17 This study explores coupled land-atmosphere data assimilation (DA) for improving
18 weather and hydrological forecasts by assimilating soil moisture (SM) data. This study
19 integrates a land DA component into a global atmospheric DA system of the Nonhydrostatic
20 ICosahedral Atmospheric Model and the Local Ensemble Transform Kalman Filter and
21 performs both strongly and weakly coupled land-atmosphere DA experiments. We explore
22 various types of coupled DA experiments by assimilating atmospheric observations and SM
23 data simultaneously. The results show that analyzing atmospheric variables by assimilating SM
24 data improves the SM analysis and forecasts and mitigates a warm bias in the lower troposphere
25 where a dry SM bias exists. On the other hand, updating SM by assimilating atmospheric
26 observations has detrimental impacts due to spurious error correlations between the
27 atmospheric observations and land model variables. We also find that assimilating SM by
28 strongly coupled DA is beneficial in the Sahel and equatorial Africa from May to October.
29 These regions are characterized by seasonal variations in the precipitation patterns and benefit
30 from updates in the atmospheric variables through SM DA during periods of increased
31 precipitation. Additionally, these regions coincide with those identified in the previous studies,
32 where a global initialization of SM would enhance the prediction skill of seasonal precipitation.

33 **1. Introduction**

34 The Earth's natural environment can be considered a unified system in which several
35 subsystems (e.g., atmosphere, hydrosphere, cryosphere, and biosphere) interact with each
36 other. Coupled models consider at least two of the Earth's subsystems and have been developed
37 to emulate such interactions within unified systems. For example, coupled land-atmosphere
38 models consider land-atmosphere interactions by passing the output data from the land
39 subsystem to the atmospheric subsystem and vice versa during model time integrations.
40 Coupled models represent more realistic physical processes and provide improved predictions
41 of Earth's phenomena compared to those models that consist of only a single component.

42 Data assimilation (DA) plays an important role in numerical weather prediction (NWP) by
43 providing accurate initial conditions. Some studies investigated coupled DA for ocean-
44 atmosphere interactions (e.g., Zhang et al., 2007; Sugiura et al., 2008; Fujii et al., 2009; Frolov
45 et al., 2016; Laloyaux et al., 2016; Sluka et al., 2016; Browne et al., 2019; Penny and Hamill
46 2017; Penny et al., 2019) and land-atmosphere interactions (e.g., de Rosnay et al., 2012; Lea

47 et al., 2015; Suzuki et al., 2017; Sawada et al., 2018; Draper and Reichle, 2019; Fairbairn et
48 al., 2019).

49 In this study, we focus on experiments to evaluate the potential benefits of assimilating
50 synthetic soil moisture (SM) data from the Global Land Data Assimilation System (GLDAS;
51 Rodell et al., 2004), within a controlled experimental setup through the effective use of land-
52 atmosphere interactions via data assimilation. Specifically, this study investigates whether
53 assimilating atmospheric (land) observational data into land (atmospheric) models is beneficial
54 for their subsequent forecasts. We employ SM data from GLDAS, a comprehensive and
55 reliable dataset which facilitates simple data handling and is suitable and sufficient for this
56 study (cf. Section 2d). SM is particularly important among land variables because it controls
57 the exchange of water and energy between the atmosphere and land surface (Bateni and
58 Entekhabi, 2012). For example, SM has a profound impact on the evolution of boundary layers
59 and precipitation during the warm season, a time characterized by high incoming radiation and
60 evapotranspiration (Betts, 2009; Dirmeyer and Halder, 2016; Drusch and Viterbo, 2007).
61 Moreover, improving SM data is essential for enhancing seasonal-scale climate predictions
62 (Dirmeyer, 2000; Douville and Chauvin, 2000; Drusch, 2007; Hauser et al., 2017). With a
63 regional NWP system, Santanello et al. (2019) showed that SM DA changed surface fluxes,
64 evolution, and entrainment of the planetary boundary layer, and ambient weather.

65 Two well-known coupled DA methods are weakly coupled DA and strongly coupled DA
66 (cf. section 2.b). As one argument, Lawless (2012) noted that strongly coupled DA is preferable
67 for environmental prediction, as discussed at the 2012 International Workshop on Coupled
68 Data Assimilation. A follow-up workshop in Toulouse in 2016 further elaborated on the need
69 for coupled DA. As for ocean-atmosphere models, Penny et al. (2019) explored a method to
70 improve the initialization process using a simplified model. They estimated ocean conditions
71 with atmospheric observations and vice versa, and found strongly coupled DA approaches were
72 generally superior to weakly coupled approaches when using the simple toy model. As Tang
73 et al. (2021) stated, however, regarding more complex models, it is unclear whether strongly
74 coupled DA generally outperforms weakly coupled DA. When it comes to land-atmosphere
75 models, several studies have demonstrated the benefits of strongly coupled DA approaches for
76 medium-range NWP (Suzuki et al., 2017; Sawada et al., 2018). In terms of assimilation of land
77 observations, while weakly coupled land-atmosphere DA is still the mainstream in NWP
78 systems (e.g., Zhang et al., 2007; Lea et al., 2015; Draper and Reichle, 2019), several studies

79 have already examined the benefits of strongly coupled DA on land observations. For example,
80 Lin and Pu (2019, 2020) assimilated surface SM, 2-m temperature and humidity, and
81 conventional atmospheric observations, showing advantages of strongly coupled DA. They
82 also showed that SM had crucial impacts on the temperature field rather than the other
83 variables. Thus, it is already known that SM DA is beneficial for the coupled land-atmosphere
84 models, but updates of cross-components have not yet been explored enough. Therefore, this
85 study aims at exploring better strategies to assimilate SM data in a strongly coupled land-
86 atmosphere DA system.

87 This study uses a global atmospheric DA system known as the NICAM-LETKF (Terasaki
88 et al., 2015), which consists of the Nonhydrostatic Icosahedral Atmospheric Model (NICAM;
89 Satoh et al., 2008, 2014) and the Local Ensemble Transform Kalman Filter (LETKF; Hunt et
90 al., 2007). NICAM incorporates the Minimal Advanced Treatments of Surface Interaction and
91 RunOff model (MATSIRO; Takata et al., 2003) as the land surface subsystem. We implement
92 coupled land-atmosphere DA in NICAM-LETKF to assimilate SM observations using either
93 the weakly or strongly coupled DA methods. Our primary scientific question is whether the
94 assimilation of synthetic observational data from one model into another can improve
95 compatibility between the two models in the NICAM-LETKF system. In addition to
96 conventional atmospheric observations and AMSU-A radiances in NICAM-LETKF, this study
97 assimilates SM data as land observations.

98 This article is organized as follows. Section 2 describes the newly developed coupled land-
99 atmosphere DA system. The experimental settings are described in Sec. 3. The results are
100 presented and discussed in Sec. 4. Finally, a summary is provided in Sec. 5.

101 **2. Methodology**

102 *a. NICAM and MATSIRO models*

103 NICAM is an icosahedral-grid-based atmospheric model that has been widely used for
104 NWP (e.g., Kotsuki et al., 2019b, 2019c) and climate-scale predictions (e.g., Kodama et al.,
105 2015; Kikuchi et al., 2017). We use NICAM with a 112-km horizontal resolution and 38
106 vertical layers to a height of approximately 40 km. Due to the relatively coarse horizontal
107 resolution, the Arakawa and Schubert scheme (Arakawa and Schubert, 1974) and Berry's
108 parameterization (Berry, 1967) are employed for cumulus parameterization and the large-scale

109 condensation scheme, respectively. See Satoh et al. (2008) and Satoh et al. (2014) for further
 110 details about NICAM.

111 MATSIRO represents all the major processes of water and energy exchange between land
 112 and atmosphere. MATSIRO consists of five vertical layers used for simulating soil temperature
 113 and moisture: 0–0.05, 0.05–0.25, 0.25–0.5, 0.5–0.75, and 0.75–2 meters. Surface energy and
 114 water fluxes are computed from their budgets at the ground and canopy surfaces in snow-free
 115 and snow-covered regions, considering the subgrid-scale snow distribution (Takata et al.,
 116 2003). SM is calculated in each soil layer and is representative of the entire land component of
 117 a model grid area, whether snow-covered or not. Note that, in general, SM in NWP models has
 118 been updated using 2-m temperature and humidity observations for decades (e.g. Mahfouf et
 119 al., 2000; de Rosnay et al., 2014; Gomez et al., 2020).

120 *b. LETKF and coupled data assimilation implementations*

121 LETKF is a type of ensemble Kalman filter (EnKF; Evensen, 2003) that has been used
 122 for atmospheric, hydrological, and oceanic DA. LETKF solves the analysis equations at every
 123 model grid point by assimilating the subset of observations within its localization influence
 124 radius. The analysis equations of LETKF are based on the ensemble transform Kalman filter
 125 (Bishop et al., 2001):

$$126 \quad \bar{\mathbf{x}}^a = \bar{\mathbf{x}}^f + \delta\mathbf{X}^f \bar{\mathbf{w}}^a, \quad (1)$$

$$127 \quad \bar{\mathbf{w}}^a = \tilde{\mathbf{P}}^a (\mathbf{H}\delta\mathbf{X}^f)^T \mathbf{R}^{-1} (\mathbf{y}^o - \mathbf{H}\bar{\mathbf{x}}^f), \quad (2)$$

$$128 \quad \delta\mathbf{X}^a = \delta\mathbf{X}^f \mathbf{W}^a, \quad (3)$$

$$129 \quad \mathbf{W}^a = [(m-1)\tilde{\mathbf{P}}^a]^{\frac{1}{2}}, \quad (4)$$

130 where $\bar{\mathbf{x}}$ is the ensemble-mean model state, $\delta\mathbf{X}$ is the ensemble perturbation matrix, \mathbf{H} is the
 131 linear observation operator, \mathbf{R} is the observation error covariance matrix, \mathbf{y} is the observation
 132 data, and $\tilde{\mathbf{P}}^a$ is the model state error covariance matrix in ensemble space, while superscript
 133 letters a , f , and o denote analysis (posterior), forecast (prior), and observation, respectively.
 134 Here, \mathbf{P} is used for the error covariance in model space, and $\tilde{\mathbf{P}}$ is used for the error covariance
 135 in the ensemble space. m is the ensemble size. $\bar{\mathbf{w}}$ is the $(m \times 1)$ ensemble transform vector for
 136 the ensemble mean updates, and \mathbf{W} is the $(m \times m)$ ensemble transform matrix for ensemble
 137 perturbation updates. The analysis error covariance matrix $\tilde{\mathbf{P}}^a$ is given by

$$138 \quad \tilde{\mathbf{P}}^a = [(m-1)\mathbf{I} + (\mathbf{H}\delta\mathbf{X}^f)^T \mathbf{R}^{-1} \mathbf{H}\delta\mathbf{X}^f]^{-1}, \quad (5)$$

139 where \mathbf{I} is the identity matrix. In practice, since the error covariance matrix $\tilde{\mathbf{P}}^a$ is often
 140 underestimated, and filters eventually become unstable, the introduction of the model error or
 141 variance inflation is necessary for stable filtering. The theoretical explanation of the model
 142 error can partially be attributed to the model nonlinearity under the perfect model assumption.
 143 In this study, instead of adding random noise as the model error, we use a relaxation method at
 144 the end of the DA process, as described in section 3.

145 The analysis equation of the ensemble mean (Eqs. 1 and 2) is equivalent to the original
 146 analysis equation of the Kalman filter:

$$\begin{aligned}
 147 \quad \bar{\mathbf{x}}^a &= \bar{\mathbf{x}}^f + \delta\mathbf{X}^f \tilde{\mathbf{P}}^a (\mathbf{H} \delta\mathbf{X}^f)^T \mathbf{R}^{-1} (\mathbf{y}^o - \mathbf{H} \bar{\mathbf{x}}^f) \\
 148 \quad &= \bar{\mathbf{x}}^f + \mathbf{P}^f \mathbf{H}^T (\mathbf{H} \mathbf{P}^f \mathbf{H}^T + \mathbf{R})^{-1} (\mathbf{y}^o - \mathbf{H} \bar{\mathbf{x}}^f). \tag{6}
 \end{aligned}$$

149 Here, \mathbf{P}^f is the model state error covariance matrix in model space. The EnKF uses an
 150 ensemble-based approximation to the forecast error covariance:

$$151 \quad \mathbf{P}^f \approx \frac{1}{m-1} \delta\mathbf{X}^f (\delta\mathbf{X}^f)^T. \tag{7}$$

152 For coupled models, Eq. (7) is approximated by

$$153 \quad (\mathbf{P}^f)_{\alpha\beta} \approx \frac{1}{m-1} \delta\mathbf{X}_\alpha^f (\delta\mathbf{X}_\beta^f)^T, \tag{8}$$

154 where α and β are the model variables updated in the coupled DA. Thus, for coupled land–
 155 atmosphere models, \mathbf{P}^f is represented by:

$$156 \quad \mathbf{P}^f = \begin{pmatrix} (\mathbf{P}^f)_{AA} & (\mathbf{P}^f)_{AL} \\ (\mathbf{P}^f)_{LA} & (\mathbf{P}^f)_{LL} \end{pmatrix}. \tag{9}$$

157 In Eq. (9), 'A' and 'L' represent the variables of the atmosphere and land, respectively. In the
 158 current study, for example, $(\mathbf{P}^f)_{AA}$ represents the covariance between atmospheric variables,
 159 and $(\mathbf{P}^f)_{AL}$ represents that between atmospheric variables and SM. This study employs the
 160 ensemble-based estimation of cross-component error covariance ($(\mathbf{P}^f)_{AL}$ and $(\mathbf{P}^f)_{LA}$) using
 161 Eq. (8). Here each ensemble member represents a coupled forecast where the atmospheric and
 162 land variables interact each other. Specifically, the MATSHIRO variables are driven by forcing
 163 from NICAM, and the upward flux from MATSHIRO feeds back into NICAM. This coupling
 164 captures the essential interactions between the atmosphere and land variable, leading to
 165 physically derived cross-component error covariance during the forecasts. Note that the state
 166 variable \mathbf{x}^f does not include the land component when the land variables are not updated (cf.

