19
20 **Abstract** Beginning in December 2020, a series of small-to-medium, torrent-like pulses commenced
21 upon a historic debris cone located within the Nupchu valley, Kanchenjunga Conservation Area (KCA),
22 Nepal. Sometime between 16 and 21 August 2022 a comparatively large ice-debris avalanche event
23 occurred, covering an area of 0.6 km² with a total estimated volume of order 10⁶ m³. The area of the
24 debris cone left by the August 2022 event increased the historic debris cone area by 0.2 km² (total
25 area: 0.6 km²). Although no human or livestock deaths occurred, the increase in torrent-like pulses of
26 debris upon this historic debris cone since 2020 exemplifies a style of mass movement that may
27 become increasingly common as air temperatures to rise in the region. Although the magnitude of
28 this event was small compared to events like the 2021 Chamoli avalanche, the widespread distribution
29 and frequency of comparable events presents a substantial, and potentially increasing, hazard across
30 High Mountain Asia.

31
32 **1 Introduction**

33
34 Large magnitude but low frequency events in the high mountains can include a variety of familiar and
35 poorly understood cryospheric processes, including glacial lake outburst floods (GLOFs) (Lamsal et al.,
36 2014), snow/ice/rock avalanches (Shugar et al., 2021), landslide-induced avalanches and floods (Byers
37 et al., 2019), englacial conduit floods (Rounce et al., 2017), and others (see: Byers et al. 2022). Today,
38 enhanced communications and remote sensing technologies enable rapid identification and location
39 of such events, often within hours of their occurrence. Many, however, remain unreported because of
40 their remoteness, inaccessibility, poor communications, and/or absence of people (see: Byers et al.,
41 2020). In this *Brief Communication*, we report on a large ice-debris avalanche that occurred sometime
42 between 16 and 21 August 2022 in the Kanchenjunga Conservation Area (KCA), eastern Nepal. The
43 event is noteworthy not only because of its probable linkages to climate change impacts in the region,
44 but also because local residents were unaware of its occurrence, as were the Government of Nepal
45 and climate change research entities in Kathmandu. Here we briefly document the event and describe
46 its present and future implications for local communities, scientists, and governments.

