (Figs. 3b, S2b, S2b). The biases seen in Figure 3 are nevertheless notably smaller than the spatial temporal 156 157
- variations shown in Figure 1, this means that these biases do not prevent us from using Brutsaert to attribute
- the causes for the seasonal variation and the spatial range of Rid-158
- The biases for all sky conditions generally share the distribution with that of clear sky conditions, with a 159
- 160 smaller magnitude (Figs. 3b, 3d and 3f), which are also small compared to the spatial temporal variations.
- 161 These can be seen in Figure 3 and Figure S3, which show the spatial distribution of these biases and their 162 variations against temperature and humidity. For clear-sky conditions, there appears to be a general
- 163 underestimation in the high latitudes and, to some extent, in arid regions (Figs. 3c and 3e). Brutsaert (1975)
- 164 already described that for very low temperatures and in arid conditions, there are better parameter values

格式化表格

设置了格式: 字体: 非倾斜

- 165 than those used in Eq. 1, with a larger coefficient than 1.24 and a different exponent. This can then, which 166 thus leading to an underestimation of Rld under low humidity (Figs. 3a, S3a, S3c). Moreover, B75 has not 167 considered the gradual increase in emissivity as temperature decreases below freezing (Aase and Idso
- 168 1978), thus explaining the underestimation under low temperature (Figs. 3b, S3b, S3b). The biases seen in 169
- Figure 3 are nevertheless notably smaller than the spatial-temporal variations shown in Figure 1. —Tthis 170 means that these biases do not prevent us from using Brutsaert to attribute the causes for the seasonal 171 variation and the spatial range of R<sub>ld</sub>.
- 172 The biases for all-sky conditions generally share the distribution with that of clear-sky conditions, with a smaller magnitude (Figs. 3b, 3d and 3f), which are also small compared to the spatial-temporal variations. 173
- 174 Overall, this evaluation shows that the expressions given by Eqns. (1) - (5) are very well suited to describe the spatiotemporal variations of  $R_{ld}$  for current climatological conditions. 175

#### 3.2 Attribution of diurnal and seasonal variations

- We next use Eqns. (1) (5) to attribute temporal variations of  $R_{ld}$  to their physical causes. To do so, we can 178
- 179 express changes  $\Delta R_{ld}$  as a function of changes in water vapor,  $\Delta e_a$ , cloud cover,  $\Delta f_c$ , and air temperature,
- 180  $\Delta T_a$ . The functional dependence is derived from the equations by differentiation and applying the chain
- rule. In a first step, we express a change  $\Delta R_{ld}$  by the partial contributions  $\Delta R_{ld,\mathcal{E}}$  and  $\Delta R_{ld,T}$ , that are due to 181
- 182 changes in emissivity,  $\Delta \varepsilon$ , and due to changes in atmospheric heat storage that are associated with a change
- 183

176 177

$$\Delta R_{ld} = \Delta R_{ld,\varepsilon} + \Delta R_{ld,T} = \frac{\partial R_{l,d}}{\partial \varepsilon} \Delta \varepsilon + \frac{\partial R_{l,d}}{\partial T_n} \Delta T_a = \sigma \overline{T_a}^4 \Delta \varepsilon + 4 \sigma \overline{\varepsilon} \overline{T_a}^3 \Delta T_a. \tag{8}$$

- 184 The 2 terms at the right side of Eq. 8 are  $\Delta R_{ld,\varepsilon}$  and  $\Delta R_{ld,T}$ , respectively.
- 185 The contribution  $\Delta R_{ld,\varepsilon}$  is further decomposed into contributions  $\Delta R_{ld,f_c}$ ,  $\Delta R_{ld,e_a}$ , and  $\Delta R_{ld,T_a}$  due to variations in clouds,  $\Delta f_c$ , air humidity,  $\Delta e_a$ , and surface temperature,  $\Delta T_a$ . We obtain: 186

