14 Abstract

13

Red beds belong to slippery formations, and their rapid identification is of great significance for 15 major scientific and engineering issues such as geological hazard risk assessment and rapid response. 16 17 Existing research often identifies red beds from a qualitative or semi quantitative perspective, resulting in slow recognition speed and inaccurate recognition results, making it difficult to quickly handle 18 landslide geological disasters. Combined with the correlation between red beds geomorphic 19 characteristics, mineral compositions, and chemical compositions, this study established a preliminary 20 identification quantitative criterion based on the basic chemical composition combination rules 21 (SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub>, Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>, FeO+Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>/FeO, K<sub>2</sub>O+Na<sub>2</sub>O, Na<sub>2</sub>O/K<sub>2</sub>O, CaO+MgO, and MgO/CaO) 22 in the red beds. Then, perform principal component analysis on the basic chemical composition 23 24 combination rules mentioned above. The results indicate that simultaneously meeting the following 25 principal component features can serve as a rapid quantitative criterion for distinguishing red beds from other rocks:  $F1=-3.36\sim23.55$ ,  $F2=-23.00\sim3.11$ ,  $F3=-10.12\sim4.88$ ,  $F4=-2.21\sim4.52$ ,  $F5=-0.97\sim7.30$ , and 26  $F = -0.67 \sim 1.89$ . By comparing the chemical composition combinations of 15 kinds of rocks collected 27 from China in this study, it is proven that the quantitative criterion proposed in this study are effective. 28

- The study results can be used for rapid identification of red beds, achieving risk assessment and rapid response of geological disasters such as landslides.
- 31 **Keywords:** red beds, quantitative criterion, geological disasters, rapid response, chemical compositions

## 1. Introduction

Red beds are widely distributed throughout the world (Zhou et al., 2023b; Yan et al., 2019; Chen et al., 2021). Geological disasters occur frequently in the red beds distribution area, especially landslides, debris flows, collapses, and underground engineering damage (Chen et al., 2014; Zhou et al., 2023a; Wang et al., 2022b). According to the characteristics of disasters such as landslides, the red beds belong to "landslide prone strata", and the instability of slopes with weak interlayers of the red beds is particularly evident (Zhang et al., 2015). This is mainly due to the strong hydrophilicity and weak permeability of the red beds, which are prone to softening and plastic deformation under the action of water; After absorbing water, the red beds are easy to expand, and after losing water, they are easy to contract; The weathering resistance of the red beds are weak, they are easy to collapse, and their compressive and shear strength are low (Zhang et al., 2016; Wu et al., 2018; Wang et al., 2017; Marat et al., 2022; Zhang et al., 2024). The red beds have different lithology or poor binding force with other rock strata, which can easily cause differential deformation and lead to rock mass sliding along the bedding plane (Liu et al., 2020; He et al., 2023; Wang et al., 2024). Therefore, the identification of rock types, especially the rapid determination of red beds, is of great significance for major scientific and engineering issues such as risk assessment and rapid response of geological disasters in red beds distribution area. At present, the studies on red beds identification are mostly carried out from the perspectives of geomorphic characteristics, mineral compositions, and chemical compositions (Cui et al., 2022; Zhou et al., 2021). And, there is a close relationship between these perspectives (Moonjun et al., 2017; Bankole et al., 2016; Perri et al., 2013). For example, the content of Fe<sub>2</sub>O<sub>3</sub> or hematite in the red beds is higher than that in the grey beds (Hu et al., 2006). Among these perspectives, the research of geomorphic characteristics and mineral compositions mostly adopts qualitative or semi quantitative methods, and there are many such studies. For example, Rainoldi et al. (2015) identified red beds by