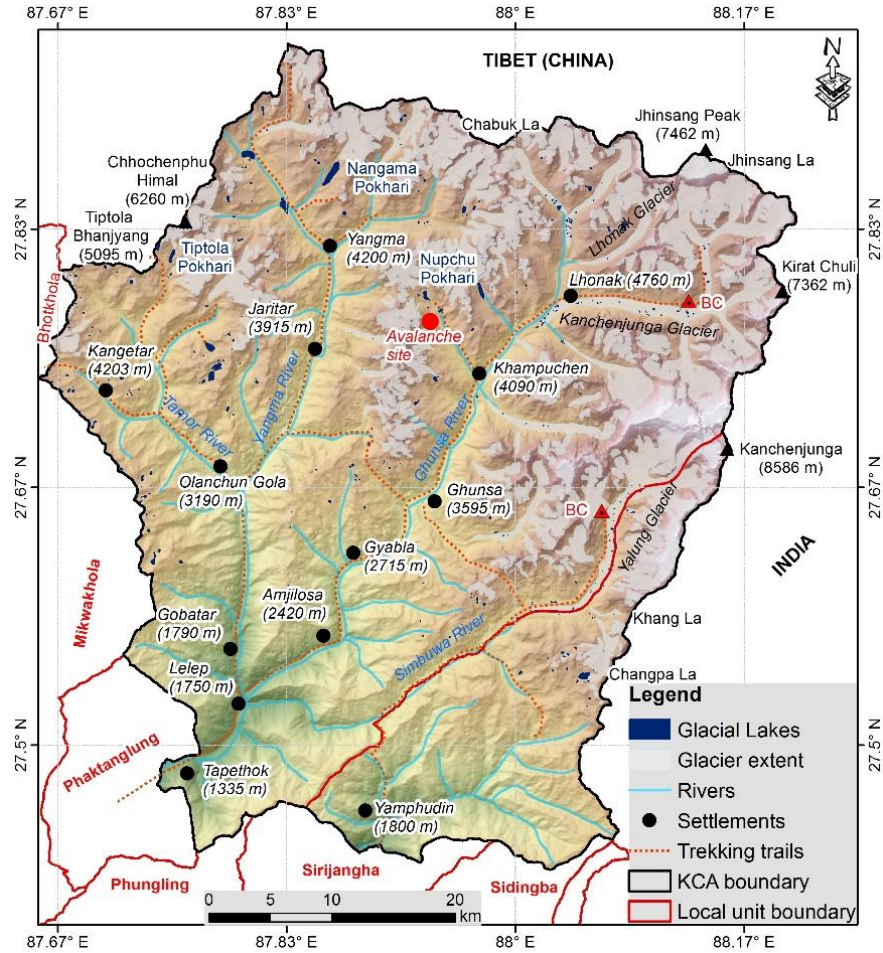

Figure 1. Kanchenjunga Conservation Area and location of the Nupchu ice-debris avalanche.

2 Setting

The KCA is a 2,035 km² protected area established in 1997 by the Nepalese Department of National Parks and Wildlife Conservation, with management responsibility handed over to local communities in 2006 (WWF Nepal 2018) (Figure 1). It is home to a range of ethnic groups of primarily Tibeto-Burman origin that include Limbu, Rai, Tamang, Gurung, Magar, Chhetri, and Sherpa (Thapa, 2009). Livelihoods were traditionally based upon agriculture, livestock raising, and trade with Tibet, but globalization, outmigration, and new road construction over the past 15 years has rapidly changed the character of both the social and environmental landscape. The South Asian monsoon dominates weather patterns, with most rainfall falling between June and September (Kandel et al., 2019).

Based upon an analysis of 1962–2000 satellite imagery, valley and mountain glaciers in the KCA cover approximately 488 ± 29 km² and exhibit an overall negative glacier surface area loss of 0.5 ± 0.2% yr⁻¹ (Racoviteanu et al., 2015). Valley glaciers are largely debris-covered and have been receding since the most recent maximum during the Little Ice Age. Hooker (1854), for example, wrote in 1849 of observing glacial moraines that provided proof “...of glaciers having once descended to from 8,000 to 10,000 feet in every Sikkim and east Nepal valley...” (Hooker, 1854: 166). The British alpinist Freshfield (1903: 236) writes of the “glacial shrinkage” he encountered in the Lhonak region in 1899, as well as

69 throughout both the Nepal and Sikkim sides of the Kanchenjunga massif. Although the Kanchenjunga
70 region received some of the earliest study, exploration, and mountaineering expeditions in Nepal by
71 outsiders (Thapa 2009), relatively little glacier and cryospheric hazards research has been conducted
72 to date. For example, until 2019 only one GLOF event was on record for the region (Watanabe et al.,
73 1998; ICIMOD, 2011), although subsequent research revealed that at least seven others had occurred
74 since 1921 (Byers et al., 2020). The Nupchu valley, where the ice-debris avalanche of concern
75 occurred, is used seasonally for yak herding, potato farming, and tourism, with four operational tourist
76 lodges in the village of Kampuchen as of the fall of 2022 (Figure 1).

77 **3 Methods**

78
79 Field-based observations and assessments of Nupchu Pokhari (glacial lake), other nearby lakes, and
80 the ice-debris avalanche were conducted between 1–20 September 2022. Methods included GPS-
81 based route mapping, photography of avalanche features, oral testimony, and literature reviews. A
82 Nikon Forestry Pro Rangefinder was used to measure the depth of ice/debris deposits where the
83 Nupchu river had incised deposits down to the original streambed. Historic (declassified KH-9 Hexagon
84 satellite imagery; see: Maurer et al., 2019; Dehecq et al., 2020) and recent (Planet Dove and
85 SuperDove) satellite imagery revealed the sequence of avalanche/debris flow events between 1975
86 and 2023 (Figure 2). Numerical simulations of the avalanche were conducted using R.Avaflow version
87 3 (Mergili and Pudasaini, 2014–2023; Mergili et al., 2017), a state of the art software that has been
88 used globally to study ice/rock avalanches events (Zhang 2022). Numerical simulations were used to
89 provide upper limit volume estimation of the avalanche, which were constrained by field observations.
90 We used the parameters from Zhang et al. (2022) to produce a single-phase model scenario for three
91 different volumes: 1, 2.5, and 5 million m³. For calibration, we modified the internal friction angle of
92 the mixture to match the extension of the debris left by event. For the terrain elevation, an ALOS
93 PALSAR Radiometric Terrain Corrected high-resolution 12.5 m DEM was used
94 (AP_13152_FBD_F0540_RT1) (ASF DAAC, 2014).