$$\Delta R_{ld,\varepsilon} = \sigma \, \overline{T_a}^4 \Delta \varepsilon \approx \sigma \overline{T_a}^4 \times \frac{\partial \varepsilon}{\partial f_c} \Delta f_c + \sigma \overline{T_a}^4 \times \frac{\partial \varepsilon}{\partial e_a} \Delta e_a + \sigma \overline{T_a}^4 \times \frac{\partial \varepsilon}{\partial T_a} \Delta T_a$$

$$= \sigma \overline{T_a}^4 \times \left(1 - 1.24 \left(\frac{\overline{e_a}}{\overline{T_a}}\right)^{\frac{1}{7}}\right) \Delta f_c + \sigma \overline{T_a}^4 \times \frac{1.24}{7} \frac{\left(1 - \overline{f_c}\right)}{(\overline{e_a})^{\frac{6}{7}} (\overline{T_a})^{\frac{1}{7}}} \Delta e_a$$

$$+ \sigma \overline{T_a}^4 \times \left(-\frac{1.24}{7}\right) \times \frac{\left(1 - \overline{f_c}\right) (\overline{e_a})^{\frac{1}{7}}}{(\overline{T_a})^{\frac{8}{7}}} \times \Delta T_a)_{\overline{\phantom{a}},\overline{\phantom{a}},\overline{\phantom{a}}}$$
(9)

- 187 The 3 terms at the right side of Eq. 9 are  $\Delta R_{ld,f_c}$ ,  $\Delta R_{ld,e_a}$ , and  $\Delta R_{ld,T_a}$ , respectively.
- Note that the third term is of less magnititude compared with the other two terms (e.g. in terms of the 188 seasonal range as shown in Fig. 5f), which is hence not focused in this work. 189
- We next applied this approach to the diurnal deviations  $\Delta R_{ld}$  from the daily mean using the FLUXNET 190 191 dataset. This decomposition is shown in Figure 4 in aggregated form across the FLUXNET sites for whole
- 192 year (Fig. 4a), the Northern hemisphere summer (Fig. 4b) and winter seasons (Fig. 4c). More than 95% of
- 193 tThe diurnal variations (of about ± 20 W m<sup>-2</sup>-) are primarily caused by diurnal changes in air temperature,
- 194 while variations in emissivity play practically no role (Fig. S4).- Diurnal changes in air temperature reflect
- 195 variations in heat storage of the atmospheric boundary layer. -This is consistent with the notion that diurnal 196 variations in solar radiation over land are buffered primarily by the lower atmosphere, rather than below
- the surface as it is the case for open water bodies and the ocean (Kleidon and Renner 2017). Since most of 197

设置了格式:字体:(中文)+中文正文(宋体),英语(英国)

the stations in the FLUXNET dataset are located in the midlatitudes of the Northern hemisphere, the variations are consistently larger in summer due to the greater solar input (Fig. 4b) than in winter (Fig. 4c).

Figure 5 shows the same kind of decomposition, but for seasonal variations in  $R_{ld}$  in the NASA-CERES dataset, which is the difference between the maximum and minimum of monthly  $R_{ld}$  data-shown in Fig. S3. The aggregation to the global scale across land and ocean is also shown in Fig. S3, where the deviations are calculated as the difference of the monthly means to the annual mean. Generally, areas with relatively low annual-mean  $R_{ld}$ , e.g. the high latitude regions of North America and northeastern Eurasia, have the largest seasonal cycle (Fig. 1). The decomposition shows that this variation is mostly due to the seasonal variation in atmospheric heat storage ( $\Delta R_{td,T}$ ), with a portion of around 73% on a global scale, and the rest are attibuted to the seasonal changes in water vapor (24%) and cloud cover (12%) The decomposition shows that this variation is mostly due to the seasonal variation in atmospheric heat storage ( $\Delta R_{ld,T}$ ), with a portion of around 73% on a global scale, and the rest are attributed to the seasonal changes in water vapor (24%) and cloud cover (12%). Notebly, seasonal variations in emissivity play a greater role than atmospheric heat storage in changing  $R_{ld}$  in tropical areas, especially over the monsoon region, and this is predominantly due to seasonal fluctuations in water vapor levels (Figs. 5d 5f) Notably, seasonal variations in emissivity play a greater role than atmospheric heat storage in changing  $R_{ld}$  in tropical areas, especially over the monsoon region. , and Tthis is predominantly due to the strong seasonal fluctuations in water vapor levels - and cloudcover (Figs. 5d-5f).

