7 **Abstract**

8 An unusually severe hurricane (Louisbourg Storm) struck Nova Scotia Canada in 1757. Historic  
9 records describing storm conditions as well as damage to ships and coastal fortifications indicate  
10 an intensity beyond any modern (post-1851) Atlantic cyclones striking the same region, yet this  
11 storm struck during a cold climate period known as the Little Ice Age (LIA). Its track and timing  
12 coincided with a British naval blockade of a French fleet at Fortress Louisbourg during the Seven  
13 Years' War (1756-1763). This provides a unique opportunity to explore growing scientific  
14 evidence of heightened storminess in the North Atlantic despite a colder climate expected to  
15 suppress hurricane intensification but which research is increasingly showing to have supported  
16 North Atlantic storms of exceptional strength. Weather attributes extracted from the logs of  
17 naval vessels scattered by the Louisbourg Storm provided multiple hourly observations recorded  
18 at different locations. Wave height and wind force estimates at ship locations were compared to  
19 extreme storm surge heights calculated for Louisbourg Harbour and a shipwreck site south of  
20 Fortress Louisbourg. Comparing these metrics to those of modern analogs that crossed the same  
21 bathymetry reflects landfall intensity consistent with a powerful major hurricane. Historical  
22 records show this storm originated as a tropical cyclone at the height of hurricane season and  
23 intensified into the northern midlatitudes along the Gulf Stream. Its intensity at landfall is

24 consistent with established seasonal climatological models where highly baroclinic westerlies  
25 driven by autumn continental cooling encounter intensifying north-tracking tropical cyclones  
26 fueled by sea surface temperatures that peak in autumn. Stronger seasonal contrasts from earlier  
27 and colder continental westerlies in the Little Ice Age (LIA) may have triggered explosive  
28 extratropical transition from a large hurricane resulting in a more severe strike. It suggests that  
29 tropical cyclones lasting days to weeks and the conditions that generate them are likely masked  
30 by cooler historic mean-annual to multi-decadal LIA climate reconstructions. Predictions of  
31 warmer midlatitude sea surface temperatures could see powerful hurricanes intensify into higher  
32 latitudes later into the fall, potentially recreating the strong contrasts that triggered the intensity  
33 of the Louisbourg Storm.

#### 34 **1.0 Introduction**

35 On September 25, 1757, a powerful hurricane struck the coast of Cape Breton Island,  
36 Nova Scotia, Canada (Fig. 1). There would have had no record of the ‘Louisbourg Storm’ had it  
37 not coincided with a British naval blockade of France’s Fortress Louisbourg during the Seven  
38 Years’ War (1756-1763). Three French naval squadrons at Louisbourg and the blockading

39

40 **Figure 1.** Study location in Nova Scotia, Canada. Arrow length and orientation represents the  
 41 distance and direction traveled by the British fleet on September 21-26, 1757. September 25 and  
 42 26 show the path of the *Invincible* south of the wider dispersal of the British fleet after being  
 43 scattered by the storm (dotted oval). The storm's location off New England is estimated (off  
 44 map). The estimated storm track (dashed line) shows eye locations for the dates shown Inset  
 45 shows the study area relative to the North Atlantic and the hurricane track based on historic  
 46 records showing its progressive northward translation seaward of (1) Florida (no date), (2) North  
 47 Carolina (September 23), (3) New England (September 24) and (4) Cape Breton Canada  
 48 (September 25-26). Fort Cumberland is 70 km toward 293 Azimuth.

49 British fleet placed 49 sailing battleships and warships in the path of a storm descriptions of  
 50 damage to ships and coastal infrastructure, severe flooding from rainfall and extreme storm surge  
 51 suggest was more intense than any landfalling storm in Canadian waters since modern records

52 began in 1851 (Landsea et al., 2004, Finck, 2015). This suggests it had the intensity of a major  
53 hurricane at landfall (Category 3+ on the Saffir-Simpson Hurricane Wind Scale) yet it struck  
54 during the colder climate of the ‘Little Ice Age’ (LIA; c1300-1850).

55         Hurricanes are fueled by sea surface temperature (SST) over 28C. They rapidly lose  
56 energy as the move north over cooler midlatitude waters, and many tropical cyclones undergo  
57 extratropical transition which releases tropical energy at increasingly higher latitudes later in  
58 hurricane season (Hart and Evans, 2001). Modern tropical cyclone intensity is characterized in  
59 real time with instruments carried by aircraft, satellites and at ground stations. In contrast, pre-  
60 industrial metrics must be derived from historical observational records. Subjective interpretation  
61 and geographic bias can make them less reliable than instrumental data (e.g., Jones and Mann  
62 2004), yet they offer a temporal resolution unavailable in scientific proxies, and they straddle the  
63 end of the LIA and the rise of modern anthropogenic emissions. Oliver and Kington (1970) and  
64 Lamb (1982) first explored their suitability for weather research. Naval logbooks were  
65 subsequently found to be a superior source of historical weather data given that hourly ship  
66 observations were systematically recorded in real time with a consistent terminology. Logbook  
67 data have been compiled to assess historical atmospheric circulation patterns (e.g., Garcia et al.,  
68 2001, Garcia-Herrera et al., 2005a, Wheeler et al., 2010, Barriopedro et al., 2014). CLIWOC, the  
69 Climatological Database for the World’s Oceans, was compiled from historical British, French,  
70 Dutch and Spanish naval logbooks. It established a common historical wind force terminology to  
71 document ocean surface atmospheric circulation patterns between 1750 and 1850 (Garcia-  
72 Herrera et al., 2005b).

73         To date, pooled historical naval records have been used to identify longer-term regional  
74 circulation patterns and extend the multidecadal climate signal into the industrial period (e.g.,

75 Garcia-Herrera et al., 2005a, 2005b, Wheeler et al., 2010, Barriopedro et al., 2014). In contrast,  
76 this study takes advantage of an unusual concentration of warships in the path of a single  
77 hurricane to characterize its intensity. It seems counterintuitive that the colder LIA climate would  
78 generate more powerful midlatitude Atlantic cyclones than in the modern era, yet historical  
79 records show the LIA to be generally ‘stormier’ with unusually powerful midlatitude hurricanes  
80 despite conditions that dampen hurricane energy. Donnelly et al.’s (2001) historic storm  
81 reconstruction from Mattapoissett Pond, Massachusetts, and Oliva et al.’s (2018) historic storm  
82 reconstruction from Robinson Lake, Nova Scotia, are among a growing number of proxy studies  
83 showing that major Atlantic cyclones struck the northeastern seaboard of North America in the  
84 LIA. Since winter extratropical cyclones known as Nor’easters cannot be differentiated from  
85 Atlantic tropical cyclones and their extratropical derivatives from proxy data alone, historical  
86 records can constrain the timing of midlatitude hurricanes and tropical storms.

87 This study utilizes a unique historical data set to characterize the intensity of the  
88 Louisbourg Storm using spatial and temporal weather metrics extracted from ship logbooks of  
89 both the English and French fleets, British Admiralty records and official documents of both  
90 nations, and compares the derived storm metrics to those of modern systems that tracked across  
91 the same bathymetry. Characterizing its intensity tests historical descriptions of an unusually  
92 severe storm and may help establish a more thorough understanding of LIA hurricane  
93 climatology.

## 94 **2.0 Methodology**

### 95 *2.1 Historical Records*

96 Eighteenth century navigation and weather data were entered hourly in the daily logs of  
97 naval vessels, resulting in reliable records suitable for historical climate research. A noon

98 sighting of the sun fixed latitude and marked the start of the sea day. Britain adopted the  
99 Gregorian calendar in 1752 so dates in logs used for this study did not require correction. In 1757  
100 a local meridian was used to determine longitude, deduced from logs to have been based on  
101 Louisbourg Lighthouse (Fig. 2).