95 **4 The Event**

96 The investigation of the Nupchu valley was initiated by local concerns about Nupchu Pokhari
97 (27.790708° N, 87.934275° E) as being one of the most dangerous glacial lakes in terms of a potential
98 GLOF (Figure 1). Periodic, smaller floods from the upper Nupchu valley were reported, and assumed
99 locally to have originated in the Nupchu Pokhari, although no supporting evidence was available. Our
100 field reconnaissance results of Nupchu Pokhari on 12 September 2022, however, suggested that the
101 lake posed a moderate risk of flooding, largely based on the absence of overhanging ice and other
102 potential flood triggers. This assessment corroborates the findings of Rounce et al. (2017) which
103 concluded that the 0.129 km² Nupchu Pokhari presented only a moderate risk of flooding because of
104 (a) no apparent growth between 2000 and 2015, (b) absence of avalanche pathways into the lake (i.e.,
105 in line with the direction of the lake and its outflow), and (c) absence of landslide pathways entering
106 the lake.

107 The August 2022 ice/debris avalanche event was unexpected. Field staff had conducted a
108 reconnaissance of the valley below Nupchu Pokhari in early August 2022 to check out potential
109 camping sites, at which time the upper valley was primarily pastureland. When the field team and A.C.
110 Byers returned in early September, the original path was blocked by massive ice-debris avalanche
111 material (27.774328° N, 87.941064° E) that had clearly occurred at some point in the interim (Figure

112 2). Our team and *dzopkio* (yak-cattle crossbreeds used as pack animals) were nevertheless able to
113 climb up and over the avalanche debris to the upper Nupchu valley, but at the time the source and
114 triggers related to the event remained unknown.