167 Figs. 2 a and d). For such cases, the forecast error covariance matrix also has the inverse matrix
 168 since the land component is also excluded in the background error covariance.

169 In practice, since some observations have nonlinear observation operators, the following
 170 approximation is required:

$$171 \quad \mathbf{H}\delta\mathbf{X}^f \approx H\left(\bar{\mathbf{x}}^f \mathbf{1}^T + \delta\mathbf{X}^f\right) - \overline{H\left(\bar{\mathbf{x}}^f \mathbf{1}^T + \delta\mathbf{X}^f\right)} \mathbf{1}^T, \quad (10)$$

172 where H is the nonlinear observation operator, and $\mathbf{1}$ denotes a column vector with all m
 173 elements being equal to 1.

174 For the weakly coupled DA (hereafter, WCDA) method, atmospheric observations are
 175 used only for updating NICAM state variables, and land observations are used for those of
 176 MATSIRO (Fig. 1a). That is, the cross-component error covariance between atmospheric and
 177 land variables is assumed to be 0 in WCDA (i.e., $(\mathbf{P}^f)_{AL} = 0$ and $(\mathbf{P}^f)_{LA} = 0$). Thus, impacts
 178 of atmospheric observations can propagate to land model states, and vice versa, only through
 179 interactions between NICAM and MATSIRO during model forecasts. For the strongly coupled
 180 DA (hereafter, SCDA) method, the cross-component covariance is estimated based on
 181 ensemble forecasts (i.e., $(\mathbf{P}^f)_{AL} \neq 0$, $(\mathbf{P}^f)_{LA} \neq 0$, or both are nonzero matrices). Therefore,
 182 atmospheric or land observations are used to update both NICAM and MATSIRO variables
 183 based on the cross-component covariance (Fig. 1b). SCDA extracts more information than
 184 WCDA from the same observations if an appropriate forecast error covariance $(\mathbf{P}^f)_{\alpha\beta}$ is
 185 applied.

186
 187
 188 **Figure 1.** Schematic images of (a) weakly coupled and (b) strongly coupled land–
 189 atmosphere data assimilation (DA) methods. Thin black arrows indicate model state updates
 190 through DA. Cyan double-headed arrows indicate land–atmosphere interactions between

191 NICAM and MATSIRO during subsequent model forecasts. Here, panel (b) shows the full
192 strongly coupled DA method (cf. Fig. 2g). The image for NICAM was adapted from Satoh et
193 al. (2014).

194 This study considers seven coupled DA experiments (Fig. 2). Referring to Penny and
195 Hamill (2017), we classify these experiments into five categories: Quasi-WCDA, WCDA,
196 Quasi-SCDA, SCDA, and Fully SCDA. Here we introduce identifiers (IDs) indicating which
197 observation type is assimilated for each model. This study defines 'A' and 'L' as representations
198 of the atmospheric and land, respectively. The IDs are defined as follows: 'A_{A×}' represents that
199 assimilating only atmospheric observations to update the atmospheric model; 'A_{AL}' signifies
200 that assimilating both atmospheric and land observations to update the atmospheric model;
201 'L_{A×}' denotes that assimilating only land observations to update the land model; 'L_{×L}' indicates
202 that assimilating only land observations to update the land model; 'L_{AL}' corresponds to that
203 assimilating both atmospheric and land observations to update the land model; finally, 'L_{××}'
204 represents that no observation is assimilated to update the land model.

205 For example, 'A_{A×}L_{××}' indicates that atmospheric observations are used to update the
206 NICAM variables, while no observations are assimilated for the land model (Fig. 2a). This
207 experiment is considered quasi-WCDA and is equivalent to the standard NICAM-LETKF
208 system without SM DA, or the control case (hereafter CTRL). 'A_{A×}L_{×L}' stands for WCDA
209 (Fig. 2b), while 'A_{AL}L_{AL}' signifies Fully SCDA (hereafter Full-SCDA; Fig. 2g). The remaining
210 four experiments are treated as Quasi-SCDA (Figs. 2c and d) and SCDA (Figs. 2e and f).

211 This study designs specific configurations of SCDA and WCDA to investigate whether
212 updating MATSIRO variables through assimilating particular atmospheric observations has a
213 beneficial impact. This investigation aims at finding the best-performing coupled land-
214 atmosphere DA that consists of updates with a beneficial effect for the experimental setting of
215 the present study. The best-performing approach might be different if we use different DA
216 configurations or change the experimental settings, such as resolution and DA frequency.

217

218

219 **Figure 2.** Schematic plots of seven DA experiments for (a) $A_{A\times L\times\times}$ (CTRL; quasi-
 220 WCDA), (b) $A_{A\times L\times L}$ (WCDA), (c) $A_{A\times L\times A\times}$ (quasi-SCDA), (d) $A_{AL\times\times}$ (quasi-SCDA), (e)
 221 $A_{A\times L\times AL}$ (SCDA), (f) $A_{AL\times L}$ (SCDA), and (g) $A_{AL\times AL}$ (Full-SCDA). The vertical axis
 222 represents atmospheric or land variables, and the horizontal axis shows observations. The
 223 shading of variables matches that of the observations used for their updates. White areas with
 224 ‘no’ indicate error correlations that are assumed to be zero in DA. Gray areas with ‘yes’ indicate
 225 error correlations that are included in DA.

226

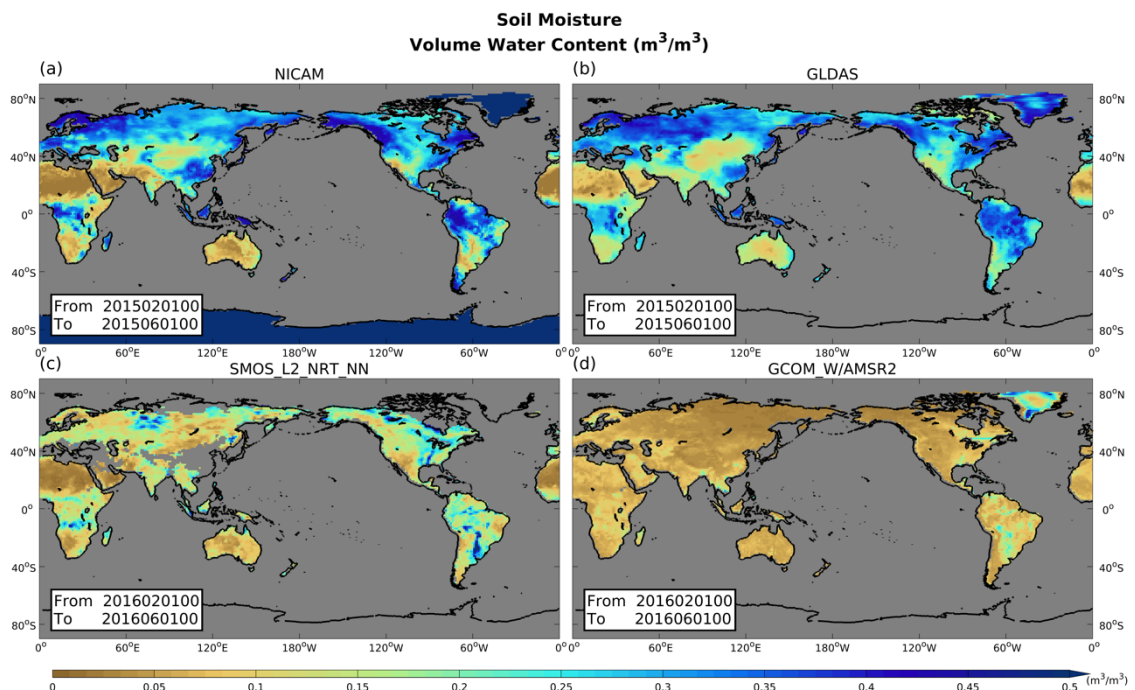

227 *c. Atmospheric data*

228 The original NICAM-LETKF system assimilates conventional observations from the
 229 NCEP operational system (a.k.a. NCEP PREPBUFR), satellite radiance from Advanced
 230 Microwave Sounding Unit-A (AMSU-A), and the near-real-time version of Global Satellite
 231 Mapping of Precipitation (GSMaP_NRT). The data set includes a number of different types of
 232 data: radiosondes, wind profilers, aircraft reports, surface pressure, atmospheric motion vectors
 233 and surface winds derived from satellite observations. The channel selections for satellite
 234 radiances are 6, 7, and 8 for AMSU-A. The stratospheric sensitive channels are not assimilated
 235 in this study, considering relatively low top level of the NICAM in this study (40 km). The
 236 satellite radiance scans and airmass biases are adaptively estimated and corrected at each data

237 assimilation cycle. This experimental setting followed the operationally running NICAM-
 238 LETKF system. In this study, we use these data as atmospheric observations (cf. Table 1 of
 239 Kotsuki et al., 2019a). For further details of the assimilation methods used for these
 240 observations, we refer readers to previous studies (Terasaki et al., 2015; Kotsuki et al., 2017a;
 241 Terasaki and Miyoshi, 2017).

242 *D. Soil moisture data*

243 Satellite instruments can measure several land variables, including SM, surface skin
 244 temperature, and snow depth. Previous studies have found that land surface models tend to
 245 overestimate SM relative to SM data derived from satellite observations (Bindlish et al., 2018).
 246 GLDAS also shows larger SM values than satellite-based data (Bi et al., 2016). The significant
 247 bias between the model-based estimate and observation is unfavorable for DA. Prior to DA
 248 experiments, we compare spatial distributions of climatological SM for NICAM and satellite-
 249 based observations from the Soil Moisture and Ocean Salinity (SMOS; [https://smos-
 250 diss.eo.esa.int/oads/access/](https://smos-diss.eo.esa.int/oads/access/)) and the Advanced Microwave Scanning Radiometer 2 of Global
 251 Change Observation Mission – Water (GCOMW/AMSR-2; <https://lance.nsstc.nasa.gov/amsr2-science/>). We can see that NICAM SM is greatly biased
 252 compared to these satellite-based data (Figs. 3a, c, and d). In contrast, the bias of SM in NICAM
 253 relative to GLDAS is much smaller than that relative to SMOS and GCOMW/AMSR-2.
 254

255
 256

257 **Figure 3.** Spatial patterns of soil moisture (m^3/m^3) for NICAM, GLDAS,
258 SMOS_L2_NRT_NN, and GCOM_W/AMSR2, averaged over February to June in 2015 (a, b)
259 and 2016 (c, d).

260

261 Hoover and Langland (2017) assimilated pseudo-radiosonde observations from an
262 independent atmospheric reanalysis system. They mentioned that assimilating reanalysis data
263 from an advanced system significantly reduced biases in atmospheric temperature and
264 geopotential height. As a first step, this study takes a similar approach and assimilates SM from
265 GLDAS to avoid using satellite observation data which usually contain significant bias.

266 It is generally known that satellite, remote sensing, and model data sets have different
267 mean SM values. Since we do not know the true mean values in remote sensing or model
268 outputs, we cannot attribute these differences in these mean to bias in any specific data source.
269 Satellite retrieval and model averages are determined by the parameters used in the retrieval
270 and surface models, but we also do not know what those parameters should be. Therefore, the
271 standard approach in SM data assimilation is to remove the difference between modeled and
272 observed SM averages, and then assimilate only the temporal anomalies in the observed SM
273 values. Since it is crucial to have unbiased model and observation states to ensure the DA
274 assumption is correct, several processes are proposed (Dee, 2005). For example, Reichle and
275 Koster (2004) suggest a simple method to remove strong biases between satellite-based and
276 model-based data, in which they match the cumulative distribution functions (CDF) of the
277 satellite and model data (a.k.a. CDF matching approach). On the other hand, several previous
278 studies have successfully performed data assimilation without bias correction (e.g., De Lannoy
279 et al., 2007; Bosilovich et al., 2007; Reichle et al., 2010; Honda et al., 2018). For example,
280 Honda et al. (2018) demonstrated that assimilating geostationary satellite infrared radiance
281 observations without bias correction every 10 minutes reduced the bias between the forecast
282 and observations, leading to improved analysis without causing inconsistencies in the model
283 states. Following the success of these previous studies, the present study assimilates SM data
284 without bias correction. As shown later in Section 4a, the bias between the forecast and
285 observation becomes negligible after a one-month spin-up period when SM from GLDAS is
286 assimilated every 6 hours. Consequently, assimilating SM data without bias correction yields
287 improvements in prediction accuracy of atmospheric variables. Since employing bias

288 correction techniques and assimilating real satellite-sensed SM data could potentially lead to
289 further enhancements, such endeavors are important subjects for future studies.