102         Historical British Admiralty Correspondence and Papers (ADM1/481, 1488, 2294)  
103 covering storm damage to British vessels on the ‘Halifax Station’ in 1757 and Fleet Lists  
104 (ADM8/31, 32) are preserved at the National Archives at Kew (UK), as are Royal Navy Master’s  
105 (ADM 51/409, 633,1075) and Captain’s (ADM 52/578,819,1064) logbooks. Lieutenant’s logs  
106 (ADM51) kept at the National Maritime Museum, Greenwich, were often incorporated into  
107 Captain’s logs with addenda. Master’s and Captain’s logs of the Royal Navy warships *Invincible*,  
108 *Windsor*, *Sunderland*, *Eagle*, *Terrible*, *Grafton*, *Newark*, and *Captain*, plus ancillary official  
109 correspondence, were used in this study. All logs were consistent in content and format. Letters  
110 and logbook entries written in ink were copied from cursive in multiple handwriting styles to a  
111 more readable format, interpreted, compiled into a time sequence and cross referenced. Logs  
112 from French warships *Fleur de Lys*, *l’Abenaquise*, *Tonnant*, *l’Inflexible* and *Dauphin Royal*  
113 translated from French describe conditions in Louisbourg Harbour (McLennan, 1918). Wind  
114 directions from gimballed ships’ compasses reference magnetic north. Bearings and wind  
115 directions used the 32 points of the compass (Smyth, 1867, Blake and Lawrence, 1999) and were  
116 translated to azimuths. The logs of British ships at sea and French ships moored in Louisbourg  
117 Harbour contained: (1) dates and times, (2) position, (3) bearing, (4) wind direction, (5) wind  
118 speed terms that evolved into the Beaufort Wind Scale (e.g., Garcia-Herrera et al., 2005a, 2005b,  
119 Wheeler, 2005, Wheeler et al., 2010), and (6) descriptions of sea state.

120 *2.2 Proxy Climate Context*

121 Major atmospheric circulation patterns that influence Atlantic tropical cyclone behaviour,  
122 specifically the El Nino Southern Oscillation (ENSO) and North Atlantic Oscillation (NAO),  
123 have been reconstructed for the historical period (e.g., Gurgis and Fowler, 2009, Trouet, et al.,  
124 2012). These proxy climate patterns provide an overarching context since La Nina years create  
125 conditions conducive to driving hurricanes in the Atlantic, and a negative NAO allows Atlantic  
126 tropical cyclones to enter the Atlantic and potentially reaching the midlatitude eastern seaboard.  
127 Atmospheric circulation patterns for 1757 were studied to assess overarching conditions  
128 conducive to Atlantic hurricane generation.

### 129 *2.3 Wind Speed*

130 Wheeler and Wilkinson's (2004) analysis of the derivation of the Beaufort scale shows  
131 terms that vary little from the logbook terms used in this study. A similar approach has been  
132 adopted here with adjectives describing primary nomenclature. A 'gale' (Beaufort Force 8) was  
133 originally between a breeze (Force 2) and a violent storm (Force 11) and established a  
134 benchmark (Table 1). A 'near gale,' its diminutive (Smyth, 1867) corresponds to a 'moderate  
135 gale.' Wheeler et al. (2010) categorized 'strong gale,' 'hard gale,' 'blew hard' and 'storm' as  
136 stronger than 'fresh gale.' Adjectives 'stiff' and 'fresh' indicate winds stronger than a gale  
137 (Force 9) while a 'severe' or 'hard' gale reflects a 'storm' (Force 10). 'Excessive' and 'extreme'  
138 hard gale, necessarily stronger than a 'hard gale' would then correspond to 'violent storm' (Force  
139 11) which does not appear in the logs used here. 'Hurricane' (Force 12) is mentioned in both  
140 French and British records. 'Squall' is a historical term for an increase in wind speed sustained  
141 above threshold for at least one minute. The National Oceans and Atmospheric Administration  
142 (NOAA) defines it as a sudden increase by at least 16 knots (33 kph) and sustained at over 22  
143 knots (41 kph) for one minute. Environment and Climate Change Canada (ECCC) defines

<b>Logbook Term</b>	<b>Beaufort Scale</b>	<b>Rating</b>	<b>Wind (kph)</b>
<b>Hurricane</b>	<b>Hurricane</b>	<b>12</b>	<b>118+</b>
<b>Excessive / Extreme Hard Gale</b>	<b>Violent storm</b>	<b>11</b>	<b>103-117</b>
<b>Severe / Hard Gale</b>	<b>Storm</b>	<b>10</b>	<b>89-102</b>
<b>Strong / Stiff Gale</b>	<b>Strong Gale</b>	<b>9</b>	<b>75-88</b>
<b>Gale</b>	<b>Gale</b>	<b>8</b>	<b>62-74</b>
<b>Moderate Gale</b>	<b>Near Gale</b>	<b>7</b>	<b>50-61</b>
<b>Strong / Stiff Breeze</b>	<b>Strong Breeze</b>	<b>6</b>	<b>39-49</b>

144 **Table 1.** Logbook Beaufort Terms and Associated Windspeeds (kph).

145 squalls as increases of 34 knots (63 kph) or more above prevailing winds sustained for over a  
146 minute. The World Meteorological Organization (WMO) uses 8 m/s and 11 m/s (29 and 40 kph)  
147 above threshold for over one minute while the American Meteorological Association (AMA)  
148 notes squalls are of ‘several minutes’ duration. In considering these definitions ‘squall’ is taken  
149 to be a sudden increase in wind speed of 40-60 kph above threshold and sustained for at least one  
150 minute. We interpret ‘hard’ squalls as the upper end of the spectrum in the way adjectives were  
151 used to create the historic Beaufort scale (Wheeler and Wilkinson, 2004). Heavy rains  
152 accompanying squalls noted in the logs appear to be consistent with descriptions of hurricane  
153 spiral bands.

154 In this study the Beaufort Wind Force Scale is used to describe wind speeds from gale to  
155 hurricane force (63-118 kph). The Saffir-Simpson Hurricane Wind Scale describes hurricane  
156 winds greater than 118 kph with peak wind speeds averaged over one minute defining hurricane  
157 intensity Categories 1-5. A major hurricane is Category 3 (178-208 kph) or stronger. Wind  
158 speeds derived from log entries were plotted from the first southeasterlies noted off Nova Scotia  
159 on September 22, 1757, to diminishing westerlies at the storm’s end on September 26.

160 Ephemeral squalls of 1 min duration above threshold winds provide an estimate of total wind

161 speed sustained for one minute or longer. Wind speeds at mid-mast height above the deck plus  
162 freeboard (distance from the waterline to the upper deck) approximate the 10 m height above  
163 ground level for modern hurricane wind speed measurements.

164         Eighteenth century navies knew hurricanes commonly encountered in the Caribbean  
165 sometimes reached North America's eastern seaboard. The modern Saffir-Simpson scale  
166 provides a 1 to 5 storm intensity rating based on a hurricane's maximum sustained wind speed  
167 averaged over one minute. Since no such real time wind force measurement existed in 1757, this  
168 study has adopted Virost et al.'s (2016) engineering analysis of critical hurricane wind speeds that  
169 break trees as a model for estimating threshold wind speeds needed to break ships' masts. Ships'  
170 logs indicate they maintained course relative to prevailing storm winds. This placed vessels at a  
171 highly oblique angle to wave crests which minimized pitch and yaw, and held masts within a  
172 stable plane of reference against which wind applied a sustained force. In addition, large vessels  
173 (74-gun third rates) with up to nine feet of flooding in the hold would have a lower center of  
174 mass that would have affected its righting moment and minimized directional variance in the  
175 wind force striking the masts. Rigging designed to stabilize the masts and transfer wind energy  
176 through the sails would likely have required a higher sustained wind force to achieve failure.

#### 177 *2.4 Wind Direction*

178         Wind direction was measured using the ship's magnetic compass and entered in the  
179 ships' logs as 'points of the compass.' These entries were translated to azimuths. Compass  
180 directions are relative to magnetic north and not corrected for declination given the small study  
181 area and short time frame. Eighteenth century navigation was inaccurate but this study benefits  
182 from (1) log entries of the fleet relying on smaller vessels sent inshore to establish distance from  
183 coastal landmarks, and (2) during the storm ships were driven sufficiently close to land that their

184 positioning entries were based on triangulation using landmarks which greatly improves  
185 accuracy. Experienced navigators were also able to correct for ship motion in their readings  
186 while the ship's position was typically determined by a Lieutenant plus one or more midshipmen  
187 and the sailing master's mate.

### 188 *2.5 Wave Height*

189 Wave height was estimated based on descriptions compared to ship dimensions and is the  
190 last accurate metric. Historic references to ship structure in Imperial Units have been converted  
191 to metric. This includes the distance from the keel to the upper deck and freeboard from the  
192 waterline to the upper deck. The depth of water needed to spill over the bow to flood the upper  
193 deck and tear away large ship's boats tethered to the deck is estimated. References such as  
194 sailors being swept off spars 80' (24 m) above the waterline offers an estimate of peak wave  
195 heights. Warships were designed for stability as floating gun platforms and to return to an 'even  
196 keel' as quickly as possible after firing. Wave descriptions in Louisbourg Harbour are the least  
197 reliable since they include storm surge.