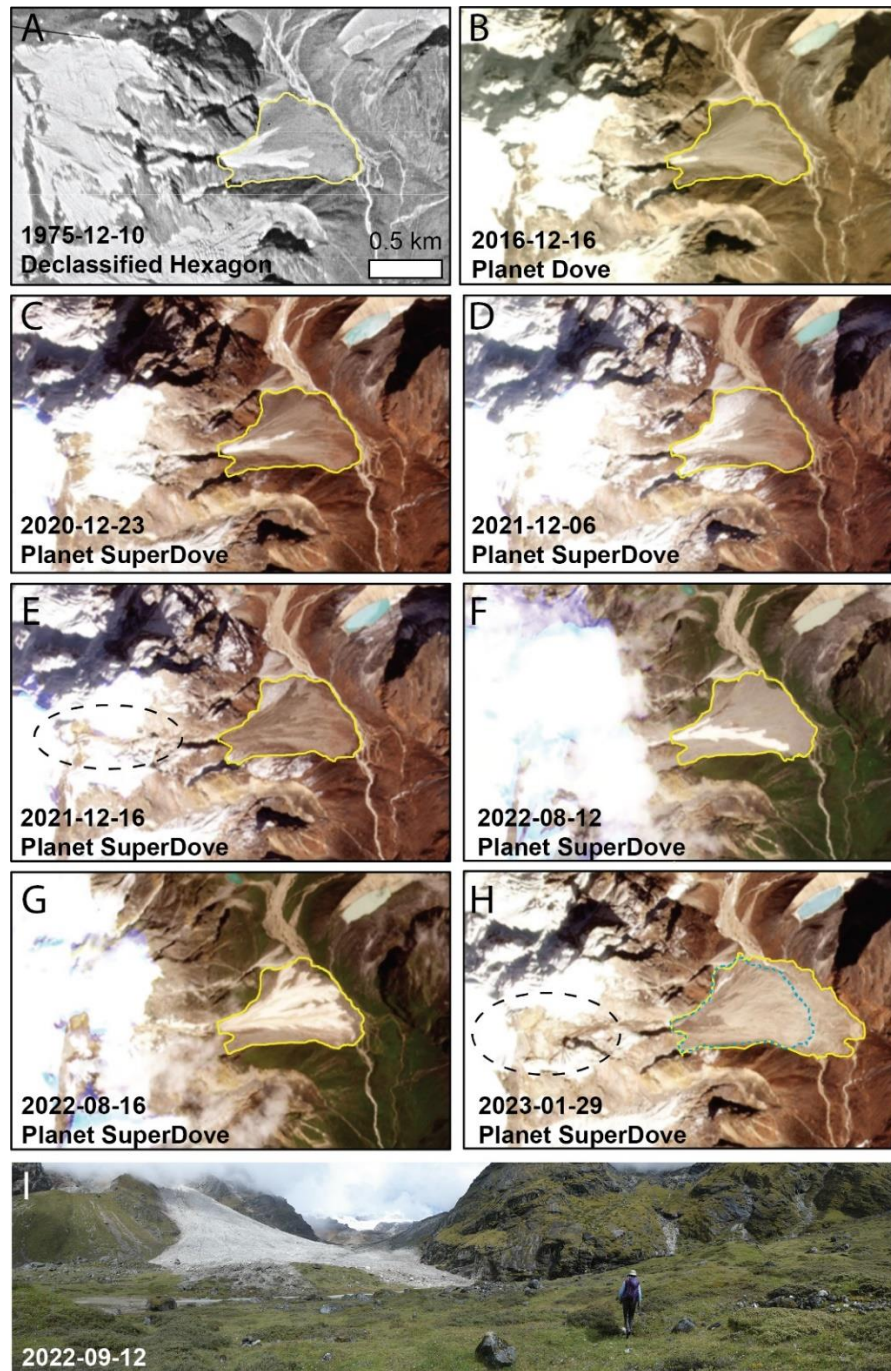

115 The original historic debris cone was found to have covered an area 0.402 km² that had been relatively
116 stable for at least 45 years, based upon the oldest satellite imagery available (i.e., 1975) (Dehecq et al.,
117 2020) (Panel A, Figure 2). Time series satellite images revealed the periodic occurrence of surficial
118 debris flows upon this original deposition. That is, beginning in 2020, a series of small-to-medium,
119 torrent-like pulses commenced (Panel C through G, Figure 2), culminating in the relatively large event
120 that occurred sometime between 16 and 21 August 2022 (Panel H, Figure 2). The area of the debris
121 cone left by the August 2022 event increased the original area covered by 0.2 km² (total area: 0.6
122 km²). Of the three different volume estimates tested (1, 2.5, and 5 million m³) using R.Avaflow, an
123 avalanche volume of 1 x 10⁶ m³ most consistently matched the extent (red line) and depth of the new
124 debris cone deposited as determined by our field observations (Figure 3).

125
126 Our team was unable to locate the event on any seismographs, most likely related to the absence of
127 instrumentation in this part of the eastern Himalayas. Based upon direct field observations as well as
128 satellite imagery, the avalanche had clearly blocked and temporarily dammed the water from the
129 Nupchu Khola (river) at its onset, which was nevertheless able to cut down through the ice and
130 sediment deposited to form a steep canyon estimated at >10 m depth. The presence of shrubs (e.g., *J.*
131 *indica*) fully stripped of their bark was testimony to the high velocities of the flood- and meltwater
132 produced by frictional forces during the event, a phenomenon reported for other rockfall-induced
133 landslides in Nepal (Byers et al., 2019).

134 135 **5 Discussion**

136
137 Interestingly, individuals in the community of Kampuchen, only 5 km downstream of the event, were
138 unaware of the avalanche. Yak herds had already returned from the high pastures to the village by
139 early August, the community was busy harvesting potatoes and preparing for the fall tourist season,
140 and no obvious changes in the Nupchu Khola had been observed (e.g., Kargel, 2014 for a description of
141 changes in the Seti Kosi prior to the catastrophic flooding of 5 May 2012). Thus, authorities in
142 Taplejung and Kathmandu were also unaware of the event as of September 2022, which is typical of
143 many large-scale cryospheric events in remote regions of the Himalayas (e.g., Byers et al., 2022).