The aggregation to the global scale across land and ocean is shown in Fig. S5, where the deviations are calculated as the difference of the monthly means to the annual mean. Figs. S5 show that the seasonal variations of  $R_{ld}$  is generally less over the ocean than on the land, an effect that can also be seen in Fig. 1. The decomposition shows that these variations are mostly caused by changes in lower-level atmospheric heat storage, with a slight modulation by emissivity changes. This can, again, be largely explained by the effect described above for the diurnal variations (Kleidon and Renner 2017). Over the land, the changes in radiation are majorly buffered by the heat storage in the lower atmosphere by the variations in convective boundary layer height. However, over marine areas, solar radiation penetrates the transparent water bodies, the heat storage of which hence buffers the season eyele of the radiation over the ocean. Since the heat storage of the water body is larger than that of the lower atmospheric boundary layer, the buffering effect is consequently larger, which leads to the less seasonal cycle of the surface temperature and Rid over the ocean Over the land, the changes in radiation are majorly buffered by the heat storage in the lower atmosphere by the variations in convective boundary layer height. However, over marine areas, solar radiation penetrates the transparent water bodies, the heat storage of which hence buffers the season cycle of the radiation over the ocean. Since the heat storage of the water body is larger than that of the lower atmospheric boundary layer, the buffering effect is consequently larger, which leads to the less seasonal cycle of the surface temperature and R<sub>ld</sub> over the ocean.

In summary, what our decomposition shows is that most temporal variations in  $R_{ld}$  in current, climatological conditions are explained by heat storage changes within the lower atmosphere.

Last, we applied the decomposition to the climatological variations in  $R_{ld}$  along with differences in mean water availability. -Water availability was characterized by Budyko's aridity index (AI), with values AI < 1 representing humid regions, and larger values reflecting increased aridity. The spatial distribution of AI is shown in Fig. S6The spatial distribution of AI is shown in Fig. S7. Here, the deviations  $\Delta R_{ld}$  are calculated with respect to the global-annual mean\_over land.- The different contributions to the deviations are shown in Fig. 6, as well as the delineation along the aridity index (Figs. 6e - f).

The decomposition of the spatial distribution of the climatological means shows that the variations are largely eaused by differences in atmospheric heat storage as well (Fig. 6a). The contribution due to

variations in emissivity has a much smaller magnitude (Fig. 6b), and is dominated by changes in cloud cover (Fig. 6c) and changes in water vapor (Fig. 6d) at high and mid latitudes respectively.

The decomposition of the spatial distribution of the climatological means shows that the variations are largely caused by differences in lower level atmospheric heat storage as well (Fig. 6a). The contribution due to variations in emissivity has a smaller magnitude (Fig. 6b), and is dominated by changes in cloud cover (Fig. 6c) and changes in water vapor (Fig. 6d) at high- and mid- latitudes respectively.

These variations are evaluated with respect to the aridity index in Figs. 6e, 6—f and S7. While there is a large spread, as seen in the quantiles, there is a small, but consistent trend towards lower values of  $R_{ld}$  in more arid regions, with a magnitude of about  $-10\text{--}20\,\text{W}$  m<sup>-2</sup> across the entire aridity index spectrum (black dashed line in Figs. 6e and 6f). We also notice a shift in the contributions, with emissivity contributing less and lower-level atmospheric heat storage contributing more with increased values of AI. The changes-decreasing contributions in emissivity of about  $-20\text{--}40\,\text{W}$  m<sup>-2</sup> is caused by reductions in cloud cover and water vapor (, as shown by the orange lines in Figs. 6f), and amounts to around  $-40\,\text{W}$  m<sup>-2</sup> over the range shown in the Figure 6e which. This decrease in cloud cover and water vapor can be attributed to the common presence of high-pressure systems in subtropical arid areas (Zampieri et al. 2009) and less monsoon there. The decreasing contribution by lower atmospheric emissivity is compensated for by an increased contribution of about  $+10\text{--}20\,\text{W}$  m<sup>-2</sup> by atmospheric heat storage that is caused by the generally warmer mean temperatures in arid regions.