### 198 *2.6 Surge*

199 Surge is a rise in sea level due to atmospheric pressure and storm winds and is  
200 proportional to a tropical cyclone's intensity and translation rate. Coastal surge is a reasonable  
201 estimate of storm intensity and can serve as a test of intensity derived from wind data. The surge  
202 height of modern analogs that struck Nova Scotia after tracking across the Scotian Shelf and  
203 whose intensity has been characterized with metrics derived using modern meteorological  
204 methods provides a reliable benchmark for comparison to surge calculated for the 1757 storm. In  
205 this study, storm surge at known locations and elevations above sea level were described at (1)  
206 Battery de la Grave at Fortress Louisbourg, (2) the historic town within the Fortress, and (3) St.

207 Esprit where the British warship *HMS Tilbury* was stranded in water depths it could not normally  
208 navigate given its displacement. All surge calculations were then corrected for (1) relative sea  
209 level (RSL) rise since 1757, and (2) a mid-tide RSL datum used by Google Earth versus a lowest  
210 low water (tide) datum used by the Canadian Hydrographic Service for a (draft) navigation chart  
211 used for the Tilbury wreck site. In addition, French records noting the tidal change at  
212 Louisbourg allowed for the timing of the tidal cycle to be backed out to determine storm surge  
213 versus storm tide.

214 *Tilbury's* wreck site offered a chance to estimate surge at a second location 45 km  
215 southwest of Louisbourg. *Tilbury's* identity was confirmed in 1986 with the discovery of the  
216 ship's bell, most of its guns, anchors and artifacts (Storm, 2002). Its location remained  
217 undisclosed after a letter from the British High Commission in 2006 reminded the Minister of  
218 Foreign Affairs Canada of the wreck's sovereign immunity, resulting in Nova Scotia rescinding  
219 the associated treasure trove license. Relocating the wreck to confirm its water depth required  
220 creating a digital bathymetric chart needed to guide a marine magnetometer survey leading to  
221 site confirmation by divers.

### 222 **3.0 Little Ice Age Storminess**

223 Matthes (1939) named the LIA to explain European glacier expansion during a  
224 historically colder climate period. Heightened climate variability saw deeply cold winters and  
225 cooler mean annual temperatures primarily in the northern hemisphere (e.g., Kreutz et al., 1997,  
226 Mann, 2002, Jones and Mann, 2004). It may have been triggered by late 13th Century volcanic  
227 eruptions and a cooling feedback process sustained by Arctic sea-ice expansion (Miller et al.,  
228 2012). North Atlantic mean annual SSTs were 1-2°C cooler than today (e.g., Keigwin, 1996,  
229 Winter et al., 2000, Richey et al., 2009, Saenger et al., 2009, Cronin et al., 2010, Bertler et al.,

230 2011, Mazzarella and Scaffeta, 2018, Gebbie, 2019). The Maunder Minimum, the coldest part of  
231 the LIA, (MM; 1645-1715) saw greater ‘storminess’ during polar air breakouts from Europe  
232 correlating to more frequent easterly gales in the English Channel and Approaches in 1685-1750  
233 (Wheeler et al. 2010). Concentrated storm horizons in coastal dunes across western Europe and  
234 in Brittany and on France’s Mediterranean coast correlate to the coldest part of the LIA  
235 (Dezileau et al., 2011, Van Vliet-Lanoe et al., 2014, Sicre et al., 2016, Jackson et al. 2019).  
236 Dezileau et al. (2011) attributed LIA storminess to cold-enhanced lower tropospheric  
237 baroclinicity modifying prevailing westerlies. In the northwest Atlantic, Donnelly et al. (2015)  
238 described major hurricane deposits in New England coastal sediments dating to 1635, 1638 and  
239 1815. Ludlum’s (1963) compilation of historical northwest Atlantic hurricanes and tropical  
240 storms includes the LIA’s major ‘Independence Hurricane’ that struck New England on August  
241 29, 1775 and the ‘Newfoundland Hurricane’ of September 9, 1775, a storm that left 4000 dead to  
242 become Canada’s deadliest hurricane (Ludlum, 1963, Ruffman, 1996). Lamb’s (1991)  
243 exhaustive survey of British and European storms includes the Great Storm that devastated the  
244 British Isles on November 26, 1703. It was an extratropical cyclone equal to a Category 2  
245 hurricane yet Wheeler (2003) notes a far more powerful Atlantic storm on December 1-12, 1792,  
246 also late in Atlantic hurricane season. Both were anomalous for a colder climate period.

247         The Scotian Shelf on Canada’s Atlantic seaboard (Fig. 1) is dominated by the cold, south-  
248 flowing, low-salinity Labrador Current. It originates in the Davis Strait of the Canadian Arctic  
249 and hugs the coast to the start of the midlatitudes at Cape Hatteras, North Carolina where it  
250 meets, mixes with, and redirects seaward the tropical, north-flowing more saline Gulf Stream.  
251 The Labrador Current plays a critical role in hurricane extratropical transition by providing a  
252 coastal buffer of cooler sea surface temperatures that effectively cut off the tropical energy of the

253 Gulf Stream (Hart and Evans, 2001). Summer and fall bring warm water eddies from the Gulf  
254 Stream and warmer coastal SST. Sediment cores from the Emerald Basin off Nova Scotia show  
255 1600 years of cold Labrador Current temperatures and a sudden and sustained warming around  
256 1850 that has continued into the present (Keigwin et al., 2003) and coincides with the end of the  
257 LIA. Storm compilations by Landsea et al. (2004) and Chenowith (2006) show a progressive  
258 increase in the number of historical Atlantic tropical cyclones from 1700 and a sharp increase in  
259 the number and percentage reaching New England and eastern Canada beginning around 1850.  
260 Vecchi and Knutson (2008) in a study of data from the start of instrumental data collection in  
261 1880 show a strong correlation between mean annual SST and storm frequency.

262         Historical records offer seasonal weather detail not captured by annual to multidecadal  
263 proxy trends. Anomalous midlatitude coastal sea surface temperatures (SSTs) over days to  
264 weeks, conditions that fuel tropical cyclones, are therefore not likely to appear in annualized data  
265 weighted by colder, sustained LIA winters. Jacoby and D'Arrigo's (1989) North American  
266 northern and Arctic temperature reconstruction shows above normal temperatures in the 1750's.  
267 Lieutenant John Knox recorded unusually high temperatures in Halifax Harbour on July 20,  
268 1757, which fellow officers found hotter than Gibraltar and the Mediterranean (Knox, 1769).  
269 This coincided with a heat wave in Britain and southwest Europe from July into early August  
270 1757 that set temperature records that stood for over 250 years (The London Chronicle, July 23-  
271 26, 1757; London Magazine, November 1758 p. 563-4). London on July 16-26 had an average  
272 high of 41.2C (Nature Notes, 24 August 1882, p. 415). This does not assume weather conditions  
273 in Europe fueled a hurricane tracking into Atlantic Canada, but demonstrates that unusually hot  
274 temperatures across the northern hemisphere known to intensify midlatitude hurricanes existed in  
275 the summer of 1757.

276           The 1757 hurricane noted by Poey (1855) and Ludlum (1963) was confirmed as a  
277 hurricane in Chenowith's (2006) re-assessment compilation. It was first seen off Florida and  
278 followed the coastline past Cape Hatteras to New England on September 22-24 (Ludlum, 1963).  
279 Benjamin Franklin's observations of this specific storm led him to conclude that hurricanes "are  
280 produced by currents of cold winds rushing from the north along the Atlantic coast and mingling  
281 with the warm winds produced by the gulf-stream" (Warden, 1819). It struck the British frigate  
282 HMS Winchelsea on September 23 to 24 at 36°45'N 70° 54'W (off North Carolina over the Gulf  
283 Stream). The log notes gale force east then east-southeast and south winds between 10 p.m. and  
284 5 a.m. on September 23 which, 15 minutes later, veered violently to the northeast and then  
285 northwest at 'near hurricane' intensity. It split the main sail and broke the main mast. It was also  
286 accompanied by a 'great sea' (ADM 52/1105).

287           The storm passed New England on September 24 (Boston Herald, Oct. 17, 1757, Ludlum  
288 1963) and struck Nova Scotia as the Louisbourg Storm on September 25, 1757. Its arrival at Fort  
289 Cumberland on the Nova Scotia border 200 km inland late September 22 included 'violent rain'  
290 and 'constant heavy rain' into the 23rd. Knox's journal on the 27th describes September 24-26  
291 with ... 'I never saw such storms of wind and rain as we have had for some days past...'  
292 followed by 'windy, showery and very cold' weather on the 27-28th and 'dry, cold windy  
293 weather' on the 29th, followed by frost and snow across Nova Scotia by mid-October (Knox  
294 1769).