144
145 Still, the acceleration of torrent-like pulses of debris upon the historic debris cone since 2020 suggests
146 that these events may be linked to contemporary warming trends, similar to those that may have
147 triggered larger-scale mass wasting events elsewhere in the Himalaya (e.g., Shugar et al.,
148 2021; Kääh et al., 2021; Taylor et al., 2023). The frequency of such ice-debris flow events within the
149 KCA region, and more broadly across the Himalaya, is unknown. However, with projections of
150 continued warming in these regions (e.g., Lalande et al. 2021), a more systematic approach to
151 determining their historic frequency, as well as a better understanding of their triggers, is warranted.
152 After further evaluation, vulnerable villages, such as Kampuchen, may wish to consider the installation
153 of preventative floodwater diversion mechanisms, such as the rock-filled gabion walls currently
154 protecting tourist lodges in the Mt. Everest region (e.g., Rounce et al., 2017; Byers et al., 2022) using
155 participatory processes as outlined in Watanabe et al. (2016).

 157
 158
 159
 160
 161
 162
 163
 164

Figure 2. A time series of satellite images showing the periodic occurrence of surficial debris flows upon the original deposition. These appear to have accelerated in both frequency in magnitude beginning several years ago, leading up to the main event that occurred between 16 and 21 August 2022. Blue dashed outline in panel H is the 1975 outline of the debris cone, while the dashed black circle identifies the failure zone. The photograph at the bottom provides an oblique view of the ice/debris avalanche about three weeks after it occurred (photograph by A. Byers). Panel H shows an image from early 2023, as imagery from immediately after the ice-avalanche in mid-August 2022 were partially obscured by clouds (KH-9 imagery courtesy of USGS; Planet Dove and SuperDove imagery courtesy of Planet Lab PBC).