290 We perform QC using flags provided with the satellite observation data. In addition, as
291 applied for PREPBUFR and GSMaP_NRT observations, we simply apply a gross error check
292 for SM in which observations are rejected when the observation-minus-forecast value is greater
293 than 10 times the observation error standard deviation (Terasaki et al. 2015).

294 GLDAS is a research-oriented land surface reanalysis system that produces
295 spatiotemporally continuous global SM data. The GLDAS system integrates a suite of land
296 surface models, which include the Noah, Community Land Model, Variable Infiltration
297 Capacity, Mosaic, and Catchment. These land surface models provide physically-based
298 simulations of surface conditions, and each model has strengths and weaknesses depending on
299 the applications. Among them, this study uses Noah model-based SM data (GLDAS Noah Land
300 Surface Model L4 Version 2.1; Chen et al., 1996; Koren et al., 1999). We assimilate only first-
301 layer SM since satellite measurements cannot observe deep-layer SM. GLDAS provides 3-
302 hourly SM at a spatial resolution of $0.25^\circ \times 0.25^\circ$. As these data are denser than those of
303 NICAM (112-km and 6-hourly resolution), we reduce the data density spatially and temporally.
304 The original SM data are averaged within a NICAM model grid so that each observation
305 corresponds to one model grid point. The original 3-hourly data are also averaged over 6 hours.
306 These spatial and temporal data aggregation processes are carried out simultaneously prior to
307 data assimilation.

308 The GLDAS Version 2.1 simulation is forced with National Oceanic and Atmospheric
309 Administration (NOAA)/ Global Data Assimilation System (GDAS) atmospheric analysis
310 fields (Derber et al., 1991), the disaggregated Global Precipitation Climatology Project (GPCP)
311 V1.3 Daily Analysis precipitation fields, and the Air Force Weather Agency's AGRicultural
312 METeorological modeling system (AGRMET) radiation fields. Because GLDAS uses
313 observed precipitation of GPCP, SM in GLDAS is considered better than that of MATSIRO,
314 which uses precipitation forecasts from NICAM to drive the land surface model. Since SM in
315 NICAM has a large bias against the satellite-based product (Fig. 3), this study assimilates SM
316 from GLDAS as pseudo-observations as Hoover and Langland (2017) and verifies forecasted
317 SM compared to GLDAS.

318

319 3. Experimental setting

320 This study performs 40-member NICAM-LETKF experiments. NICAM ensemble
321 forecasts are performed for 9-hour intervals, and observation data from the last 6-hour period
322 are assimilated. The initial ensemble members of the experiments are obtained from the 1st-
323 40th members of a long-term 128-member NICAM-LETKF experiment (Terasaki et al. 2019).
324 This means the initial ensemble spread of SM relies on initial conditions perturbed by the
325 ensemble NICAM forecasts. Covariance localization in LETKF is applied to the observation
326 error covariance \mathbf{R} so that distant observations have smaller impacts on the analysis (Hunt et
327 al., 2007; Miyoshi and Yamane, 2007). Gaussian functions are used for horizontal and vertical
328 localization, given by:

$$329 \quad f = \exp \left[-\frac{1}{2} \{ (d_h / \sigma_h)^2 + (d_v / \sigma_v)^2 \} \right], \quad (11)$$

330 where f is the localization function and d_h and d_v are the horizontal distance (km) and vertical
331 difference (log(Ps)) between the analysis model grid point and the observation, respectively.
332 Standard deviations (SDs) σ_h and σ_v are 400 km and 0.4 natural log pressure as Terasaki et al.
333 (2019) implemented. The localization function is replaced by zero beyond $2\sqrt{10/3} \cdot \sigma_{h,v}$. Land
334 (atmospheric) observations are assimilated into the atmospheric (land) model using the same
335 vertical localization scale. For land observations, surface pressure (Ps) is assigned for the
336 observed height. This study uses relaxation to prior spread (RTPS; Whitaker and Hamill, 2012)
337 for covariance inflation. For atmospheric variables, the relaxation parameter is set to 0.90,
338 which is determined through sensitivity tests (Kotsuki et al., 2017b). As mentioned in Sec. 2 b,
339 the original NICAM-LETKF method, which assimilates only atmospheric observations, is
340 referred to as the control experiment. These experimental settings have been widely applied in
341 previous NICAM-LETKF experiments (e.g., Kotsuki et al., 2018, 2019a). In addition to
342 atmospheric observations, this study assimilates SM data as hydrological land observations.
343 The observation error SD of SM is estimated at $0.05 \text{ (m}^3 \text{ m}^{-3}\text{)}$ based on the innovation statistics
344 of Desroziers (2005) (cf. appendix A). We perform one control experiment and six SM DA
345 experiments, as shown in the schematic images of Fig. 2.

346 Maintaining the ensemble spread is important in the EnKF. We initially expected that
347 ensemble forecasts could sufficiently maintain the ensemble spreads of MATSIRO variables
348 due to physical coupling with NICAM. However, the ensemble spread of SM in MATSIRO
349 decreased rapidly after initiating assimilation of SM from GLDAS in our preliminary

350 experiment (not shown). We were unable to mitigate this rapid reduction of ensemble spreads
351 even by applying RTPS with relaxation parameter $\alpha=0.90$. This outcome seems to be related
352 to two fundamental challenges: (1) the land models are typically more dependent on external
353 forcing, rather than being modeled as a chaotic dynamical system dependent on initial
354 conditions, and (2) the timescales for dynamical changes in land models are much longer than
355 those in atmospheric models. The latter implies that the land model is likely to have a long
356 memory beyond 6 hours for SM. In the case of assimilating SM with atmosphere-land coupled
357 models, SM observations correspond to the slow mode, and atmospheric variables correspond
358 to the fast mode. Therefore, offline land DA systems usually inflate the ensemble spread by
359 adding random noise to atmospheric forcing or observational data. For example, Reichle et al.
360 (2002) added perturbations to the ensemble forecasting system, specifically to forcing and to
361 the model states variables, to account for sources of model error in the land model forecast to
362 generate an ensemble representative of the model forecast uncertainty. In the current study, we
363 use RTPS to maintain the ensemble spread of SM in MATSIRO to avoid the ensemble
364 becoming too confident. In addition, land DA experiments with the land-atmosphere system
365 would represent model errors to some extent since each land model is driven by different
366 forcing. The relaxation parameter for SM is set to $\alpha=1.00$ so that the analysis ensemble spread
367 is equivalent to the forecast ensemble spread. For further details on creating ensemble spreads
368 for land models, we encourage readers to review the summary presented in Draper (2021).

369 Further, since satellite-borne microwave sensors can measure only surface layer SM,
370 we explore better DA strategies that will be applicable to satellite observations. Thus, we only
371 use SM data in the surface layer (0-0.1 meters) provided by GLDAS. In our experiments,
372 GLDAS SM data are assimilated into the topmost layer of MATSIRO (0–0.05 meters).
373 Although analyzing deeper layers of SM is essential to take advantage of land-atmosphere
374 coupling, this study focuses on the surface layer where feedbacks to the atmosphere would be
375 more pronounced than in deeper layers. Note that the present experimental setting for
376 assimilating GLDAS SM data may result in more significant impacts than the experiments with
377 actual satellite observation intervals.

378 We first perform a spin-up NICAM-LETKF experiment from June to September 2014
379 by assimilating only atmospheric observations. The initial NICAM ensemble conditions are
380 taken from the long-term NICAM-LETKF experiment of Terasaki et al. (2019). DA
381 experiments are performed for 13 months, from 0000 UTC 1 October 2014 to 1800 UTC 30

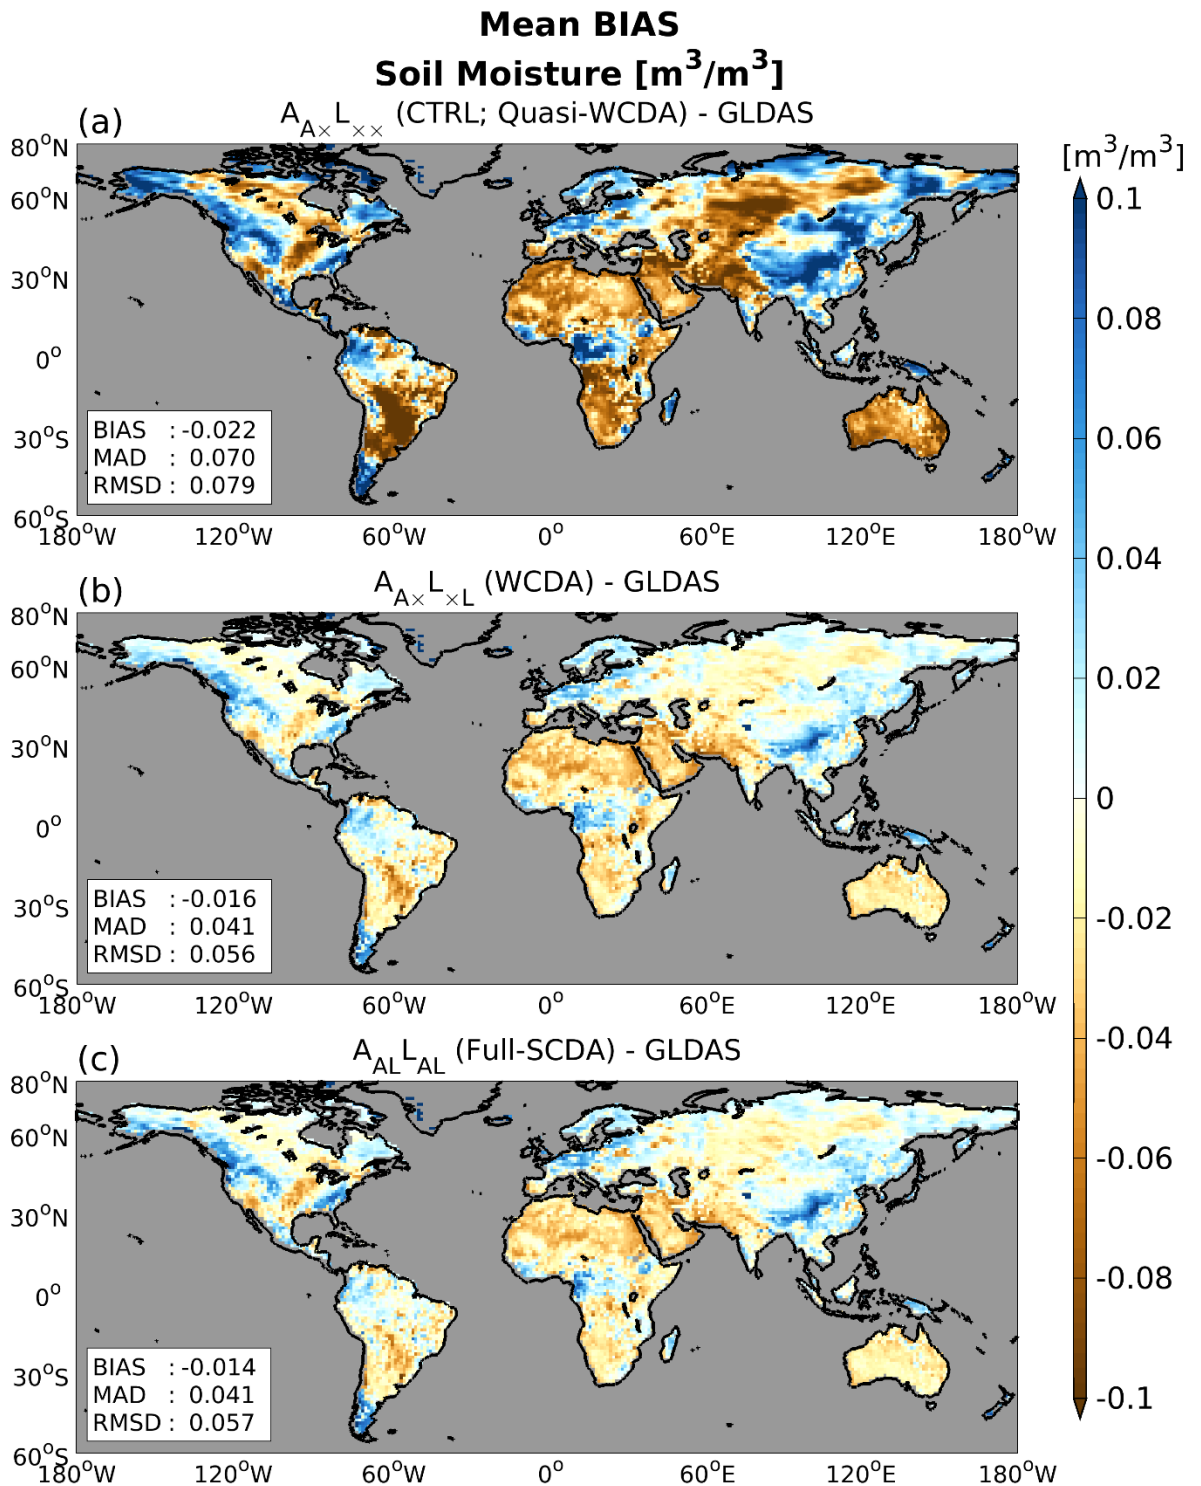

382 November 2015. The first month (October 2014) is considered as a spin-up period, and the
383 results for the latter 12 months are used for validation.