Taken together, these trends imply that, again, the climatological variations in  $R_{la}$ -are also dominated by differences in atmospheric heat storage. A small, but consistent change can be seen in the contributions along the aridity index, with the contribution by emissivity due to cloud cover becoming lower while the contribution by atmospheric heat storage increases as regions become drier.

#### 4. Discussion and Conclusions

We found that the semiempirical equations of Brutsaert (1975) and Crawford and Duchon (1999) work very well to estimate the downwelling flux of longwave radiation by comparing these to estimates from observation, satellite, and reanalysis datasets, with r<sup>2</sup> ranging from 0.87 to 0.98 across the datasets for clearsky and all sky conditions with r<sup>2</sup> ranging from 0.87 to 0.98 across the datasets for clear-sky and all-sky conditions. We then showed that one can use these equations to decompose this flux into different components, and relate changes to differences in cloud cover, water vapor, and lower-level atmospheric heat storage. We found that most diurnal changes in downwelling longwave radiation are caused by differences in lower-level atmospheric heat storage that are reflected in differences in surface air temperature, with the changes in atmospheric emissivity playing the second role. The dominance of surface air temperature can be also observed in the seasonal range in R<sub>lst</sub>, except in tropical monsoon regions due to large variations of water vapor. As for the spatial variation, from arid to humid region, the increasing lower level atmospheric heat storage and decreasing atmospheric emissivity have a offsetting effect on the Rid variation, thus leading to relatively subtle changes in RId along with aridity index.—We found that most diurnal changes in downwelling longwave radiation are caused by differences in lower-level atmospheric heat storage that are reflected in differences in surface air temperature, with the changes in atmospheric emissivity playing the secondary role. The dominance of- surface air temperature can be also observed in the seasonal ranges of  $R_{Id}$ , except in tropical monsoon regions due to large variations in  $\frac{1}{2}$  water vapor and cloud-cover. As for the spatial variation, from arid to humid region, the increasing lower-level atmospheric heat storage and decreasing atmospheric emissivity have an offsetting effect on the R<sub>Id</sub> variation, thus <u>leading to relatively subtle changes in Rld along with aridity index.</u>

Relating our decomposition to radiative kernel helps to gain a more comprehensive understanding of variations in R<sub>1d</sub>. Referring to the sensitivity in the downwelling longwave radiation for an incremental