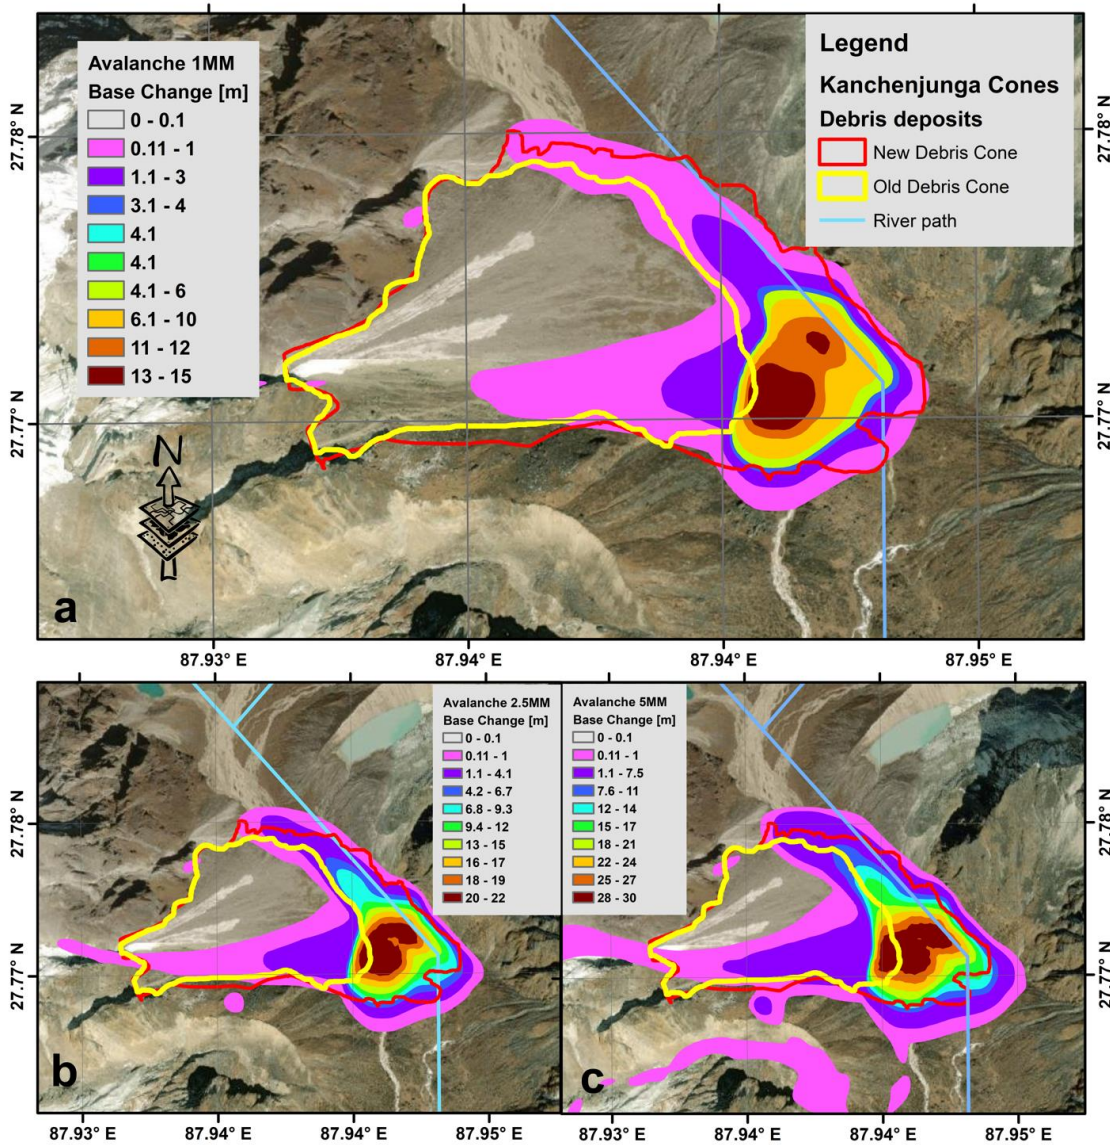

Figure 3. Surface elevation change modeled with R.Avaflow for three different avalanche volumes: $1 \times 10^6 \text{ m}^3$ (top), $2.5 \times 10^6 \text{ m}^3$ (bottom left) and $5 \times 10^6 \text{ m}^3$ (bottom right). Of the three estimates, $1 \times 10^6 \text{ m}^3$ most consistently matched the extent and depth of the new debris cone deposited in August 2022 (red line; the yellow line represents the extent of the historic debris cone).

5 Conclusion

Beginning in 2020, a series of small-to-medium, torrent-like pulses commenced upon a historic debris cone located approximately 2 km down valley from the lake, culminating in a relatively large avalanche event that occurred sometime between 16 and 21 August 2022. The August 2022 event deposited debris with an area of 0.6 km^2 and estimated volume in the order of 10^6 m^3 . No fatalities from the event occurred because of the absence of humans and livestock in the vicinity when the event occurred. Likewise, no impoundment of the Nupchu Khola, and formation of a potentially dangerous backwater lake, occurred as a result of debris blockage, although such scenarios happen routinely in high mountain environments.

182
183 The improvement of remote area event reporting mechanisms, especially to authorities in the capital,
184 Kathmandu, could help with the development of hazard mitigation technologies and response.
185 Likewise, more systematic monitoring of cryospheric events by scientists, using remote sensing
186 platforms and hazard mapping tools, could help with the development of more effective early warning
187 systems for vulnerable communities, livestock, and adventure tourists. Ultimately, this could lead to a
188 minimization of losses and damage due to multi-hazard events.
189

190 *Data availability.* Declassified KH-9 Hexagon satellite imagery is available at
191 <https://earthexplorer.usgs.gov/>. Planet Dove and SuperDove satellite imagery is available
192 at <https://www.planet.com/explorer/>. The ALOS PALSAR Radiometric Terrain Corrected high-res
193 DEM"AP_13152_FBD_F0540_RT1" used for the R.Avaflow is available at
194 <https://search.asf.alaska.edu/>.

195
196 *Author contributions.* ACB conceived the study and wrote the original narrative, with contributions
197 from MS-V, DS, DM, MBC, and RA. MBC created Figure 1, DS and RA created Figure 2, and MS-V
198 created Figure 3. MS-V conducted the numerical simulations of avalanche volumes shown in Figure 3.
199 All authors revised and contributed to the final manuscript.