384 In Sec. 4 a, the data are used for validation to check if the assimilation behaves as
385 expected (i.e., the analysis departures of SM are reduced by the assimilation). In addition, we
386 also use SM from ERA5 reanalysis data (Hersbach et al., 2020) as an independent dataset for
387 validation scores. We evaluate atmospheric variables against the ERA5 reanalysis data in Sec.
388 4 b. The analysis of land variables is performed separately from the atmospheric analysis in
389 the ERA5 by assimilating screen-level temperature, dewpoint, and synoptic observations with
390 the optimal interpolation. While the ERA5 assimilates no SM observation, the ERA5
391 assimilates many more satellite observations than the NICAM-LETKF, such as Microwave
392 Humidity Sounder and Advanced Technology Microwave Sounder. Therefore, validating
393 NICAM-LETKF atmospheric fields relative to the ERA5 is reasonable. Furthermore, as
394 described, SM of GLDAS can be considered better than the NICAM-LETKF because it is
395 derived by observed precipitation. Hence, in the following sections, we demonstrate that the
396 assimilation of SM from GLDAS has a beneficial effect on atmospheric fields in NICAM-
397 LETKF, as verified by comparison with ERA5.

398 **4. Results and discussion**

399 *a. Impacts on soil moisture*

400 We first examine the impacts of SM assimilation on MATSIRO. Figure 4 compares the
401 global bias patterns for the prior state of SM at the near-surface layer (i.e., 0-0.05m) relative to
402 GLDAS, averaged over a 12-months period from November 2014 to October 2015. Three
403 panels show the results for $A_{A \times L_{\times \times}}$ (CTRL; quasi-WCDA), $A_{A \times L_{\times L}}$ (WCDA), and $A_{AL}L_{AL}$
404 (Full-SCDA). $A_{A \times L_{\times \times}}$ (CTRL) shows dry biases relative to GLDAS in general, especially in
405 the continents of Africa, South America, Australia, and Central Eurasia (Fig. 4a). Assimilating
406 SM into MATSIRO successfully mitigates these SM biases (Figs. 4b and c). Furthermore,
407 assimilating SM mitigates the wet SM bias in regions where SM is overestimated in $A_{A \times L_{\times \times}}$
408 (CTRL). Therefore, the newly developed coupled land–atmospheric DA system successfully
409 assimilates SM data into MATSIRO, and we confirm the developed DA system works well.
410 These results are expected and not surprising because forecasts are validated using the same
411 data as observations. No notable differences are observed in global bias patterns between
412 $A_{A \times L_{\times L}}$ (WCDA) and $A_{AL}L_{AL}$ (Full-SCDA) in global bias patterns (Figs. 4b and c).

From 2014110100
 To 2015103118

413

414

415 **Figure 4.** Global patterns of 6-hour forecast bias for soil moisture (SM; $\text{m}^3 \text{m}^{-3}$) relative to
 416 GLDAS for (a) $A_{A\times L_{\times\times}}$ (CTRL; quasi-WCDA), (b) $A_{A\times L_{\times L}}$ (WCDA), and (c) $A_{AL}L_{AL}$ (Full-
 417 SCDA), averaged over 12 months from November 2014 to October 2015. The blue and brown

418 colors represent overestimated and underestimated SM values relative to GLDAS, respectively.

419

420

421

422

423 **Figure 5.** Time series of global-mean forecast root mean square differences (RMSDs) for
424 soil moisture (SM; $\text{m}^3 \text{m}^{-3}$) relative to GLDAS. The black, blue, cyan, magenta, green, red, and
425 yellow lines indicate (a) $A_{A \times L_{\times \times}}$ (CTRL; quasi-WCDA), (b) $A_{A \times L_{\times L}}$ (WCDA), (c) $A_{A \times L_{A \times}}$
426 (quasi-SCDA), (d) $A_{AL L_{\times \times}}$ (quasi-SCDA), (e) $A_{A \times L_{AL}}$ (SCDA), (f) $A_{AL L_{\times L}}$ (SCDA), and (g)
427 $A_{AL L_{AL}}$ (Full-SCDA) experiments, respectively. Experiments (a)–(g) correspond to the DA
428 patterns (a)–(g) shown in Fig. 2.

429

430 Figure 5 shows the time series of global-mean root mean square differences (RMSDs) for
431 SM relative to GLDAS. All experiments that assimilate SM have smaller errors in SM than
432 those in $A_{A \times L_{\times \times}}$ (CTRL; Fig. 5a). Although $A_{A \times L_{\times L}}$ (WCDA; Fig. 5b) and $A_{AL L_{AL}}$ (Full-
433 SCDA; Fig. 5g) show reduced errors, no clear difference is apparent between the two
434 experiments. Among the seven experiments, $A_{AL L_{\times L}}$ (SCDA; Fig. 5f) results in the smallest
435 SM error. In this experiment, SM observations are used for updating both NICAM and
436 MATSIRO, whereas atmospheric observations are used only for updating NICAM and not for
437 MATSIRO. Since $A_{AL L_{\times L}}$ (SCDA) results in better SM estimation than $A_{AL L_{AL}}$ (Full-SCDA;

438 Fig. 5g), we can see that updating SM in MATSIRO through assimilation of atmospheric
439 observations have a detrimental impact on SM in the experimental settings of this study.

440 Such detrimental impacts are also found by comparing other cases, such as $A_{A \times L \times L}$
441 (WCDA; Fig. 5b) and $A_{A \times L_{AL}}$ (SCDA; Fig. 5e). The larger error in $A_{A \times L_{AL}}$ (SCDA) than in
442 $A_{A \times L \times L}$ (WCDA) arises from inaccurate covariance estimates between atmospheric
443 observations and land variables due to insufficient ensemble size. Ensemble-based DA can
444 provide spurious error correlations when the ensemble size is small. Assimilating observations
445 based on spurious error covariances generally degrades the analysis results (cf. variable
446 localization of Kang et al. 2011). Moreover, the difference in timescale between the
447 atmospheric and terrestrial models may have a dominant influence, which could be verified by
448 experiments using a short assimilation window. Such further investigation of the assimilation
449 window is essential for future studies of land-atmosphere coupled DA.

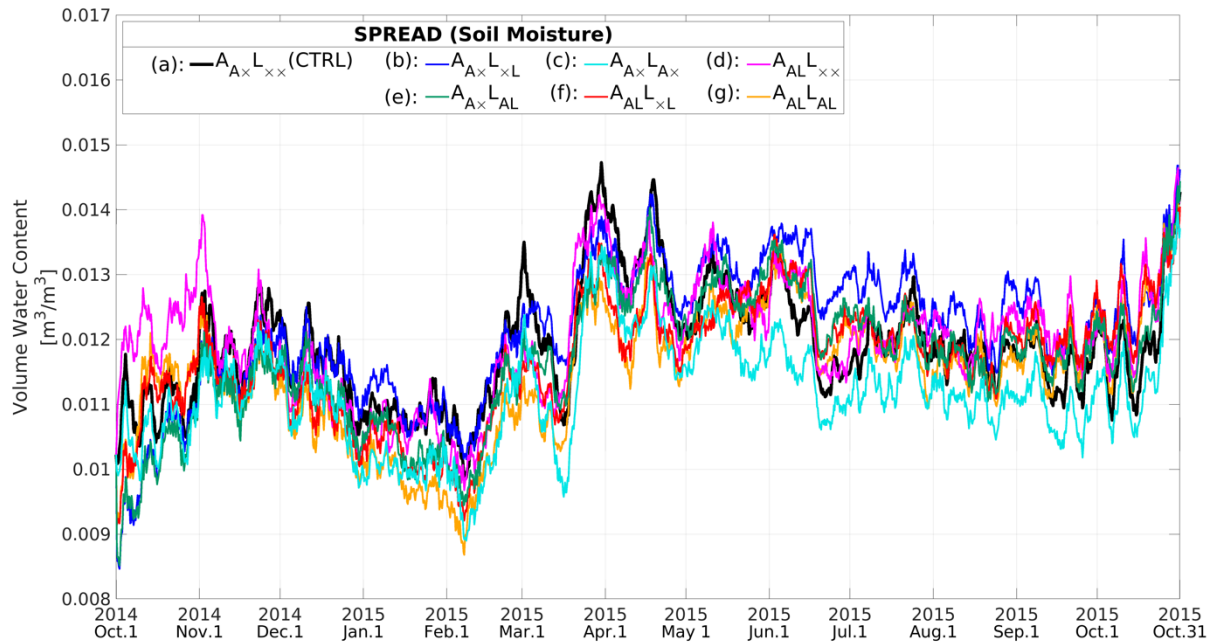

450 $A_{A \times L_{A \times}}$ (quasi-SCDA; Fig. 5c) shows similar RMSDs to those of $A_{A \times L \times \times}$ (CTRL; quasi-
451 WCDA), which implies that atmospheric observations have neither beneficial nor detrimental
452 impacts on updating SM. Because many types of atmospheric observations are assimilated in
453 this study, clarifying impacts of individual observation type is complicated. The results might
454 be changed if we assimilate only one kind of atmospheric observation, such as precipitation
455 data, with the variable localization. Accurate estimation of $(\mathbf{P}^f)_{AL}$ by increasing the number
456 of ensembles might reduce the RMSD of $A_{A \times L_{A \times}}$ (quasi-SCDA). Penny et al. (2019) also faced
457 this kind of problem when assimilating slower ocean observation data into an atmosphere-
458 ocean model with coupled DA. Penny et al. (2019) found that it was more difficult to use slow-
459 mode observations (from the ocean) to update the fast-mode (atmosphere). They overcame this
460 problem by using larger ensembles and increasing the analysis update and observation
461 frequency. As discussed for maintaining ensemble spreads for SM, SM observations
462 correspond to the slow mode and atmospheric variables correspond to the fast mode in our
463 experimental settings. Therefore, applying Penny et al. (2019)'s approach may further improve
464 SCDA.

465 We can say that Fig. 5 represents the error correlation between the SM observations
466 and the atmospheric model variables, showing that it is more reliable than the correlation
467 between the atmospheric observations and the SM variable from the land model. In terms of
468 reducing the errors in SM, the optimal coupled DA method in our experimental setting is
469 $A_{AL}L \times L$ (SCDA). The errors in SM can be reduced by updating atmospheric and land variables

470 through the assimilation of SM. Several previous studies have found that it is important to
471 correct the "upstream" dynamics in the coupled system (e.g., by Sluka et al., 2016). In other
472 words, since the atmosphere strongly drives the land via surface forcing, correcting the
473 atmospheric variables would improve forecasts of the coupled land surface model. From the
474 point of view of the land model, the SM can be updated accurately by assimilating the observed
475 SM directly. Attempting to use fast-varying atmospheric observations for updating SM would
476 lead to suboptimal analysis because of the non-perfect ensemble-based error covariance
477 estimate between atmospheric observations and modelled SM. In contrast, the detrimental
478 impacts of updating atmospheric variables by $(\mathbf{P}^f)_{AL}$ cancel out the beneficial impacts of
479 updating SM by $(\mathbf{P}^f)_{LA}$. Therefore, for our model configuration and DA design, $A_{AL}L_{AL}$ (Full-
480 SCDA) is less effective than $A_{AL}L_{XL}$ (SCDA). This problem might occur because the DA
481 approach degrades the analysis when assimilating atmospheric data into the land model. The
482 approaches for atmosphere-ocean coupled DA suggested by Penny et al. (2019) could solve
483 the problem, which will be an important future subject to improve SCDA even more.

484 Figure 6 shows the time series of ensemble spread of SM. Since RTPS is used with a
485 relaxation parameter of 1.0 for land variables, the ensemble spread does not change during DA.
486 Because no significant difference is observed in the ensemble spreads among experiments, the
487 difference in RMSDs relative to GLDAS must originate from the difference in the update
488 strategy. The ensemble spread of $A_{AX}L_{AX}$ (quasi-SCDA; Fig. 6c) is the smallest among these
489 cases, which means the atmospheric observations have collapsed the spread more than any
490 other configurations. By assimilating the atmospheric observations into the land model, the
491 impact of the land observations becomes less, leading to the detrimental effect observed in
492 those cases. This could also be related to the balance between the errors on the atmospheric
493 observations and the spread of the land model variables. This indicates that the atmospheric
494 observation error should be inflated when applied to the land DA via SCDA. The process filters
495 out the impact of high variability in the atmosphere, similar to adding errors of
496 representativeness in the spatial dimension.