#### 295 **4.0 Historical Context**

296           The Seven Years' War (1756-1763) arose from unresolved issues following the Treaty  
297 of Aix-la-Chappelle that ended the War of the Austian Succession (1740-1748). It began as a  
298 European conflict between Great Britain and allies and France and its allies, but soon extended to

309 the colonial interests of both nations in North America and India. It resulted in significant losses  
300 for France including the loss of New France, now Canada, to Great Britain (Syrett, 2008).  
301 Britain's overwhelming success in gaining territory at France's expense during the war led  
302 France to subsequently support the secession of the American colonies in 1775.

303 Great Britain's 'Grand Plan' for the North American campaign began with John  
304 Campbell, the 4th Earl of Loudoun, being appointed Commander-in-Chief of the British military  
305 in North America. His adversary was Louis-Joseph de Montcalm-Grozon, Marquis de Montcalm  
306 de Saint-Veran, commander of French forces in North America. To attack Montcalm at Quebec  
307 without leaving a powerful French fortress at his rear, Loudoun needed to first seize Fortress  
308 Louisbourg in Nova Scotia. On May 22 to 25, 1757, troops boarded 134 transport ships in New  
309 York to rendezvous at Halifax with a fleet departing Britain under Vice Admiral Frances  
310 Holbourne. Pitt's brief removal as Prime Minister delayed the fleet but his return to power with a  
311 coalition government saw it depart Cork, Ireland, on May 8, 1757. The delay allowed France to  
312 reinforce Louisbourg with three naval squadrons ahead of the British arrival. On May 23 five  
313 French battleships and a frigate under Chevalier Joseph de Beaufremont arrived from the West  
314 Indies, followed on June 15 by four battleships and two frigates under Joseph Francois de Noble  
315 du Revest from Toulon. On June 20 nine battleships and two frigates under Vice Admiral  
316 Emmanuel-Auguste de Cahideuc (Comte Dubois de la Motte) arrived from Brest. 4000 French  
317 troops bolstered a garrison of 3200 plus 300 Acadians and Mi'kmaq warriors (McLennan, 1918,  
318 Stoetzel, 2008). Holbourne's arrival at Halifax on June 30 bolstered Loudoun's force to create an  
319 army of 12 000. *HMS Gosport* arrived on August 5 with letters intercepted from a French  
320 schooner captured off Newfoundland detailing Louisbourg's reinforcement. It rendered the

321 attack on the fortress untenable. Loudoun returned to New York and on September 11, 1757  
 322 Holbourne sailed his fleet north to blockade Louisbourg (Fig 1).

323 **5.0 The Louisbourg Storm**

324 The British fleet cruised off the coast of Cape Breton Nova Scotia (Fig. 1) to lure the  
 325 French fleet out of Louisbourg Harbour to do battle. On September 21, the British 80-gun  
 326 flagship *Newark* noted fresh westerly gales followed by fair weather and light breezes then calm  
 327 with fog on the 22nd. That day an officer on the French 28-gun frigate *Fleur de Lys* saw a low  
 328 mist enter Louisbourg Harbour. The mist was also seen at sea by the British *Invincible* until it  
 329 dissipated under a rising southeast breeze. Britain’s *Newark* and France’s *Fleur de Lys* recorded  
 330 that the breeze veered to the southeast and intensified to moderate gales on September 22. The  
 331 *Invincible* recorded strengthening easterlies September 22-26 from otherwise prevailing  
 332 westerlies through the second half of September (Table 2).

333  
 334 **Table 2.** Prevailing Winds (HMS *Invincible* Logbook)

335 Prevailing wind direction measured for each of three successive 8-hour watches per day and  
336 azimuth equivalent on the *Invincible*. Storm winds, arriving September 22, 1757, off Cape  
337 Breton, are shaded and in italics; two watches with easterlies not associated with the storm are  
338 shaded only. Mean 250.5 (WSW) prevailing wind direction six days before and five days  
339 following storm (continued westerly on 28 and 29). Mean 135 (SE) wind direction during storm.  
340 Ships off St. Esprit on September 25 saw prevailing southeasterly winds last until September 26.  
341 Ships south of St. Esprit including *Invincible*, *Sunderland* and *Windsor* faced southwesterly  
342 winds on September 25.

343 French naval officers, expecting a storm due to the southeast winds, moored the French  
344 fleet in two lines off Royal Battery (Fig. 2) with four 2-ton anchors at the bow of each ship. The  
345 southeast winds led the British ships at sea to secure masts and naval guns, weighing as much as  
346 3 tons apiece, anticipating a storm. On the 24th *Invincible* and *Newark* reported increasing cloud,  
347 haze and rain beginning under southeast gales.

348

349 **Figure 2.** Louisbourg Harbour showing the French fleet anchorage, Louisbourg Lighthouse,  
350 Royal Battery, Battery de la Grave Guardhouse, and the southeast seawall overlain on chart  
351 image © Canadian Hydrographic Service (2011) Chart Guyon Island to Flint Island 1:37,866  
352 [Issued 2022-11-26]. Shoals (shaded) relative to ship hull displacements of 5.8-7.0 m (19 to 23')  
353 give a general sense of the scale of waves and surge needed to throw battleships on shore and  
354 destroy the southeast facing seawall.

355 On September 25 fresh southeast gales rose to excessive hard gales with very heavy rain.  
356 The British *Windsor* noted heavy rain and mist and intensifying strong gales with hard squalls.  
357 At 7 p.m. *Sunderland* faced very hard gales that rose to extreme hard gales by 10 p.m. At 12  
358 a.m. *Invincible* faced strong gales, torrential rains and a 'great sea.' At 2 a.m. on the 25th  
359 *Invincible* noted an 'excessive hard gale' and 'a hurricane of wind' and mountainous waves.  
360 Topsails used to control ships in severe weather were 'blown to rags.' *Sunderland's* main  
361 staysail was torn away. Waves 'made a free passage over...' the 70-gun *Devonshire* and  
362 smashed in *Lightning's* stern. The wind tore away the 8-gun *Cruiser* sloop's mizzen mast and  
363 three sailors were swept overboard. *Cruiser* was 'very near foundering having been underwater  
364 several times' and jettisoned its guns to stay afloat.

365 *Windsor's* log records extreme gales with severe squalls, heavy rain and a great sea.  
366 Canvas tarpaulins stripped off deck gratings by the wind allowed waves and rain to flood the  
367 ships which soon had up to 2.5 m (9') of water in the holds despite the pumps in full operation.  
368 *Windsor* and *Sunderland* sailed S across SSW winds. *Grafton's* three-ton 7 m (30') rudder was  
369 torn off the ship. *Invincible's* rudder, also torn free, was only saved by its preventer chains.  
370 Sails on all the British ships at sea were torn away by the wind. Captain Bently later reported  
371 that *Invincible's* hull planking had opened and broke iron reinforcing brackets and bolts,

372 allowing the entire gun deck and its tens of tons of heavy naval guns to drop several inches  
373 (Captain's Letters, ADM 1/1488). *Sunderland's* foretopmast, reinforced by ten 5 cm (2") rope  
374 shrouds plus stays, was torn off the ship and it disappeared into the night with two sailors.  
375 *Invincible* was thrown onto her 'beam ends' (side), forcing it to heave overboard ten 12-pounder  
376 upper deck guns and carriages, roughly twenty tons, to right the ship. *Invincible's* main yard was  
377 ordered taken down but before it could be done the wind broke off the 38" (1 m) diameter  
378 mainmast 20' (6 m) above the deck. The falling mast tore down the foretopmast and mizzen mast  
379 and crushed the starboard gunwale. The wreckage pulled the ship onto its side and swept sailors  
380 John Guttredge and Samuel Kirby into the sea. *Invincible's* sailors cut the tangled mass free  
381 before it sank the ship.

