Article Title: Polar Mesospheric Summer Echo (PMSE) Multilayer Properties During Solar Maximum and Solar Minimum
Authors: D. Jozwicki et al.

Referee Report

The article deals with the characteristics of PMSE layers, focussing on multi-layers during periods of enhanced and lower solar activity. It is clearly and concisely structured. In the introduction, a comprehensive literature review is given, providing relevant background information on the topic. Section 2 explains the methods of data selection and analysis in an easily understandable way. The results obtained are presented and discussed in detail in section 3 and then summarised in section 4.

After reviewing the paper for the second time, I can say that the authors have adequately taken into account the recommendations and suggested corrections that I made in the first review. In its current form, the manuscript has become much easier to read and has provided new information on the subject under investigation. I therefore consider the manuscript suitable for publication in its present form.