497

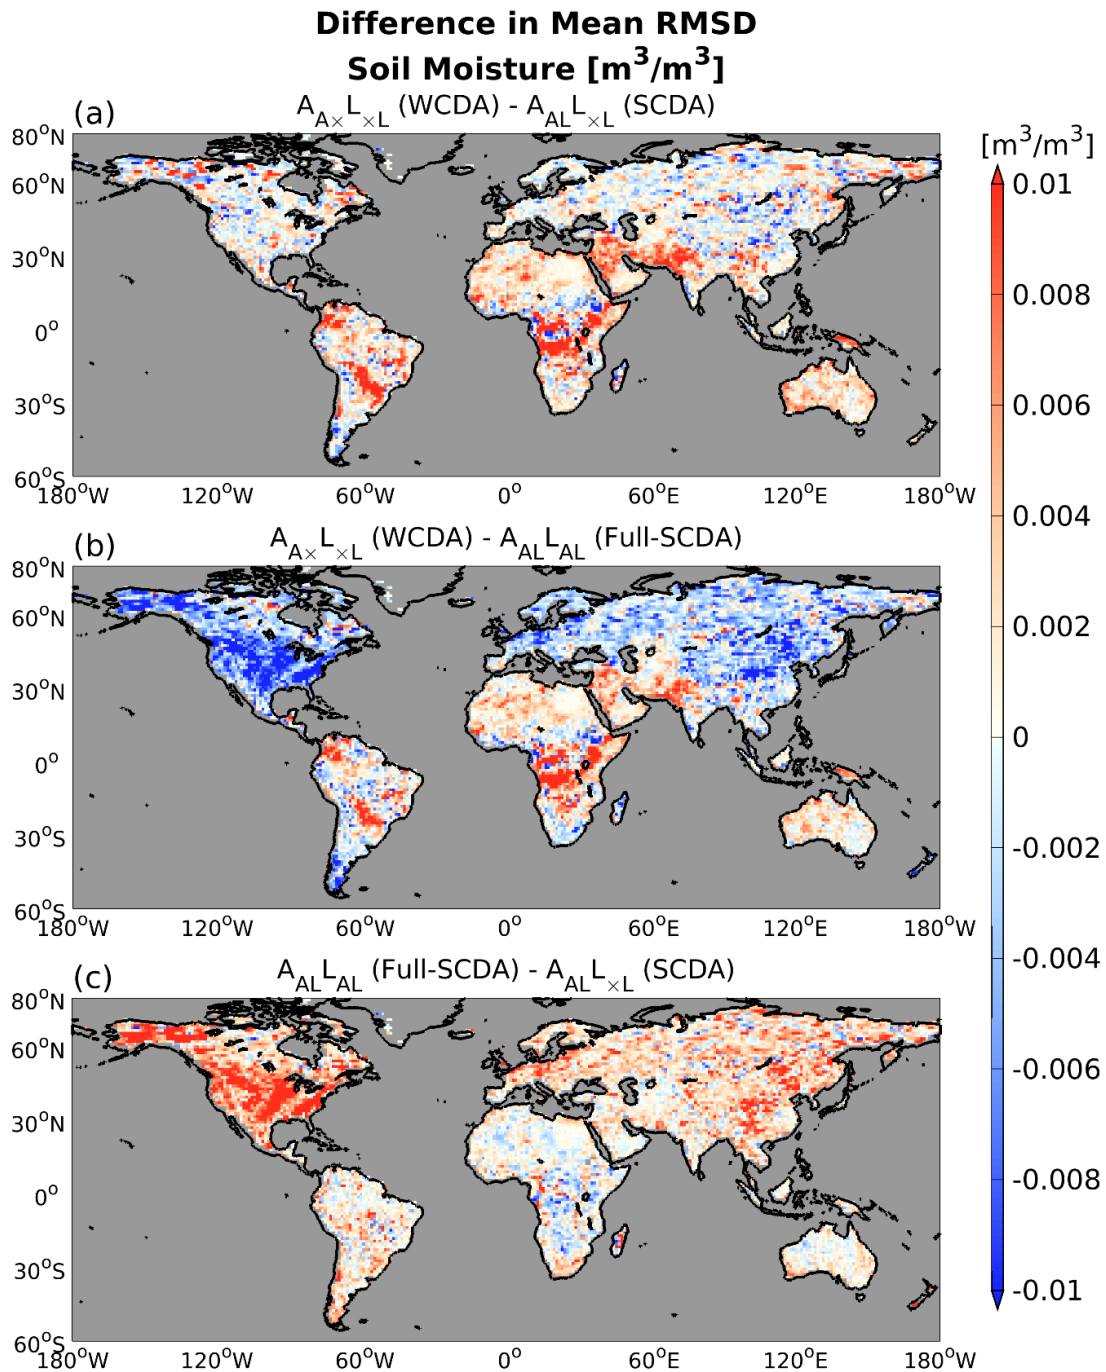

498

499 **Figure 6.** Similar to Fig. 5, but showing forecast ensemble spreads of SM ($\text{m}^3 \text{m}^{-3}$).

500

501 Figure 7 shows the global patterns of differences in analysis RMSDs for SM, averaged
 502 over a 12-month period from November 2014 to October 2015. Here, we discuss three
 503 experiments: $A_{A\times L_{\times L}}$ (WCDA), $A_{AL}L_{AL}$ (Full-SCDA), and $A_{AL}L_{\times L}$ (SCDA), which are the
 504 best three experiments in terms of errors in SM, as shown in Fig. 5. First, we compare $A_{A\times L_{\times L}}$
 505 (WCDA) and $A_{AL}L_{\times L}$ (SCDA). Figure 7 (a) suggests that updating atmospheric variables with
 506 SM DA generally has beneficial impacts on SM. In South America, the Arabian Peninsula, and
 507 India, beneficial impacts are seen in regions where $A_{A\times L_{\times\times}}$ (CTRL) shows a dry bias in SM in
 508 Fig. 4. Additionally, beneficial impacts are apparent in Central Africa, where $A_{A\times L_{\times\times}}$ (CTRL)
 509 has a wet bias in SM. In contrast, SM DA has moderate impacts in North America and Eurasia.
 510 In these areas, $A_{AL}L_{AL}$ (Full-SCDA) performs worse than $A_{A\times L_{\times L}}$ (WCDA; Fig. 7b),
 511 suggesting that assimilating atmospheric observations to update SM in MATSIRO would be
 512 detrimental in the experimental settings of this study. Therefore, eliminating the updates of
 513 MATSIRO with atmospheric observations has beneficial impacts for SCDA (Fig. 7c).

514

From 2014110100
To 2015103118

515

516 **Figure 7.** Global patterns of soil moisture analysis RMSD ($\text{m}^3 \text{m}^{-3}$) relative to GLDAS
 517 averaged over 12 months from November 2014 to October 2015: (a) difference between
 518 $A_{A \times L \times L}(\text{WCDA})$ and $A_{AL \times L}(\text{SCDA})$, (b) difference between $A_{A \times L \times L}(\text{WCDA})$ and $A_{AL \times L}(\text{Full-SCDA})$,
 519 and (c) difference between $A_{AL \times L}(\text{Full-SCDA})$ and $A_{AL \times L}(\text{SCDA})$. Warm
 520 colors indicate that the latter experiments providing smaller scores than the former
 521 experiments, whereas cool colors indicate larger scores of the latter methods.

21

522

523 We also investigate the SM correlations between GLDAS and the results of the
524 experiments (Fig. 8). We can see that the correlation to GLDAS is larger in the regions where
525 positive impacts are observed in Fig. 7. Figure 9 shows the results of the two-sample t-test.
526 Time series of absolute bias of SM analysis relative to GLDAS are sampled from November
527 2014 to October 2015. When the P-values at a point are smaller than 5%, the null hypothesis
528 at the 95% confidence level is rejected, implying a significant difference. By the significance
529 test, we can see the significant differences between the experiments over broad regions. The
530 significant differences between methods $A_{A \times L \times L}$ (WCDA) and $A_{AL \times L}$ (SCDA) are mainly
531 located in the areas where the bias was relatively substantial in Fig. 4a (Fig. 9a). From Fig. 8
532 and Fig. 9, we can reconfirm the points described in the comments about Fig. 7: (1) using SM
533 to update atmospheric variables has positive effects, especially in areas where there are dry
534 biases, (2) areas where there are wet biases are mitigated by SM DA, and (3) updating SM with
535 atmospheric observations has detrimental effects, leading to the results of $A_{AL \times L}$ (Full-
536 SCDA) experiments.

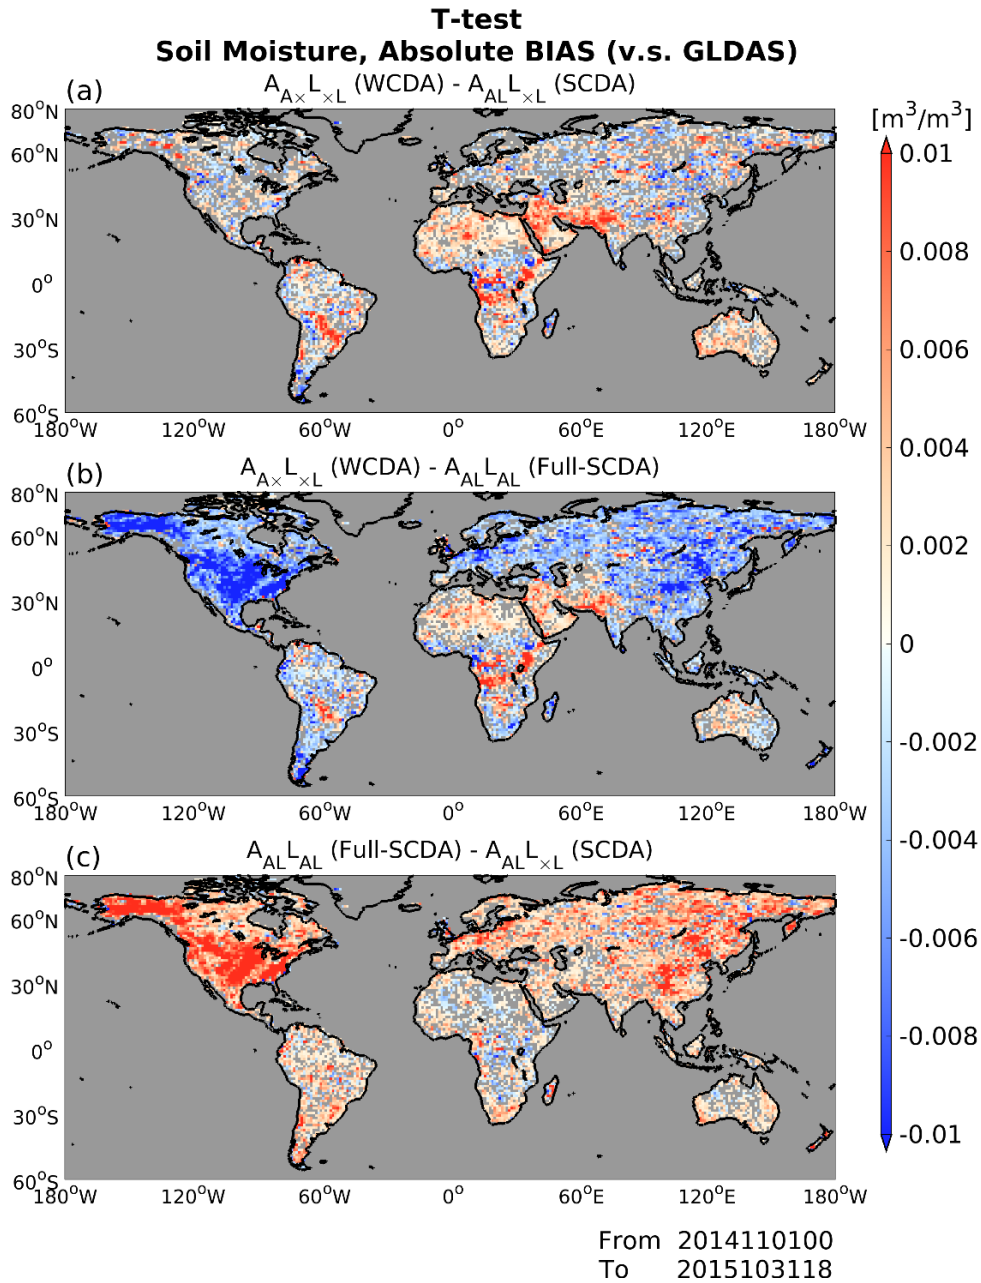

537

538

539 **Figure 8.** Global patterns of soil moisture analysis correlation relative to GLDAS sampled
 540 over 12 months from November 2014 to October 2015: (a) difference between $A_{A \times L \times L}$
 541 (WCDA) and $A_{AL \times L}$ (SCDA), (b) difference between $A_{A \times L \times L}$ (WCDA) and $A_{AL \times AL}$ (Full-
 542 SCDA), and (c) difference between $A_{AL \times AL}$ (Full-SCDA) and $A_{AL \times L}$ (SCDA). Warm colors
 543 indicate that the latter experiments providing smaller scores than the former experiments,
 544 whereas cool colors indicate larger scores of the latter methods.