382           At Louisbourg, the French military officer at La Grave Battery (Fig. 2) led his troops to  
383 safety after the sea rose steadily above their knees (Chevalier de Johnstone, 1758). Offshore, the  
384 British 14-gun *Ferret* sloop under Francis Upton and a crew of 104 was lost with all hands.  
385 Around 6 a.m. *Invincible* noted five British ships dangerously close to shore. *Eagle* was blown  
386 onto its beam ends and jettisoned ten upper deck guns and cut down its mizzen mast to right the  
387 ship. *Captain's* foretopmast was torn away and took its two topmen. *Lightning* found it was  
388 drifting toward offshore breakers less than 200 m away. Captain Faulkner ordered *Windsor's*  
389 guns jettisoned. He noted *Invincible* had lost all but its lower foremast and bowsprit. *Sunderland*  
390 was swept by 'a very heavy large sea' that 'passed freely over us.' Barges lashed to the decks of  
391 *Windsor* and *Invincible* were smashed and swept overboard. *Sunderland* cut down its main  
392 topmast and threw guns overboard to right the ship. The wind snapped its 61 cm (24") diameter  
393 mizzen mast as it drifted toward the offshore breakers. Anchors did not slow its drift so the  
394 mainmast was cut down. *Sunderland* stopped close to the breakers and less than a kilometer from

395 shore. The 74-gun *Terrible* also stopped its drift almost at the breakers. *Eagle's* foretopmast was  
396 cut down to lessen the strain on the ship. It sailed southward narrowly missing the breakers.  
397 *Newark* regained control after cutting the anchor cable and heaving guns overboard and barely  
398 cleared the line of breakers. Dawn revealed a signal flag had been raised by the French fishing  
399 village of St. Esprit to give the crews of the British ships hope (Knox Bristol Journal, November  
400 12, 1757).

401 At Louisbourg the French fleet was pummeled by severe winds and waves. The 70-gun  
402 French battleship *Dauphin Royale* fired a gun in distress when its anchor cables snapped under  
403 the strain. *Dauphin Royale* collided with the 80-gun *Tonnant*, destroying its bowsprit, figurehead  
404 and cutwater, and damaged *Tonnant's* rudder and poop deck. The two ships crossed  
405 *l'Abenaquise's* anchor cables and the three entangled ships were heaved on shore at Royal  
406 Battery (Fig. 2) along with 25 merchant ships, 50 schooners and 80 small vessels, many high and  
407 dry and with many sailors drowned (McLennan, 1918).

408 At sea, by 10 a.m. the British fleet was dangerously close to the breakers off St. Esprit.  
409 Many sailors were certain they were doomed (Knox Bristol Journal, November 12, 1757).  
410 *Grafton* struck a rock but floated free and managed to set an anchor. *Windsor* and *Eagle* had  
411 been able to sail south of the main British fleet off St. Esprit. *Eagle's* Captain Palliser saw what  
412 he judged to be *Nottingham* or *Tilbury* near shore, within the breakers, its bow facing shore with  
413 its fore and mizzen masts gone. He also recorded that it was afloat and attempting to wear (turn)  
414 but lost sight of it in heavy rain.

415 Waves tore down sections of the French Fortress Louisbourg's massive southeast facing  
416 stone seawalls. Locals brought news of lakes 10 km inland being reached by the sea. Seawater  
417 rose to flood the streets of the Town of Louisbourg, 'something never before seen' (Chevalier de

418 Johnstone, 1758). Eventually the beached French battleship *Tonnant* ‘floated with the tide’ as  
419 the wind veered south and then west at 11 a.m.

420           At sea the British warship *Windsor* noted the wind turned to blow from the west at 11:30  
421 a.m. but had strengthened. *Eagle* recorded that the squalls had lessened by noon. On the  
422 *Sunderland* massive waves swept sailor George Lancey from the fore yard 24 m (80’) above the  
423 keel. By 3 p.m. waves at Louisbourg fell enough that *l’Inflexible* was able to send sailors to assist  
424 other ships. French captains petitioned 74-year-old Admiral Dubois de la Motte to attack the  
425 stricken British ships off their coast but his orders to defend Louisbourg had been met and he  
426 kept his ships in port. James Johnstone, a Scot serving as a French officer, felt that five French  
427 warships if they had ventured to sea could have captured the entire British fleet (Chevalier de  
428 Johnstone, 1758). This sentiment was subsequently shared by Lady Anson, daughter of a  
429 confidante of Lord Newcastle with whom Pitt had formed his coalition government, in an  
430 October 31, 1757 letter to the First Lord of the Admiralty, her husband George Anson (Anson,  
431 1757). On September 27th a boat arrived at Louisbourg from St. Esprit with news that the British  
432 warship *Tilbury* had wrecked there with over 120 lost. Four schooners with 160 French troops

434 **Table 3.** Timeline of Louisbourg Storm (September 25)

435 Timeline of storm impacts on the British fleet at sea increasingly scattered by the storm and the

436 French fleet moored in Louisbourg Harbour. Relative ship locations, south to north, are blue,

437 orange, green and grey. British ships were relatively static (drifting, sailing under reefed sails or

438 at anchor) but *Invincible* sailed across storm winds to end up south of *Windsor* and *Sunderland*.

439 It is not known when *Ferret* sank but it had been sent ahead of the fleet prior to the storm to  
440 undertake reconnaissance of the French fleet at Louisbourg.  
441 were unable to counter the heavy seas so they marched to the site across land flooded by the  
442 torrential rain. Mi'kmaq warriors gained the wreck first but informed the shipwrecked British  
443 they would not be harmed since the storm had brought them to their lands (Moreau St. Mery *in*  
444 McLennan, 1918).

## 445 **6.0 Deriving Storm Metrics**

446 Storm intensity is reflected in key metrics including wind speed and direction, wave  
447 height and surge which is driven by a rise in sea level due to atmospheric pressure and sustained  
448 storm winds and is proportional to a cyclone's intensity, translation rate and the bathymetric  
449 gradient of the continental shelf.

### 450 *6.1 Estimating Storm Wind Speed*

451 The wind speed required to cause structural failure in masts was estimated. Virot et al.  
452 (2016) determined the critical wind force needed to break trees of average integrity is 151 kph  
453 irrespective of species with a +9% factor for large diameter trees. 165 kph assumes structural  
454 defects due to longer tree life offset the structural advantage of size, yet masts were chosen for  
455 their lack of defects. Fir and pine trees of superior structural integrity were selectively harvested  
456 for Royal Navy masts into the 1770's from North America, Great Britain and the Baltic (Lavery,  
457 1984). Masts were also not free-standing (like trees) but reinforced by rigging to effectively  
458 transfer wind energy from the sails to the hull. *Invincible's* masts were secured by sixteen 5 cm  
459 (2") hemp shrouds per side, each tensioned with paired deadeye blocks, the lower block in an  
460 iron band bolted to the ship's frame. Its 1 m (38") diameter lower mainmast stepped against the  
461 ship's keelson rose 35.7 m (117') through two decks. Above it stood a 21.3 m (70') 51 cm (20")

462 diameter topmast and above that the 10.7 m (35') 28 cm (11") diameter topgallant mast (Lavery,  
463 1984, 1988). To achieve the critical wind speed of 165 kph, taken as a minimum due to the  
464 factors noted, *Invincible's* motion must be considered.

465 *Invincible* sailed SW under SE winds, but gradually encountered SW winds. *Sunderland*  
466 and *Windsor* sailed south across SSW winds while most ships of the British fleet to their north  
467 near St. Esprit faced SSE winds. *Invincible* was among the southernmost ships (Fig. 1). It sailed  
468 SW½W (230°) against EbS (101°) winds on September 24. During the storm its displacement  
469 was 98 km toward 256.7° (22.5 km S; 96 km W). 6 km SE (135°) of Chedabucto Bay it faced W  
470 (270°) winds and SE surface currents estimated at 3.49 kph based on currents of 0.97 m/s based  
471 on currents there during SE winds from Hurricane Juan in 2003 (CBCL Report, 2015).

472 On September 25 to 26 *Invincible* sailed 159 km toward 102.75 degrees. The ship spent  
473 11 hours under SE winds and another 11 hours under SW winds. The last 2 hours it drifted west  
474 under jury rig. The strongest winds were SW (225°). Cosine Law (Figure 4) gives a wind speed  
475 of 170.62 kph to achieve 165 kph at the mast on the moving vessel. The 5.62 kph difference  
476 infers vessel motion played only a minor role in reaching critical force yet is still 18% of the  
477 Saffir-Simpson Category 3 wind force range. Ephemeral squalls of 40-60 kph added to sustained  
478 winds of 170.62 kph suggests peak winds might have reached 211-231 kph. Admittedly an  
479 imperfect solution, it assumes a minimum critical force. It does not consider the inherently  
480 superior structural integrity of masts plus their reinforcement by rigging, suggesting major  
481 hurricane threshold winds (178 kph) could have been met even without considering squalls.