292 change in an atmospheric property (e.g., Ta, fc, and ea), radiative kernel has been used to attribute R<sub>Id</sub> changes, based on numerically calculation with radiative transfer code (Previdi 2010 and Vargas Zeppetello 293 294 et al. 2019) or partial differentiating with explicit formula for R<sub>ld</sub> (Shakespeare and Roderick, 2022). 295 Following Shakespeare and Roderick (2022), the approximate radiative kernel of Ta, fc, and ea are calculated <u>based on Eqs. 8-9 (i.e.,  $\frac{\partial R_{ld}}{\partial T} = 4\sigma \overline{\varepsilon} \overline{T}_a^3 \underbrace{\frac{\partial R_{ld}}{\partial f_c}} = \sigma \overline{T}_a^4 \times \left(1 - 1.24 \left(\frac{\overline{e_a}}{\overline{T}_a}\right)^{\frac{1}{7}}\right)$ , and  $\frac{\partial R_{ld}}{\partial e_a} = \sigma \overline{T}_a^4 \times \frac{1.24}{7} \underbrace{\frac{(1 - \overline{f_c})^2}{(e_a - \overline{f_c})^2(T_a)}}$ </u> 296 297 and shown in the left panel of Fig. S8. As shown in Fig S8a,- the sensitivity of R1d to Ta peaks in the tropics 298 with a maximum of around 5 W/m<sup>2</sup>/K and decreases at higher latitudes, which is generally consistent with 299 Shakespeare & Roderick (2022). Moreover, the seasonal cycle of the atmospheric properties themselves 300 are shown in the right panel of Figure S8, which reveals that the spatial distribution of the contribution of 301  $T_a$ ,  $e_a$ , and  $f_c$  to the seasonal variations in  $R_{ld}$  (Figure 5) is dominated by the seasonal changes of the air 302 properties (Figs. S8b, S8d, and S8f) instead of the sensitivity of R<sub>ld</sub> to them (Figs. S8a, S8c, and S8e). 303 Relating our decomposition to radiative kernerl helps to gain a more comprehensive understanding of variations in Rie. Referring to the sensitivity in the downwelling longwave radiation for an incremental 304 305 change in an atmospheric property (e.g., Ta, fe, and ea), radiative kernel has been used to attribute R44 changes, based on numerically calculation with radiative transfer code (Previdi 2010 and Vargas Zeppetello 306 et al. 2019) or partial differentiating with explicit formula for Rtd (Shakespeare and Roderick, 2022). 307 308 and Roderick (2022), the approximate radiative kernel of T. 309 310 311 together with the seasonal range of the atmospheric property themselves. As shown in Fig S4, the radiative 312 These equations can then be applied to different aspects of climate research.- For instance, the values of downwelling longwave radiation are often missing in FLUXNET data (Table S2), and these equations can 313 314 be used to fill the gaps with air temperature and humidity observations. We can also use these equations to 315 better understand the physical mechanisms for temperature change due to extreme events. For instance, Park et al. (2015) and Alekseev et al. (2019) found that an enhancement of downwelling longwave radiation 316 317 in the Arctic is found to be preceded by the advection of moisture and heat. -The equations by Brutsaert (1975) and Crawford and Duchon (1999) can then be used to quantify the individual contributions by the 318 319 advection of heat and moisture (Tian et al. 2022).- Another example is the attribution of differences in 320 temperature<del>global warming</del> magnitudes across humid and arid regions (Ghausi et al., 2023). Du et al. 321 (2020) used these equations to explain why global warming was stronger during clear-sky conditions in 322 observations in China due to the greater sensitivity of clear-sky emissivity to a change in water vapor. This 323 was then used to explain the observed, stronger global warming in the arid regions of China, which have 324 less clouds and a higher frequency of clear-sky conditions than the humid regions. Furthermore, -w\text{\psi}hile 325 the empirical coefficient of 1.24 in Eq. (1) may change due to emissivity changes from greenhouse gases 326 other than water vapor, this formulation can nevertheless provide a useful basis in terms of the interannual 327 changes of R<sub>Id</sub>, which is shown in Fig. S9. As shown in Fig. S9a, R<sub>Id</sub> increases in most of the land regions, 328 at an average rate of 0.64 W/m<sup>2</sup>/decade, with the contribution of increased temperature, increased water 329 vapor, and decreased cloud cover contributing 0.46, 0.28, -0.10 W/m<sup>2</sup>/decade, respectively. Furthermore,

it can be observed in Figs. S9d-S9i that the temperature effect is generally around 0.5 W/m²/decade, while

the influence of emissivity is significantly dominant in the monsoon region, which is majorly due to the

It is worth noting that several effects on Rld variations are not included in B75 and C&D99, e.g., the well-

mixed greenhouse gas concentrations (Shakespeare and Roderick, 2022), large aerosol particles (Zhou and

Savijärvi. 2013), and cloud base (Viúdez-Mora et al. 2015). Although rarely influencing the diurnal change,