545

546

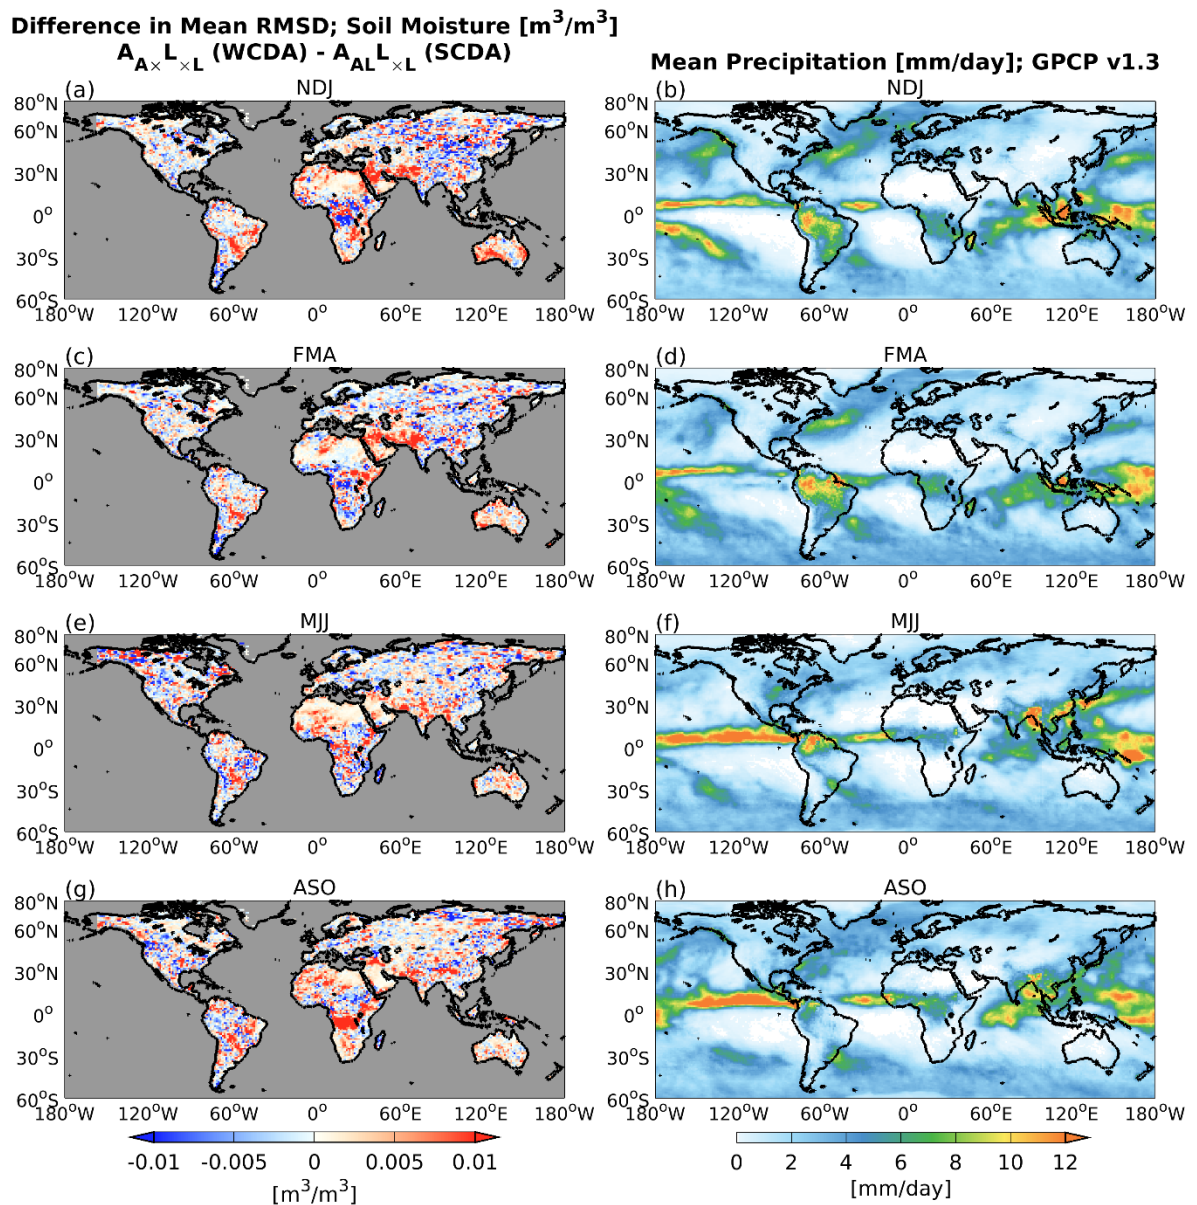

547

548 **Figure 9.** Global patterns of soil moisture analysis absolute bias (m³ m⁻³) relative to
 549 GLDAS: (a) difference between $A_{A \times L \times L}$ (WCDA) and $A_{AL \times L}$ (SCDA), (b) difference
 550 between $A_{A \times L \times L}$ (WCDA) and $A_{AL \times L}$ (Full-SCDA), and (c) difference between $A_{AL \times L}$
 551 (Full-SCDA) and $A_{AL \times L}$ (SCDA). Only the areas where the T-test gives significant
 552 differences (the P-value < 5%) are colored, sampling with time series of soil moisture analysis
 553 from November 2014 to October 2015. Areas without significant differences are grayed out.

554

555 We also investigate the seasonal differences in the relationship between precipitation
556 and SM. Figure 10 compares the difference of SM analysis RMSD relative to GLDAS between
557 $A_{A \times L \times L}$ (WCDA) and $A_{AL \times L \times L}$ (SCDA; Figs. 10a, c, e, and g), with observed precipitation of
558 GPCP version 1.3 (Figs. 10b, d, f, and h). The SCDA experiment shows improvements in the
559 Sahel and equatorial Africa from May to October (Figs. 10e and g) compared to the period
560 from November to April (Figs. 10a and c). These regions are known to be “hotspots” where
561 SM affects precipitation during June–August (Koster et al. 2004). SM assimilation by SCDA
562 would benefit from updating atmospheric variables in the hotspot regions. On the other hand,
563 the distribution of precipitation from November to April tends to shift slightly southwards,
564 resulting in decreased precipitation in previously defined hotspots (Figs. 10b and d). Therefore,
565 the advantages of updating atmospheric variables using SM data are not as evident in these
566 areas in our experiments (Figs. 10a and c). This period includes the summer season in the
567 Southern Hemisphere. For instance, we can confirm a notable increase in precipitation in South
568 America (Figs. 10b and d). Correspondingly, the advantages of using SCDA in that area
569 become more pronounced. The Arabian Peninsula is another region where the advantages of
570 SCDA stand out during this season, despite being an area with scarce rainfall throughout the
571 year and minimal seasonal differences. Therefore, comparison of results from November to
572 April (Figs. 10a-d) with those from May to October (Figs. 10e-h) implies that the locations of
573 the “hotspots” may vary depending on the season.

574 From the above results, it is clear that precipitation and SM are closely related. Given
575 the seasonal variation in precipitation distribution, the regions that would benefit from updating
576 atmospheric variables using SM data shift accordingly.

577

578

579 **Figure 10.** Global patterns of soil moisture analysis RMSD ($\text{m}^3 \text{m}^{-3}$) relative to GLDAS
 580 (panels a, c, e, g) and spatial patterns of observed precipitation of GPCP version 1.3 (mm/day;
 581 panels b, d, f, h). Results are averaged over 3 months: (a, b) November 2014 to January 2015,
 582 (c, d) February to April 2015, (e, f) May to July 2015, and (g, h) August to October 2015. Panels
 583 (a, c, e, g) show the difference between $A_{A \times L \times L}$ (WCDA) and $A_{AL \times L}$ (SCDA). In panels (a,
 584 c, e, g), warm colors indicate that $A_{AL \times L}$ (SCDA) performing better than $A_{A \times L \times L}$ (WCDA),
 585 whereas cool colors indicate worse performance of $A_{AL \times L}$ (SCDA).

586

587 We also use ERA5 SM as an independent dataset for the validation scores, although so far,
588 we have been using GLDAS to verify that the experimental setup works as expected. Fig. 11
589 compares the global patterns of 6-h forecast bias in SM at near-surface layer as in Fig. 4, but
590 relative to ERA5. We can see that $A_{A \times L \times \times}$ (CTRL) shows large dry biases relative to ERA5 in
591 South America and Central Eurasia (Fig. 11a). The dry biases appear mitigated by updating
592 MATSIRO with the SM of GLDAS. Furthermore, NICAM has a large dry bias in the center of
593 the African continent relative to ERA5, which is not the case when compared to GLDAS in
594 Fig. 4. There is a wet bias at the southern and northern ends of the African continent, which
595 increases with the assimilation of SM, but the global-averaged scores show improvements
596 compared to $A_{A \times L \times \times}$ (CTRL; Figs. 11b and c). No notable differences are observed between
597 $A_{A \times L \times L}$ (WCDA) and $A_{AL}L_{AL}$ (Full-SCDA) in global bias patterns (Figs. 11b and c).

598 Figure 12 shows the time series of global-mean RMSDs for SM as in Fig. 5, but relative to
599 ERA5. Similar to the results in Fig. 5, we can find the following features: all experiments that
600 assimilate SM have smaller errors in SM than in $A_{A \times L \times \times}$ (CTRL). $A_{A \times L_{A \times}}$ (quasi-SCDA; Fig.
601 12c) shows larger RMSDs to that of $A_{A \times L \times \times}$ (CTRL) whereas $A_{AL}L_{\times \times}$ (quasi-SCDA; Fig.
602 12d) shows smaller RMSDs than $A_{A \times L \times \times}$ (CTRL). This validation against ERA5 SM also
603 support the previously identified findings: updating atmospheric variables by SM DA is
604 beneficial to improve SM forecasts whereas updating the SM variable by assimilation of
605 atmospheric observations results in detrimental impacts. The differences between the other four
606 experiments, in which SM observations update the MATSIRO variables, are unclear, but they
607 show a significant decrease in RMSDs compared to $A_{A \times L \times \times}$ (CTRL).

608 Lastly, Fig. 13 compares the differences in analysis RMSD of SM relative to ERA5. We
609 can see a meaningful benefit of having atmospheric model variables updated by SM
610 observations where there was a robust dry bias, e.g., in the South American continent (Figs.
611 13a and b). On the other hand, there was originally a wet bias against ERA5, i.e., the Arabian
612 Peninsula and North of the African continent, resulting in a modification effect. Furthermore,
613 a feature not seen in Fig. 7 is that with ERA5 as reference data, there is no significant worsening
614 of the MATSIRO variables by updating them with atmospheric observations (Fig. 13c).

615 The validation results using an independent dataset suggest that the experiments conducted
616 in this study are functioning reasonably well. These findings support the notion that our
617 experiments, which assimilate SM data from GLDAS without bias correction, can perform
618 satisfactorily without violating the underlying assumptions of data assimilation. In this section,

619 the results show that the assimilation of atmospheric observations can lead to detrimental
620 effects on soil moisture analysis. It is crucial to note that this issue stems from the experimental
621 setup rather than statistical aspects. The primary cause of these adverse effects would be the
622 weak dynamical relationship between the lower troposphere and SM. We will explore the
623 issues related to this physical relationship in the subsequent section.

637

638 *b. Impacts on atmospheric field*

639 Here, we investigate the impacts of assimilation of SM on atmospheric variables. Fig.
640 14 shows the global patterns of forecast biases for temperature (K) in the lower troposphere
641 (850 hPa) relative to the ERA5 reanalysis data averaged over 12 months from November 2014
642 to October 2015. Hereafter, we discuss the results of $A_{A \times L \times \times}$ (CTRL) and three coupled DA
643 experiments: $A_{A \times L \times L}$ (WCDA), $A_{AL L \times L}$ (SCDA), and $A_{AL L_{AL}}$ (Full-SCDA). Figure 14 (a)
644 shows that $A_{A \times L \times \times}$ (CTRL) has a warm temperature bias in regions with dry SM biases, as
645 illustrated in Fig. 4 (e.g., South America, Africa, and Australia). In these regions, increasing
646 SM values after assimilation of SM decreases temperature estimates in the lower troposphere
647 (Figs. 14b–d), since more of the incoming solar and longwave radiation is converted to latent
648 heat flux, and less to sensible heat flux with greater SM. Compared to $A_{A \times L \times L}$ (WCDA),
649 however, $A_{AL L \times L}$ (SCDA) and $A_{AL L_{AL}}$ (Full-SCDA) show an overcooling effect for
650 temperature in the continents of Africa and Australia (Figs. 14c and d). This overcooling effect
651 is caused by the assimilation of SM into atmospheric variables in NICAM. The condition and
652 type of soil determine the allocation of energy to latent and sensible heat flux. In areas with
653 sufficient SM, evaporation is limited by the amount of available water, even though more
654 evaporation is energetically possible. In such a case, the ratio of latent heat to sensible heat (i.e.,
655 Bowen ratio) will be determined by the surface temperature. In contrast, in a dry area, the ratio
656 becomes smaller. In addition, the energy balance is led by the turbulent fluxes of sensible,
657 latent heat, and the ground heat flux. The energy transfer from the surface to the atmosphere
658 creates spatial pressure gradients that drive atmospheric circulation at various scales. Due to
659 the factors above, the most appropriate setting was $A_{A \times L \times L}$ (WCDA) in our experiments. There
660 are no remarkable changes in temperature over the ocean among the DA methods.

661

662 **Figure 14.** Global patterns of forecast bias for temperature (K) at 850 hPa relative to ERA5
 663 reanalysis values for (a) $A_{A \times L \times \times}$ (CTRL), (b) $A_{A \times L \times L}$ (WCDA), (c) $A_{A L L \times L}$ (SCDA), and (d)
 664 $A_{A L L \times \times}$ (Full-SCDA), averaged over 12 months from November 2014 to October 2015. Red
 665 and blue colors represent warm and cold biases, respectively.