482

483 **Figure 3.** Hurricane wind evolution with time. The time sequence shows the arrival of southeast  
 484 winds (Beaufort Scale) intensifying to hurricane winds (118 kph), peaking to sustained 171 kph  
 485 *see Fig. 4)* critical wind force with increasing squalls, followed by a rapid decline to gale force  
 486 westerlies. The horizontal axis is divided into days (noon) and 2-hour intervals. The vertical  
 487 scale is wind speed in kph. A best fit curve [1] is typical of windspeeds as a hurricane passes a  
 488 fixed point. A best fit curve for squall frequency [2] in ships' logs adds ephemeral wind speed to  
 489 sustained winds. 171 kph is considered the minimum critical wind force considering the superior  
 490 materials integrity of masts and their reinforcement with rigging. Peak winds lasted 9 hours  
 491 while hurricane force winds impacting the fleet lasted 15 hours. Wind directions represent, north  
 492 to south, winds affecting: French ships at Louisbourg, British ships near St. Esprit, *Windsor* and  
 493 *Sunderland* south of St. Esprit, and *Invincible* closest to the eye (Fig 1). Southernmost (blue)  
 494 through southern (orange), off St. Esprit (green) and Louisbourg (grey) show the general

495 distribution of ship logs (see Table 3). *Invincible* sailed past *Windsor* and *Sunderland* during the  
 496 storm and into the SW winds they had encountered earlier.

Using Cosine Law, we solve for velocity a where  $\alpha$  is 122.25 degrees:

$$a^2 = b^2 + c^2 - 2bc \cos \alpha$$

$$a^2 = (165)^2 + (10.13)^2 - 2 \times (165 \times 10.13) \times \cos (122.25)$$

$$a^2 = 27,225 + 102.62 - 2 \times (1671.45) \times (-0.5336)$$

$$a^2 = 27,327.62 + 1783.77$$

$$a = 170.62 \text{ kph from } 227.75 \text{ degrees (where } b = 165 \text{ kph and } \beta = 55 \text{ degrees)}$$

497  
 498 **Figure 4.** Correction for Vessel Motion. *Invincible* drifted 159 km toward 102.75° between  
 499 September 25 and 26 over 24 hours. It experienced SE (11 hours), then SW (11 hours) and  
 500 finally W winds (2 hours). This solution focuses on the 11 hours the ship was under SW winds,  
 501 the strongest winds closer to the center of the cyclone (Fig. 3). During elapsed hours 59-70 the  
 502 vessel sailed toward 102.75 under a SW wind (225°) at an average of 6.64 kph based on the total  
 503 displacement of 159 km toward 102.75°. The incident angle between the wind and the ship  
 504 displacement vectors is 122.25°. A surface current in Chedabucto Bay during SE winds from  
 505 Hurricane Juan (CBCL Report, 1995) of 0.97 m/s (3.492 kph) is assumed to be a reasonable  
 506 estimate for this study. The resultant of 6.64 kph toward 102.75° indicates speed relative to  
 507 surface currents was 10.13 kph. Image not to scale.

508 Anticlockwise wind vectors at ship locations are tangential to concentric cyclonic wind bands.  
509 Normal lines drawn to these vectors converge to identify the location of the eye. Interestingly  
510 they lack the asymmetry diagnostic extratropical cyclone wind fields (Fig. 7). This process,  
511 repeated to plot the eye location on September 26, 1757, indicates the storm crossed Cape Breton  
512 and entered the Gulf of St. Lawrence. Even if the wind field began to collapse, the location of the  
513 storm center suggests the system may have slowed while passing over Cape Breton Island.

## 514 *6.2 Estimating Storm Wave Height*

515 *Sunderland's* and *Devonshire's* upper decks were submerged after waves broke over the  
516 forecastle. The 12.2 m (40') distance from the keel to the upper deck plus an estimated 3-6 m  
517 (15-20') to break over the forecastle and tear away ship's boats lashed to the deck requires a  
518 wave height of about 18 m (60') (Lavery 1983). *Lightning's* stern gallery 40-50' above the keel  
519 was destroyed by waves striking the ship from astern, also requiring waves of about 12.2 m  
520 (60'). A sailor swept out of *Sunderland's* fore yard by a wave necessitates a wave of about 25-30  
521 m (80-90'). While carrying considerable uncertainty, these examples provide estimates of  
522 significant and maximum wave heights. Waves sufficiently large to tear down stone seawall  
523 rampart of Fortress Louisbourg are consistent with these estimates, as are waves capable of  
524 reaching inland lakes. Descriptions of the sea state in Louisbourg Harbour by French naval  
525 officers resulting in extensive damage to ships and boats suggests waves much larger than any  
526 recorded in modern times even though wave energy from the southeast would have been partly  
527 attenuated by shoals (Fig. 2).

528 On September 26-28, 1818, the American frigate *USS Macedonian* met a hurricane off  
529 Bermuda (35°N 53°W) and suffered damage nearly identical to *HMS Invincible* in 1757 from  
530 waves of 12 m (40') (Saegesser 1970). The dates appear to coincide with Chenowith's (2006)

531 'Final Storm Number 253' listed as a hurricane in Table IV. Damage to the ship closely parallels  
532 that described for the 1757 hurricane except that line of battle ships had a much heavier  
533 construction than a frigate. Saegesser (1970) provides a very detailed account based on the ship's  
534 log and ancillary damage reports, and notes that in the same storm the Dutch brig De Hoope lost  
535 all topmasts and spars, the brig Ann from Nova Scotia was abandoned at sea, the brig Mary from  
536 Bristol was overturned, the ship Catherine Dawes from Philadelphia sank and a Baltimore  
537 schooner and a Nantucket whaler were both dismasted. *Invincible's* substantially more robust  
538 build than the frigate *Macedonian* implies larger, more powerful waves caused its damage.

### 539 6.3 Estimating Surge Height

#### 540 6.3.1 Surge at Louisbourg Harbour

541 A Parks Canada coastal erosion study at Fortress Louisbourg National Historic Site  
542 revealed iron mooring rings set in the remains of a seawall. Modern high tide compared to these  
543 rings established historical high tide 0.90 m (3') of sea level rise since 1757 (Duggan, 2010). La  
544 Grave Battery (Fig. 2) is 2.0 m (6.6') above sea level (asl; Google Earth mid-tide datum), so sea  
545 level rise plus flooding to sentries' knees (0.5 m) yields a 3.4 m (11') mid-storm surge. Historic  
546 buildings along the waterfront (Fig. 2; 45°53'33.57" N 59°59'07.89" W) are 5 m (16.4') asl  
547 while the first street, Rue Royale, is 7 m (22.9') asl. Seawater flooding the town streets at the  
548 lowest levels and adjusted for sea level rise indicates 5.9 m (19.4') to 7.9 m (21.4') of surge.  
549 *Tonnant* 'floated with the tide' when the wind veered south at 11 a.m. on September 26 (*Fleur de*  
550 *Lys* log in McLennan, 1918). Louisbourg's 12-hour tidal cycle and assuming low tide around 10  
551 a.m. gives a high tide at 4 a.m. coinciding with storm landfall and creating a storm tide (Fig. 3).  
552 Backing out the 1.5 m (5') tidal range gives a 4.4-6.4 m (14.4-21') peak surge, consistent with  
553 the earlier surge of 3.4 m (11') at La Grave.

554 6.3.2 Surge at St. Esprit (Tilbury Wreck)

555 *HMS Tilbury* was a 58-gun square-rigged warship lost on the coast in the storm. *Eagle's*  
556 captain saw either *Tilbury* or *Nottingham* shoreward of the breakers near St. Esprit, 45 km south  
557 of Louisbourg. It was deduced to have been *Tilbury* since *Nottingham* survived the storm with a  
558 different array of masts than seen on this ship. 'Wreck' appears on a 1776 chart (Fig. 5). Storm  
559 (2002) used Zinck's (1975) image of an 18th Century 6-pounder British naval gun at 'Tilbury  
560 Rocks' to view *Tilbury's* wreckage in 4 m (15') from a boat in 1969.

561  
562 **Figure 5.** Excerpt from a historic chart of Cape Breton Island showing the general St. Esprit  
563 study area and *HMS Tilbury* wreck site, from Mowat (1776), depicted in Figs. 6a,b. The faint  
564 dotted line right of Barnsley Lake, named for *Tilbury's* captain, marks a parish boundary.