330

334

335

interannual changes in water vapor.-

336 seasonal cycles, and spatial distribution, these terms needs attention when the interannual trend of Rld is 337 investigated under global warming, which can be implied by the difference between Figs. S9a and S9b. In 338 addition, B75 in conjunction with C&D99 is adopted in this work to decompose the Rld variations in 339 different spatial-temporal scales, considering its solid physical foundations and the relatively less 340 computation consumption, Further analysis can be performed based on other estimations, e.g. Prata 1996, which shows consistency with reanalysis data (Allan et al. 2004). The cloud effect can be also detected 341 342 using the difference between all-sky and clear-sky Rld (Allan 201; Ghausi et al., 2022). Moreover, datasets that are more focused on radiation and energy budget can be used to test the robust of the results, e.g., 343 344 BSRN (Driemel et al. 2018) and GEBA (Wild et al. 2017).

We conclude that the equations by Brutsaert (1975) and Crawford and Duchon (1999) are still very useful to advance our understanding of surface temperature changes. We conclude that the equations by Brutsaert (1975) and Crawford and Duchon (1999) are still very useful to advance advancing our understanding of surface temperature changes. Our evaluation has shown how well these equations estimate this flux, and our application to the decomposition of different contributions has shown its utility to understanding understanding the causes for of climate variability, extreme events, and global warming, linking these to the mechanistic contributions by downwelling longwave radiation.

**Figure 1.** Spatial distribution of  $(\underline{a},\underline{c})$ -the-climatological mean-and  $(\underline{b},\underline{d})$ -the seasonal amplitude of downward longwave radiation and absorbed solar radiation at the surface respectively from the NASA-CERES dataset. The seasonal amplitude is calculated as the difference between the maximum and minimum monthly data.

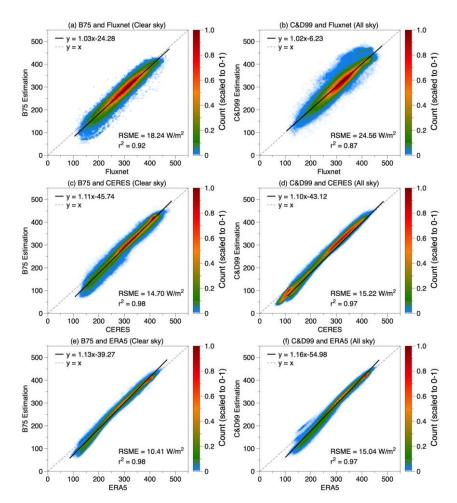

Figure 2, Comparison of RId estimated by Brutsaert (1975) (a, c, e) for clear-sky conditions and by Crawford and Duchon (1999) (b, d, f) for all-sky conditions using (a, b) FLUXNET hourly data of 189 sites, (c, d) NASA-CERES monthly data of 1°×1° from 2001 to 2018 and (e, f) ERA5 monthly data of resolution of 1°×1° from 1979 to 2021. Colors indicate the density of the data points and is scaled to values between 0 - 1.

 Comparison of  $R_{ld}$  estimated (a, c, e) by Brutsaert (1975) for clear sky conditions and (b, d, f) by Crawford and Duchon (1999) for all sky conditions using FLUXNET hourly data of 189 sites (a, b), NASA CERES