666

667 Table 1 summarizes the global-mean scores for bias, RMSD, and mean absolute
 668 difference (MAD) in temperature. Tables 1 (a) and (b) show these values averaged over the
 669 ocean and land, respectively. The errors in Table 1 (a) differ less strongly than those in Table
 670 1 (b), showing that assimilation of SM changes the temperature field mainly over land. The
 671 bias values in Table 1 (b) show that $A_{A \times L \times \times}$ (CTRL) has a warm temperature bias over land
 672 in general. Assimilating SM leads to a cooling effect, thereby mitigating the warm temperature
 673 bias. However, $A_{A L L \times L}$ (SCDA) and $A_{A L L \times \times}$ (Full-SCDA) decrease temperature too much,
 674 resulting in a cold bias. Consequently, $A_{A \times L \times L}$ (WCDA) results in the best temperature field
 675 among the four experiments in terms of temperature bias at 850 hPa. Assimilating SM with
 676 $A_{A \times L \times L}$ (WCDA) decreases the average temperature bias by 0.26 K over land. These changes
 677 over land do not propagate significantly to the temperature bias over the ocean.

678

679

680

681 **Table 1.** Averaged scores for bias, mean absolute difference (MAD), and RMSD for
 682 temperature at 850 hPa in Fig. 14. The biases and errors in (a) and (b) are averaged only over
 683 the ocean and only over land, respectively. The smallest errors are indicated by the bold font.

689

690

691

692 We also investigate changes in the precipitation field, focusing on the continent of
693 Africa, where large changes in SM occurs due to SM DA (Fig. 4). Figures 15 (a)–(c) show the
694 spatial patterns of analysis increments for precipitation amount, averaged over 12 months from
695 November 2014 to October 2015. Note that DA can be used for analyzing not only model
696 diagnosed variables (i.e., model state variables) but also other outputs from the model. For
697 example, Kotsuki et al. (2017a) analyzed precipitation using NICAM-LETKF, where
698 precipitation is not part of the initial condition. Here, we compare analysis increments of
699 model-like precipitation (cf. Fig. 3 of Kotsuki et al., 2017a). Since precipitation is classified as
700 an atmospheric diagnosed variable, we observe increments in precipitation during the
701 assimilation of atmospheric observations. The difference in precipitation analysis increments
702 between $A_{A \times L \times \times}$ (CTRL) and $A_{A \times L \times L}$ (WCDA) is insignificant (Figs. 15 a and b). In contrast,
703 precipitation in $A_{AL \times L}$ (SCDA) can be affected by the assimilation of atmospheric and SM
704 observations (Fig. 15 c). In central Africa, where precipitation amount changes significantly
705 with SM DA, the analysis increments shift noticeably. We observe negative analysis
706 increments where SM in $A_{A \times L \times \times}$ (CTRL) is drier, and positive increments when it is wetter.
707 This suggests that coupled land–atmospheric DA performs reasonably, as assimilating SM data
708 increases (decreases) precipitation in areas where NICAM has a dry (wet) bias (Fig. 4a).

709

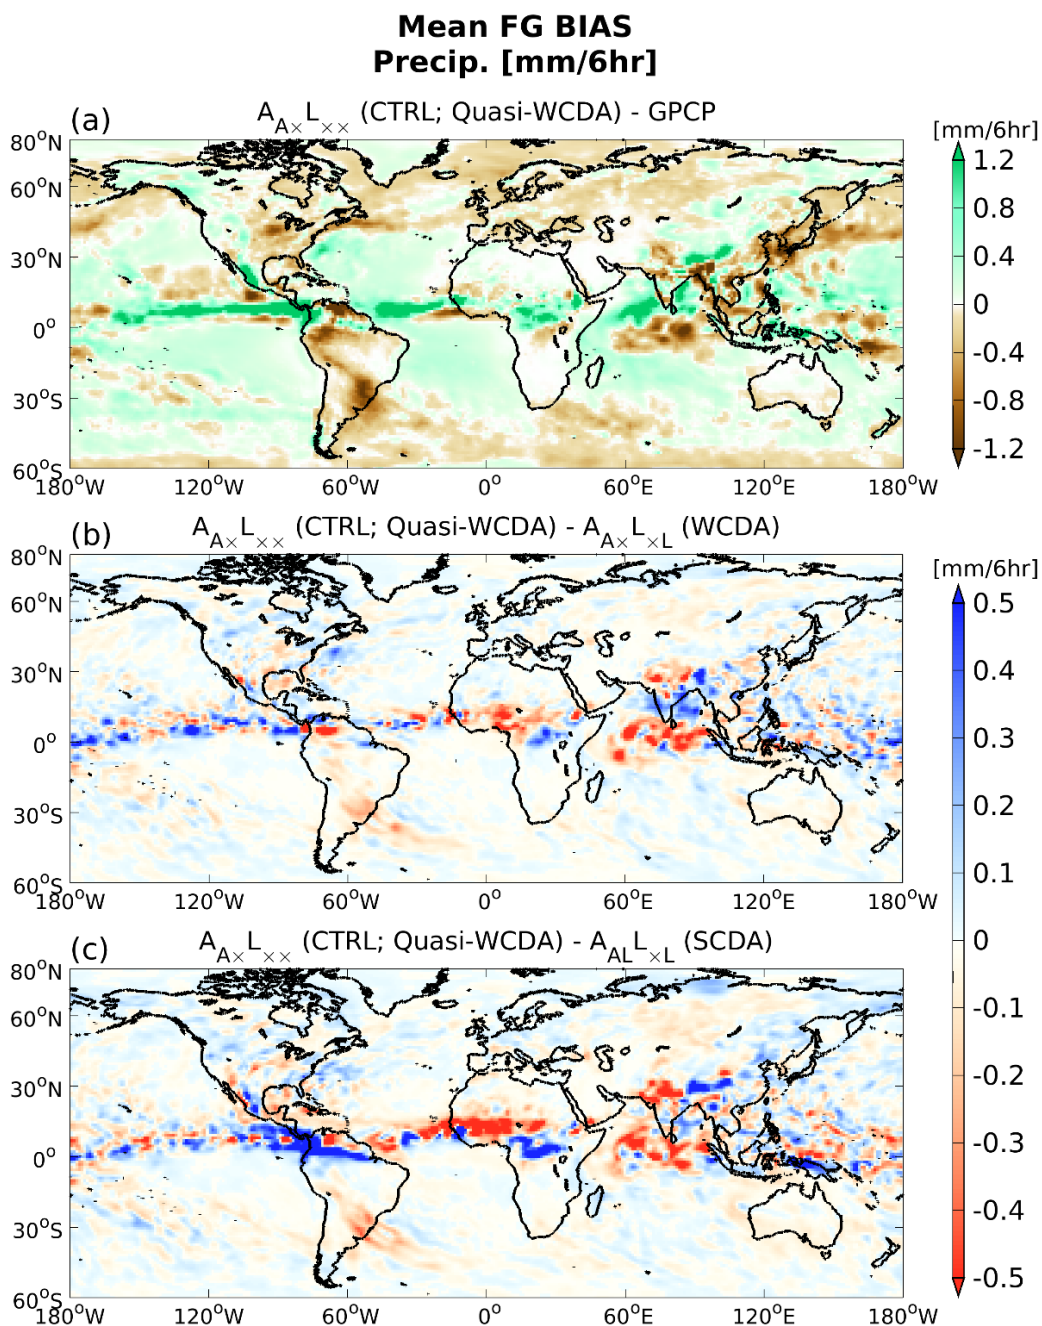

710 **Figure 15.** Spatial patterns of analysis increments for precipitation ($\text{mm } 6\text{h}^{-1}$; panels a–c),
 711 and precipitation forecast biases (panels d–f) and analysis biases (panels g–i) relative to GPCP
 712 version 1.3 ($\text{mm } 6\text{h}^{-1}$), averaged over 12 months from November 2014 to October 2015.
 713 Magenta and cyan colors in (a–c) represent increased and decreased precipitation with DA,
 714 respectively. The green and brown colors in (d–i) represent overestimated and underestimated
 715 precipitation values, respectively, relative to GPCP. Panels (a, d, g), (b, e, h), and (c, f, i) show
 716 the $A_{A \times L \times \times}$ (CTRL), $A_{A \times L \times L}$ (WCDA), and $A_{AL \times L}$ (SCDA) experiments, respectively.

717

718 Spatial patterns of forecast and analysis biases in precipitation relative to GPCP version
719 1.3 estimates are shown in Figs. 15 (d)–(i). GPCP, which provides global precipitation data
720 through the merging of various satellite and gauge datasets, is considered to include the best
721 global precipitation estimates in the climate research community (Kotsuki et al., 2019c). First-
722 guess precipitation in $A_{A \times L \times \times}$ (CTRL) has a positive bias relative to GPCP (Fig. 15d; $+0.159$
723 $\text{mm } 6\text{h}^{-1}$), and this overestimation is intensified in $A_{A \times L \times L}$ (WCDA; $+0.184 \text{ mm } 6\text{h}^{-1}$). In
724 contrast, the first-guess precipitation bias in $A_{AL}L \times L$ (SCDA; $+0.176 \text{ mm } 6\text{h}^{-1}$) is smaller than
725 that in $A_{A \times L \times L}$ (WCDA), although both experiments assimilate SM (Figs. 15e and f). In
726 $A_{A \times L \times \times}$ (CTRL) and $A_{A \times L \times L}$ (WCDA), atmospheric variables are not updated through SM
727 DA. Therefore, differences between the precipitation biases of forecasting and analysis occur
728 due to assimilation of GSMaP_NRT in $A_{A \times L \times \times}$ (CTRL) and $A_{A \times L \times L}$ (WCDA). These two
729 experiments result in differing precipitation biases due to biases in their precipitation forecasts
730 (Figs. 15g and h). Assimilation of GSMaP_NRT slightly reduces the bias in precipitation
731 relative to GPCP (from 0.159 to 0.157 in $A_{A \times L \times \times}$ (CTRL), and from 0.184 to 0.177 in $A_{A \times L \times L}$
732 (WCDA). In contrast, SM DA changes the analysis precipitation in $A_{A \times L \times L}$ (WCDA). $A_{AL}L \times L$
733 (SCDA) shows the smallest bias in analysis precipitation. That is, updating atmospheric
734 variables with SM data plays an important role in improving the accuracy of precipitation.
735 Compared to $A_{A \times L \times \times}$ (CTRL), one of the reasons for the larger bias in the $A_{A \times L \times L}$ (WCDA)
736 and $A_{AL}L \times L$ (SCDA) is due to increased rainfall in areas where NICAM has the dry bias.
737 Originally, NICAM overestimates precipitation (Kotsuki et al., 2019; Fig. 6). Improvements in
738 soil moisture may have reinforced the bias, which leads to worse scores in those cases. It can
739 be said that an improvement of the model bias contained in NICAM is necessary to solve this
740 problem.

741 Figure 16 compares the forecast biases in precipitation relative to GPCP averaged over
742 3 months from June to August 2015. We selected this period to explore SM-atmosphere
743 coupling, as suggested by Koster et al. (2004). Figure 16 (a) shows that NICAM tends to
744 overestimate precipitation in convergence regions at low latitudes (0°N – 10°N) and
745 underestimate precipitation in South America and Southeast and East Asia. Figures 16 (b) and
746 (c) show changes in the precipitation forecasts of $A_{A \times L \times L}$ (WCDA) and $A_{AL}L \times L$ (SCDA). The
747 assimilation of SM affects precipitation mainly at low latitudes. As mentioned in Fig. 10,
748 Koster et al. (2004) found “hotspots” where SM affects precipitation during June–August.
749 Koster et al. (2004) noted that the initial condition of SM was sensitive to rainfall predictability

750 over the North American Great Plains, equatorial Africa, and India (cf. Fig. 1 of Koster et al.,
 751 2004). These areas correspond to the locations where forecast precipitation differed sharply
 752 from SM DA, as shown in Figs. 16 (b) and (c), particularly for the Sahel, equatorial Africa,
 753 and India. When comparing $A_{AL \times L}$ (SCDA) with $A_{A \times L \times L}$ (WCDA), coupled DA shows
 754 stronger impacts in hotspots where the precipitation field is sensitive to the initial condition of
 755 SM.