565           The historic navigation chart (Fig. 5) showed parish boundaries marked by fieldstone  
566 walls of historic St. Esprit (Fig. 6a, b) which helped identify the line of offshore breakers  
567 described in British naval logs. A draft hydrographic chart (Hanson, 1954) was digitized and  
568 gridded with missing data interpolated. Paired depths and locations were entered in a spreadsheet  
569 and a grid-plot of local bathymetry supported a marine proton magnetometer survey of Tilbury  
570 Reef isobaths following best practices for submerged archaeological sites (Cornwall Council  
571 Report 2010-R012). Dipole targets investigated by divers led to locating a mid-18th Century 6-  
572 pounder British naval gun *in situ* in 3 m (10') which was 2.1 m (7') in 1757, near the site of the  
573 6-pounder on shore, both interpreted to be from *Tilbury's* forecastle. In 1757 *Tilbury* was  
574 observed at the time as 'bow in' near shore, landward of the breakers and 'attempting to wear'  
575 (turn). It was in water sufficiently deep for its 18' displacement as it was, at the time, afloat and  
576 under sail. Adding in the hydrographic survey datum offset of 0.6 m (2') between lowest low tide  
577 at St. Esprit and the Google Earth WGS84 (World Geodetic Standard 1984) mid-tide datum for  
578 Louisbourg suggests a minimum 4.0 m (13') surge at St. Esprit. Post-storm relaxation flow  
579 stranded the *Tilbury* (Fig. 6b) allowing native warriors to reach it.

580

581

582 **Figure 6a.** Location of Tilbury shipwreck. Inset map X – X' ( $45^{\circ}38'31.21''$  N  $60^{\circ}27'41.99''$  W  
583 to  $45^{\circ}38'31.61''$  N  $60^{\circ}26'05.28''$  W) corresponds to Fig. 6b. Dashed line is bedrock reef  
584 (breakers). Image © Google Earth Pro 7.3.6.9345 (2022) St. Esprit, Nova Scotia Canada.

587

588 **Figure 6b.** Bathymetry of *Tilbury* wreck site at lowest low water adjusted for 1757 relative sea  
 589 level (solid line) and minimum surge (dashed line) needed to float *Tilbury*. Coastal retreat of 27  
 590 m (90') calculated from historic sea level gives the 1757 shoreline. Topographic and bathymetric  
 591 data were kept in Imperial units for comparison to *Tilbury's* displacement. X and X' of this block  
 592 diagram correspond to the same GPS positions on the areal chart in Fig. 6a.

593

594 **Figure 7. Eye location and estimated translation speed.** Plots of wind vectors on September  
 595 25 at: (1) Invincible, (2) Windsor and Sunderland, (3) Newark and most of the British fleet,  
 596 French ships at Louisbourg Harbour. Normal lines taken to wind vectors cluster at the eye.  
 597 Estimated translation rates are based on the storm off North Carolina, New England and  
 598 Chedabucto Bay on the dates shown, showing increased translation typical of midlatitude  
 599 cyclones, yet a similar wind vector reconstruction for September 26 gives an eye location  
 600 entering the Gulf of St. Lawrence, suggesting the system slowed over Cape Breton after landfall.

601 **7.0 Modern Analogs**

602 On September 29, 2003, Hurricane Juan struck Nova Scotia with peak winds of 165 kph  
 603 (Category 2), a significant wave height of 10 m (32'), a maximum wave height of 19.9 m (65')  
 604 and a surge at landfall near Halifax of 1.5 m (4.9') (Lixion, 2003). On January 20-22, 2000, an  
 605 extratropical meteorological 'superbomb' that developed off Cape Hatteras struck Nova Scotia  
 606 with peak winds of 25-30 m/s (90-108 kph), a significant wave height of 12 m (39'), a peak wave

607 height of 19 m (62') to 23 m (77') at drilling rigs near Sable Island (JD pers. obs.) and a 1.4 m  
608 (4.6') surge at landfall near St. Esprit (Lalbeharry et al., 2009). Both cyclones produced similar  
609 sea states and surge which can be compared to the Louisbourg Storm. On September 24, 2022,  
610 Category 3 Hurricane Fiona began extratropical transition as it crossed the Scotian shelf. A cold  
611 trough over Nova Scotia directed its landfall to the Canso Peninsula. Winds of 140 kph in Nova  
612 Scotia reached 177 kph in Newfoundland and Labrador. Significant and maximum wave heights  
613 were 17 m (56') and 30 m (98') and surge reached 2.4 m (8').

614 In 1969 Category 5 Hurricane Camille generated a 7.3 m (24') storm tide from 1.8-3.0 m  
615 (6-10') surge (U.S. Department of Commerce Environmental Science Services Administration  
616 1969) while Category 5 Katrina in 2005 produced a storm tide of 8.2 m (27') (Knabb et al.,  
617 2023). Hurricane Laura (Category 4) in 2020 had a peak 5.2 m (17.2') surge (Pasch et al., 2021)  
618 and a 2.7-4.0 m (9-13') spanning 130 km from Beaumont to Lake Arthur, Texas. In 2018  
619 Hurricane Dorian (Cat 5) slowed to 2 kph over the Bahamas creating an 8.5 m (28') surge (Avila  
620 et al., 2020). Surge from these major hurricanes cannot be readily compared to storm strikes in  
621 Nova Scotia due to different coastal bathymetry but they allow a general comparative  
622 benchmark.

623 Hurricane Juan's translation speed before landfall was 1-5 m/s (4-18 kph). Compared to  
624 North Atlantic hurricane translation rates of 17.7-19.3 kph (11-12 mph) the Louisbourg Storm  
625 slowing from 31 kph over water to 4.6 kph after landfall between September 25-26 may have  
626 enhanced surge height, similar to Dorian's impact on the Bahamas as it slowed, resulting in the  
627 exceptional surge height at Louisbourg. Prevailing westerlies returned after the storm. The key  
628 metrics of wind speed, wave height and surge are summarized in Table 4.

Storm	Year	Date	Peak Wind (kph)	Significant Wave Height (m)	Peak Wave Height (m)	Surge (m)
Louisbourg	1757	25-Sep	171 - 231	12+	25-30	4.4 – 6.4
Unnamed	2000	22-Jan	90 - 108	12	19	1.4
Juan	2003	27-Sep	160 - 165	10	20	1.5
Fiona	2022	24-Sep	155 - 179	17	30	2.4

629

630 **Table 4. Louisbourg Storm Comparison to Modern Nova Scotia Landfalling Storms.** The  
631 Louisbourg Storm, a winter extratropical storm in 2000, Juan (Category 2 hurricane at landfall),  
632 and Fiona, an extratropical cyclone that transitioned from a Category 3 hurricane over the  
633 Scotian Shelf crossed the same coastal bathymetry with similar translation rates to strike Nova  
634 Scotia. Sustained winds for the Louisbourg Storm exceeded 171 kph based on the critical force  
635 needed to break main and mizzen masts and break away and carry off topmasts and may have  
636 reached 231 kph with squalls. Peak wind is presented as the range between sustained threshold  
637 and maximum wind speeds.

638 **8.0 Discussion**

639 Metrics derived from historical data captured during the Louisbourg Storm of 1757  
640 indicate its intensity surpassed any modern (post-1851) Atlantic cyclones striking the same  
641 region. Historical records show the Louisbourg Storm originated in the tropics to pass Florida,  
642 the Carolinas and New England to strike Nova Scotia on September 25, 1757. It developed at  
643 the height of hurricane season under an optimal NAO index and ENSO conditions for Atlantic  
644 hurricanes to form and track up the Atlantic coast of North America into the northern  
645 midlatitudes. The already low NAO index also decreases later in the season and may have helped  
646 stay over the Gulf Stream which allowed it to intensify into higher latitudes. Its devastating  
647 impact on the British and French fleets and coastal infrastructure was due to an unusually violent

648 release of energy over coastal waters. Longer, colder LIA winters skewed mean average  
649 temperature profiles but a UK and European heat wave in Europe in 1757, extreme even by  
650 modern standards, shows seasonal temperature variability could contribute to warmer SSTs and  
651 fuel tropical cyclones in the LIA. A strong correlation between SST and tropical cyclone  
652 frequency (Vecchi and Knutson, 2008) suggests that the LIA's cooler SSTs could see fewer  
653 storms per year. Mean-annual temperature data limited by temporal resolution limitations likely  
654 mask peak temperatures that likely existed over smaller areas for shorter periods but historical  
655 records clearly show tropical cyclones developed even during the coldest part of the LIA.

656         The large number of British warships scattered along Cape Breton's coast by the  
657 Louisbourg Storm provided a spatial resolution of wind vectors not normally available in storm  
658 reconstructions. It was partly facilitated by ships sailing across storm winds to avoid being  
659 driven ashore. The proximity of many British ships to shore and the severe surge and wave  
660 action at Louisbourg led many contemporary naval authorities of both nations to fear the  
661 catastrophic loss of the British and French fleets and 20 000 sailors. Only the reversal of wind  
662 direction at the last minute as the eye of the storm passed prevented a disaster.