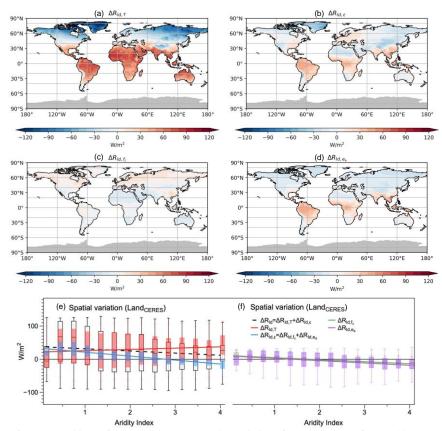

**Figure 4.** The multi-year average diurnal variations in  $R_{ld}$  (black dashed line) and its decomposition into contributions by changes in emissivity (blue,  $\Delta R_{ld,\varepsilon}$ ) and lower-level atmospheric heat storage (red,  $\Delta R_{ld,T}$ ) in the FLUXNET dataset aggregated over 189 sites for (a) (a) the whole year, (b) -(b)-June-August, -and (c) (e)-December - February, -The box shows the variation among the 189 sites. The upper and lower whiskers indicate 95<sup>th</sup> and 5<sup>th</sup> percentiles, upper boundary, median line, and lower boundary of the box indicate the 75<sup>th</sup>, 50<sup>th</sup>, and 25<sup>th</sup> quantiles, respectively. For each site and each day, the daily mean value is removed, with the deviations shown. Regression lines are based on site-mean or grid-mean value using LOESS regression.

**Figure 5.** Decompositions of the mean seasonal variation ( $\Delta$ , difference between the maximum and minimum monthly data at each grid) of  $R_{ld}$  in the NASA-CERES dataset into contributions by (a) lower-level atmospheric heat storage ( $\Delta R_{ld,T}$ ) (a) and (b) emissivity ( $\Delta R_{ld,\varepsilon}$ ), (b), a and (c) their latitudinal

variations  $\underline{(e)}$ . Decomposed of  $\Delta R_{ld,\varepsilon}$  into contributions by variations in  $\underline{(d)}$  cloud cover  $(\Delta R_{ld,f_c})$   $\underline{(d)}$  and  $\underline{(e)}$  humidity  $(\Delta R_{ld,e_a})$ ,  $\underline{(f)}$ , their latitudinal variations,  $\underline{(f)}$ . In Figs. a, b, d, e, grey shading indicates missing values. In Figs. c and f, the box shows the variation among the land grids at the same latitude, while the solid line is their mean. The upper and lower whisker indicate 95<sup>th</sup> and 5<sup>th</sup> percentiles, upper boundary, median line, and lower boundary of the box indicate the 75<sup>th</sup>, 50<sup>th</sup>, 25<sup>th</sup> quantiles, respectively.

**Figure 6.** Decompositions of the multiyear-mean spatial variation of  $R_{ld}$  (deviations of the multiyear-mean value for each grid from the land-mean value) in the NASA-CERES dataset into contributions by (a) lower-level atmospheric heat storage ( $\Delta R_{ld,T}$ ) (a) and (b) emissivity ( $\Delta R_{ld,\varepsilon}$ ). (b) Decomposition of  $\Delta R_{ld,\varepsilon}$  into contributions by (c) variations in cloud cover ( $\Delta R_{ld,f_c}$ ) (e) and (d) d-humidity ( $\Delta R_{ld,e_a}$ ) (d). Ins Figs. a-d, grey shading indicates missing values. In Figs. e and f, the box shows the variation among the land grids with the same aridity. The upper and lower whisker indicate 95th and 5th percentiles, upper boundary, median line, and lower boundary of the box indicate the 75th, 50th, 25th quantiles, respectively.

#### Plain Language:

Downward longwave radiation ( $R_{td}$ ) plays an important role in surface energy balance and is critical for global warming. However, its spatiotemporal climatological variation on a global scale has not been explained well with a solid physical basis. To fill this gap, we here use a semi empirical equation derived by Brutsaert (1975, "B75") and its extension by Crawford and Duehon (1999, "C&D99") to identify the leading terms responsible for the diurnal range, seasonal cycle, and geographical variations in  $R_{td}$ . We show that B75 and C&D99 work very well when evaluated against global observations from satellites and FLUXNET sites. We then used these physics based equations to show that diurnal and seasonal variations in  $R_{td}$  are predominantly controlled by changes in atmospheric heat storage. When moving from humid to arid regions, while the contribution of atmospheric heat storage increases, the ones from clouds decreases, which together explains the relatively small decrease in  $R_{td}$  with aridity. Our work provides a clue to better understand aspects of climate variability, extreme events, and global warming, by linking these to the mechanistic contributions by downwelling longwave radiation.