From 2015060100
To 2015083118

756

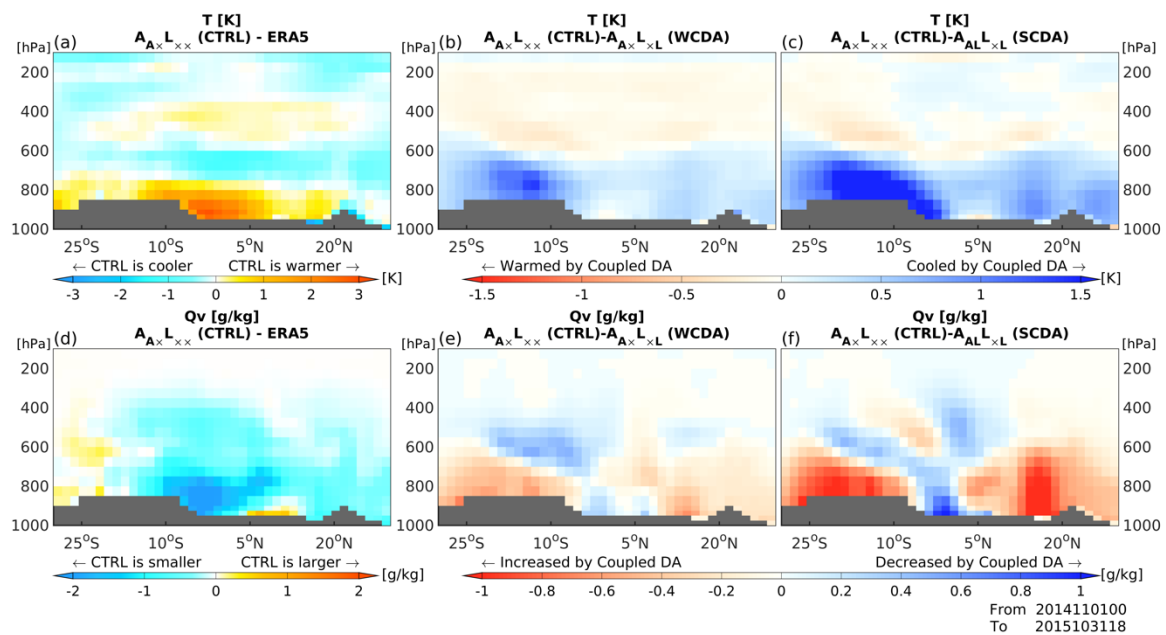

757

758 **Figure 16.** Spatial patterns of changes in precipitation ($\text{mm } 6\text{h}^{-1}$) averaged over 3 months
759 from June to August 2014. Panels (a), (b), and (c) show the difference between
760 $A_{A \times L \times \times}$ (CTRL) and GPCP, $A_{A \times L \times \times}$ (CTRL) and $A_{A \times L \times L}$ (WCDA), and $A_{A \times L \times \times}$ (CTRL)
761 and $A_{AL \times L}$ (SCDA), respectively. The green and brown colors in (a) represent overestimated
762 and underestimated precipitation values relative to GPCP, and the red and blue colors in (b, c)
763 represent increased and decreased precipitation values with SM DA, respectively.

764

765 Figure 17 shows vertical cross-sections of forecast biases for temperature and vapor
766 mixing ratio (Q_v) relative to ERA5 reanalysis data along 20°E over the continent of Africa,
767 averaged over 12 months from November 2014 to October 2015. $A_{A \times L \times \times}$ (CTRL) generally
768 shows a warm temperature bias and a dry humidity bias near the land surface (1000–800 hPa).
769 With the assimilation of SM, $A_{A \times L \times L}$ (WCDA) and $A_{AL \times L}$ (SCDA) show decreases in
770 temperature of the lower troposphere at latitudes where $A_{A \times L \times \times}$ (CTRL) has a warm bias (Figs.
771 17 b and c). Since the vertical layers of NICAM are almost the same as those of the ERA5, the
772 cooling impacts would not be attributed to the difference in vertical resolutions between
773 NICAM and ERA5. $A_{A \times L \times L}$ (WCDA) propagates the impacts of SM DA for atmospheric
774 variables through the interaction between NICAM and MATSIRO during model time
775 integrations. In addition, $A_{AL \times L}$ (SCDA) updates atmospheric variables directly through SM
776 DA, which means $A_{AL \times L}$ (SCDA) alters atmospheric variables both directly and indirectly.
777 Therefore, $A_{AL \times L}$ (SCDA) lowers temperature too much due to the strong interaction between
778 SM and atmospheric variables (Fig. 17 c). Figure 17 (d) shows that most land surface areas
779 have dry Q_v biases relative to the ERA5. This corresponds to the locations where
780 $A_{A \times L \times \times}$ (CTRL) exhibits a moist bias against GLDAS (Fig. 4 a). As shown in Fig. 4, the
781 coupled DA improves this in those areas, which also leads to an enhancement in the Q_v bias in
782 that region. As the moist bias relative to GLDAS in that area is improved through the SM DA,
783 the bias in Q_v relative to ERA5 in that area is also improved by coupled assimilation. $A_{A \times L \times L}$
784 (WCDA) and $A_{AL \times L}$ (SCDA) correct for the bias caused by increased or decreased Q_v near
785 the surface using SM DA (Figs. 17 e and f). The change for Q_v in $A_{AL \times L}$ (SCDA) is larger
786 than that in $A_{A \times L \times L}$ (WCDA). This is because, as previously mentioned, $A_{AL \times L}$ (SCDA)
787 make larger adjustments to atmospheric variables compared to $A_{A \times L \times L}$ (WCDA).

788

789

790 **Figure 17.** Vertical cross-sectional plots of differences in (a–c) temperature (K) and (d–f)
 791 water vapor mixing ratio (g kg^{-1}) averaged over 12 months from November 2014 to October
 792 2015 along 20°E over the continent of Africa. Panels (a, d), (b, e), and (c, f) show the
 793 differences between $A_{A \times L_{\times \times}}$ (CTRL) and the ERA5 reanalysis, $A_{A \times L_{\times \times}}$ (CTRL) and $A_{A \times L_{\times L}}$
 794 (WCDA), and $A_{A \times L_{\times \times}}$ (CTRL) and $A_{AL_{\times L}}$ (SCDA), respectively. The vertical and horizontal
 795 axes show the pressure level from 1000 to 100 hPa and the latitude, respectively.

796

797 5. Conclusions

798 This study aims to explore the optimal coupled land–atmospheric DA method for
 799 improving weather forecasts through the assimilation of hydrological observations. We
 800 implement a coupled land–atmospheric DA into the NICAM-MATSIRO model and
 801 assimilated SM data from GLDAS. We perform a series of coupled DA experiments, including
 802 weakly and strongly coupled DA, and reach the following conclusions.

803 The assimilation of SM successfully mitigates SM biases. Updating SM by assimilating
 804 atmospheric observations can have detrimental impacts on SM, due to spurious error
 805 correlations between atmospheric observations and land model variables caused by insufficient
 806 ensemble size, and the difference in timescale between the atmospheric and land models. In
 807 contrast, updating the atmospheric model variables by assimilating SM observations has
 808 beneficial impacts on SM, implying that the error correlation between SM observations and

40

809 atmospheric model variables is more reliable. Consequently, the optimal coupled DA method
810 in this study is $A_{AL}L_{\times L}$ (SCDA), in which atmospheric and SM data are used to update the
811 atmospheric variables in NICAM, but only SM data are used to update the SM variable in
812 MATSIRO. The results of this study indicate that $A_{AL}L_{AL}$ (Full-SCDA) is less effective than
813 $A_{A\times L}L_{\times L}$ (WCDA), which is caused by sampling errors and/or insufficient localization of the
814 ensemble background-error covariance matrix. As Penny et al. (2019) have shown,
815 experiments with a simple model to examine several factors in detail, such as the number of
816 ensemble members, the scale of localization, the spread of the ensemble of initial members,
817 and the frequency of coupling intervals, would yield very important information. With
818 adequate settings, such as proposed by Penny et al. (2019), the experiments with $A_{AL}L_{AL}$ (Full-
819 SCDA) might give a superior performance. In addition, the difference in dynamical timescales
820 between the atmospheric and land models may possibly have a dominant influence. Using a
821 shorter DA window with more linear cross-domain dynamics could be useful to investigate if
822 this would help improve the impact of the $A_{AL}L_{AL}$ (Full-SCDA). This will be an important
823 future study. Further, one possible reason why $A_{AL}L_{AL}$ (Full-SCDA) did not always show
824 optimal results in the current study could be due to the poor and complex physical linkages
825 between the lower troposphere and soil moisture. This problem has reasonably positive effects
826 on the atmospheric field but often results in poor soil moisture analysis. The results presented
827 in this study seem to indicate that this may be the case for $A_{AL}L_{AL}$ (Full-SCDA).

828 We demonstrate that precipitation and SM are closely related. Given the seasonal
829 variation in precipitation distribution, the regions that would benefit from updating atmospheric
830 variables using SM data shift accordingly. Assimilating SM provides a proper temperature
831 estimation for the lower troposphere in areas with a dry SM bias and a warm atmospheric bias.
832 This effect occurs because more incoming solar and longwave radiation was converted to latent
833 heat flux and less converted to sensible heat flux with increased SM. However, assimilating
834 SM into atmospheric model variables lead to overcooling effects in regions such as the
835 continents of Africa and Australia. Furthermore, estimating precipitation based on SCDA is
836 beneficial in Africa. Coupled DA has stronger impacts on precipitation forecasts in hotspots
837 where the precipitation field is sensitive to the initial condition of SM.

838 This study demonstrates the potential for improving SM prediction using the NICAM-
839 LETKF system by assimilating SM in strong coupled DA. SM is an important variable in land
840 surface models, and its improvement can lead to better hydrological predictions such as

841 droughts and floods. However, it is still unclear what atmospheric variables should be updated
842 using each land observation. Therefore, future studies will further investigate the effect of
843 variable localization for other land observations. When updating SM in MATSIRO with
844 atmospheric observations, we obtain unfavorable results due to errors in estimating the error
845 covariance between land model variables and atmospheric observations. The issue is thought
846 to be caused by experimental settings, rather than statistical aspects, due to the poor physical
847 relationships between the lower troposphere and SM. SM behavior is often highly localized
848 due to spatial differences such as soil texture, topography, and vegetation. Therefore, most
849 NWP centers use a point-wise analysis of SM, without considering the horizontal background
850 error covariance between grid points. The 40 ensemble members used in this study are close to
851 the number used in operational NWP centers, but using a larger number of ensembles could
852 lead to useful conclusions by evaluating the differences in performance between WCDA and
853 SCDA. Furthermore, using a large ensemble could be beneficial for understanding variable
854 localization more accurately by improving covariance estimation between components. In this
855 study, land observations are assimilated into the atmospheric model using the same vertical
856 localization scale as the assimilation of atmospheric observations. Using a smaller localization
857 scale in a limited ensemble size could help update atmospheric variables with SM assimilation
858 by reducing errors in the error covariance estimates. Furthermore, while this study uses SM
859 data based on GLDAS, assimilating satellite-derived SM data is an important direction for
860 future research. When actual GCOMW/AMSR-2 satellite observation data are assimilated, the
861 atmospheric field deteriorates significantly due to the assimilation of SM (not shown). This
862 suggests that limitations exist in the data assimilation method used in this study and that
863 technical measures, such as CDF matching preprocessing, may be necessary to assimilate
864 actual observation data successfully. Finally, it is found that resolution of about 100 km is very
865 coarse to simulate SM accurately. Note that the assimilation of GLDAS pseudo soil moisture
866 data is not a realistic operational setting, as it is likely to have much better spatial and temporal
867 coverage than real satellite observations. When actual observation data are assimilated at this
868 resolution, the representation error becomes large and can cause a problem. In addition to using
869 actual satellite observation data, using higher-resolution models is an important future
870 direction.

906

907

This study diagnoses the observation error SD of SM by using innovation statistics (Desroziers et al., 2005). The innovation statistics is given by:

908

$$(\sigma_{estimation}^o)^2 = \langle (y^o - H\bar{x}^a)(y^o - H\bar{x}^f) \rangle, \quad (A1)$$

909

910

911

912

913

914

where, σ^o is the observation error SD. Subscript *estimation* means the estimation by the innovation statistics. The bracket $\langle \cdot \rangle$ denotes the statistical expectation. Here, we assumed the observations error SD is globally constant and time independent for SM (Rodríguez-Fernández et al., 2019). With NICAM-LETKF, we performed preliminary WCDA and SCDA experiments over two months from October to November 2014, and used later one month period data for the innovation statistics. Here we introduce a measure *factor*, given by

915

$$Factor = \sigma_{estimation}^o / \sigma_{prescribed}^o, \quad (A2)$$

923

924

where the subscript *prescribed* denotes the prescribed observation error SD of SM used in the preliminary experiments. If the prescribed SD is optimal, then the diagnosed *factor* approaches 1.0. Table A1 summarizes the prescribed observation error SD and *factor* values for five different observation SDs with assimilation of GLDAS SM. As noted by Ménard et al. (2009), when the prescribed observation error SD is too small, the estimated observation error SD is underestimated, whereas large SDs can lead to overestimation. Based on these preliminary experiments, this study set the SM observation error SD at $0.05 \text{ (m}^3 \text{ m}^{-3}\text{)}$, which gave the *factor* value closest to 1.0 among the preliminary experiments.

925

926

927

Table A1. Observation error SD diagnosed using innovative statistics. “Factor” is the ratio of estimated error SD to the prescribed value (Eq. A2). The diagnostic values from $A_{\times}^{\times}L_{\times}^{-}$ (WCDA) and $A_{\times}^{\times}L_{\times}^{\times}$ (SCDA) averaged over 2 months are shown.

928

929

Prescribed Obs.	Factor	
Error SD ($\text{m}^3 \text{ m}^{-3}$)	$A_{\times}^{\times}L_{\times}^{-}$ (WCDA)	$A_{\times}^{\times}L_{\times}^{\times}$ (SCDA)