663         Wind speed is the key metric used in the Saffir Simpson scale to characterize the intensity  
664 of modern cyclones. Engineering models are a standard method of determining the force  
665 required to trigger structural failure in materials. Trees lacking defects that negate size advantage  
666 were preferentially selected for masts and so likely required higher wind speeds for structural  
667 failure. Rigging not only reinforced masts but redirected wind energy to the hull. Both factors  
668 imply that the wind speed estimate of 171 kph determined for *Invincible* to achieve 165 kph at  
669 the mast is an underestimate. Sustained winds likely exceeded the 178 kph (Cat 3) major  
670 hurricane threshold even without considering squalls of 40-60 kph. Extreme winds are reflected

671 in topmasts (along with shrouds and stays) not only being torn off two British ships but being  
672 carried off (with sailors) instead of falling to the deck. British ship positions were triangulated  
673 against known coastal landmarks which provided greater accuracy in the distribution of wind  
674 vectors. Superimposing *Invincible's* location and the wind vectors that identify the eye location at  
675 the height of the storm suggests severe damage was a consequence of proximity to the eye which  
676 is the location of a cyclone's strongest winds (Figs. 1,3, 7). Peak damage and squalls above  
677 hurricane winds lasted 9 hours and hurricane force winds noted by the British ships lasted 15  
678 hours as the center of the storm passed the coast (Fig. 3). In comparison, Hurricane Juan crossed  
679 Nova Scotia in only 3 hours while Fiona crossed the province in under 6 hours, supporting the  
680 interpretation derived from eye locations (Fig. 7) that the Louisbourg Storm slowed over land,  
681 possibly due to a blocking cold air high. The British warship Tilbury was driven into water  
682 depths at St. Esprit it could navigate only under a storm tide. Tidal reversal mid storm stranded  
683 the ship near shore (Figs. 3, 6a,b).

684 Wind plots also show that the southernmost ships of the British fleet faced southwest  
685 winds from the lower right quadrant of the hurricane. British ships to the northeast near St. Esprit  
686 faced southeast winds. The French fleet in Louisbourg Harbour also faced southeast winds and  
687 an anomalously high storm surge which allowed massive waves to drive ships on shore while the  
688 surrounding region was flooded by torrential rains, all consistent with the front right quadrant of  
689 the hurricane where the most severe impacts are felt. There was no suggestion that the air of the  
690 storm was cold, but westerlies following the storm were described at Fort Cumberland as very  
691 cold and dry. A table of wind directions for the second half of September 1757 (Table 2) shows  
692 that, with the exception of the storm, prevailing winds appear to have been continental  
693 westerlies.

694 Modern analogs show strong similarities in significant and maximum wave height, but  
695 interpreted wind speeds for the Louisbourg storm are greater than those of Category 2 hurricane  
696 Juan, a winter extratropical ‘superbomb’ in 2000, and the extratropical cyclone Fiona in 2022.  
697 Surge measured at three locations is consistent with the scale of surge from major hurricanes in  
698 the Gulf of Mexico and Caribbean. The 1757 surge greatly exceeds that of modern analogs that  
699 crossed the same bathymetry with similar translation speeds. This consistent basis of comparison  
700 of surge height, closely linked to storm intensity, shows the Louisbourg Storm had an intensity  
701 far beyond a Category 2 system and was equal to a major hurricane. Surge calculated  
702 independently for the lowest streets of the historic town of Louisbourg, Battery de la Grave and  
703 the *Tilbury* wreck at St. Esprit were also consistent. Unlike the modern analogs, storm surge at  
704 Louisbourg reflects conditions one hundred kms from landfall (Fig. 7).

705 The climatology of tropical cyclones on North America’s eastern seaboard renders the  
706 simple attribution of ‘tropical’ vs. ‘extratropical’ problematic. It is unlikely that a fully tropical  
707 system with wind speeds equal to a Category 4 hurricane to strike Nova Scotia. Atlantic tropical  
708 cyclone extratropical transition is triggered by the interaction of autumn continental westerlies  
709 pushing strongly baroclinic air eastward toward intensifying tropical cyclones tracking north into  
710 the higher midlatitudes of the North American eastern seaboard when SSTs peak in late  
711 September into October. This is consistent with climatic drivers interpreted by Dezileau et al.  
712 (2011) and Jackson et al. (2019) to explain historic European LIA storminess. Storm intensity  
713 normally drops following extratropical transition, but not always (Hart and Evans, 2001). The  
714 National Hurricane Center (NHC) uses sea surface temperatures plus storm asymmetry in  
715 satellite images to indicate the degree of transition. Hart and Evans (2001) also found that ‘the  
716 NHC declaration (of extratropical transition) typically occurs early in the 1 to 2-day period ...

717 when the storm is just beginning to lose its tropical characteristics.’ This is not easy to assess for  
718 the Louisbourg Storm whose energy release may have occurred over a short period. The lack of  
719 eye asymmetry of the storm at landfall on September 25 based on the convergence of normal  
720 lines to vectors at ship locations (Fig. 7) suggests it may have had largely tropical characteristics  
721 at landfall. It leads to questioning at what point was it ‘tropical’ (hurricane) vs. ‘extratropical’  
722 given the NHC’s 1 to 2-day range? It was likely both in the coastal zone. The storm’s large size  
723 is indicated by its winds first being recorded on September 22 by both the British and French  
724 fleets at Cape Breton on the same day it struck the British frigate *Winchelsea* off North Carolina,  
725 1350 km to the southwest. This may have enabled it to continue to draw tropical energy from the  
726 Gulf Stream as it neared the Nova Scotia coastline. Hart and Evans’s (2001) extratropical  
727 climatology based on an analysis of all Atlantic tropical cyclones over a century. It shows that  
728 systems can continue to see tropical intensification north of strongly baroclinic conditions that  
729 trigger transition, resulting in an explosive release of energy and post-transition intensification.  
730 Their analysis shows this typically involves hurricanes from south of 20 N that retained an  
731 intensely tropical character into the higher midlatitudes. In fact, their analysis of past Atlantic  
732 hurricanes shows that the region most conducive to this process in the entire North Atlantic basin  
733 lies immediately south of Cape Breton, Nova Scotia, where the Louisbourg Storm was in 1757.

## 734 **9.0 Conclusions**

735 In 1757 continental westerlies, colder and earlier than today in the LIA, juxtaposed a cold  
736 higher pressure air mass against a large, intensifying hurricane approaching Cape Breton. The  
737 resulting explosive release of energy gave the Louisbourg Storm its highly destructive power. Its  
738 unusual intensity required only an incremental change in the accepted climatology of Atlantic  
739 cyclone extratropical transition, that being the early arrival of colder LIA continental westerlies

740 driving a steeper temperature gradient. The storm slowed over Nova Scotia as it encountered a  
741 blocking high, indicated by the short distance between eye locations on September 25 and 26, as  
742 well as by the duration of hurricane force winds (15 hours) over the coast, which may have been  
743 enhanced by the storm's large diameter. The slowing storm drove an unusually high surge at high  
744 tide. Tidal reversal stranded the *Tilbury* close to the historical shoreline. Fall westerlies arriving  
745 earlier in the LIA would have expanded southward sooner and allowed an intensifying hurricane  
746 to enter a zone more baroclinically favourable for transition. In the future, instead of an earlier  
747 arrival of colder continental westerlies in fall, a warming North Atlantic could drive tropical  
748 intensification in to higher latitudes later into the autumn to trigger increasingly destructive  
749 storms over coastlines that have seen a meter of sea level rise and extensive coastal growth since  
750 the Louisbourg Storm nearly rewrote history two and a half centuries ago. It is a reminder that  
751 the past can inform the present, and the future.

## 752 **Acknowledgements**

753 The authors would like to thank William Pretel and Antoine LaChance for constructive review  
754 comments on the manuscript. Research assistance was provided by Cambria Huff (Dalhousie),  
755 John Allison (UK), the National Archives (UK) and the Public Archives of Nova Scotia. Tony  
756 Sampson, commercial diver, offshore survival instructor and owner/operator of Salty Dog Sea  
757 Tours, and Steve Jennex, Dave Murphy, Steve Dugas and Dana Sheppard of Zodiac Divers  
758 coordinated marine operations and underwater exploration.

## 759 **Funding**

760 The authors declare that no funds, grants, or other supports were received during the preparation  
761 of this manuscript and that they have no financial or proprietary interests in any material  
762 discussed in this article.