studying the color of geomorphic characteristics and hematite in mineral compositions, and studied the mechanism of red beds bleaching. Uchida et al. (2000) distinguished red sandstone, yellowish brown sandstone, and green sandstone according to the content of hematite, goethite, biotite, and muscovite in the mineral compositions, analyzed the characteristics of different rocks and pointedly protected Angkor monuments. Xue et al. (2023) distinguished red mudstone and red sandstone by quantifying the clay mineral content in the mineral compositions, in order to analyze the mechanisms and control factors of summer uplift of high-speed railway cutting. At this stage, the research on the geomorphology, mineral color and clay content of the red beds lays the foundation for the identification of the red beds, but this identification is still vague and needs to be further quantified. Therefore, some scholars have conducted quantitative studies on the chemical compositions of red beds. Hong et al. (2009) analyzed the alteration of clay minerals by studying the changes in the SiO<sub>2</sub>/Al<sub>2</sub>O<sub>3</sub> ratio in the chemical compositions of the red beds, thereby obtaining the weathering degree of the red beds. Bankole et al. (2016) studied the relationship between Fe/Mg ratio, Fe<sup>3+</sup>/FeT ratio, and Cr/Fe ratio of red beds to indirectly study the oxygen content of the Paleoproterozoic. Hu et al. (2006) studied the characteristics of high Fe<sub>2</sub>O<sub>3</sub> content and low FeO content in the oceanic red beds, and analyzed ancient landslides on the continental margin from the perspective of petrology. However, these studies do not distinguish between red beds and other rocks in terms of chemical compositions. The use of portable spectrometers and drone-borne multi-sensor remote sensing technique can quickly obtain the chemical compositions of rocks in geological disasters while ensuring safety (Triantafyllou et al., 2021; Kirsch et al., 2018), making it feasible to use chemical compositions as the standards to distinguish red beds from other rocks.

Therefore, the purpose of this study to develop a quantitative criterion for quickly and accurately identifying the red beds. This study first collected the data about the geomorphic characteristics, mineral content, and chemical composition of red beds and other rocks, then compared these data to obtain the basic characteristics of red beds, and finally summarized and analyzed the red beds identification criterion and verified the reliability of this criterion.

# 2. Methods

Figure 1 shows the methodology used in this study involving the investigation of geomorphic characteristics, mineral compositions, and chemical compositions (the perspective of chemical compositions is the focus of this study). In this study, data on geomorphological features, mineral content and chemical composition of the red beds and other rocks were first collected, then these data were compared to derive the basic characteristics of the red beds, and finally the red bed identification criteria were summarized and analyzed, and the reliability of the criteria was verified.

**Figure 1.** Methodology for identifying red beds from geomorphic characteristics, mineral compositions, and chemical compositions.

## 2.1 Data collection

The geomorphic characteristics data were collected from the previous studies about landslides, debris flows, and collapses on of red beds, igneous rocks (andesite, basalt, diorite, granite),

metamorphic rocks (gneiss, marble), and other sedimentary rocks (arkose, black-shale, breccia, claystone, dolomite, lignite, limestone, marl, mudstone, siliciclastic, tuff) (e.g., (Zhang et al., 2015; San et al., 2020; He et al., 2021; Ciftci et al., 2008; Perez-Rey et al., 2019; Anbarasu et al., 2010; Xia et al., 2019; Gokbulak and Ozcan, 2008; Li et al., 2016; Wang et al., 2022a; Zhang et al., 2017; Underwood et al., 2016; Kavvadas et al., 2020; Harp et al., 2011; De Montety et al., 2007; Contino et al., 2017; Liu et al., 2018; Ni et al., 2015; Hale et al., 2021)). The geomorphic characteristics of red beds investigated in this study involve the evolution process and distribution of red beds on Earth's surface, and the results were compared with that of other types of rock samples.

The mineral compositions of red beds (1,536 groups data) were collected from the previous studies as shown in Supplementary Table 1 (e.g., (Jian et al., 2009; Liu et al., 2020; Zha et al., 2022; Bai et al., 2020; Zhang et al., 2021; Zhang et al., 2020; Yao et al., 2016; Li et al., 2023; Marat et al., 2022; Wang et al., 2017; Chen et al., 2014; Zhang et al., 2016; Li et al., 2015; Li et al., 2013; Wang et al., 2018; Wang et al., 2014)). These studies used semi quantitative or quantitative methods in XRD technology to statistically analyze the differences in mineral composition between different red beds (*e.g.*, quartz, feldspar, mica, hematite, clay minerals, and calcite), as detailed in the aforementioned literatures. This study mainly focuses on the influence of mineral compositions on geomorphic characteristics, particularly the layered structure and color of red beds.

The chemical compositions of red beds (1536 groups data) with different geological ages and various lithologies such as conglomerate, sandy conglomerate, sandstone, siltstone, shale and mudstone were collected from the previous studies as shown in Supplementary Table 2 (e.g., (Uchida et al., 2000; Xue et al., 2023; Jiang et al., 2022; Yang et al., 2016; Liu et al., 2020; Kong et al., 2018; Zhao et al., 2005; Gao et al., 2017; Zhang et al., 2008; Liu et al., 2006; Zhu et al., 2003; Liu et al., 2007; Hong et al., 2009; Wild et al., 2017)). The chemical compositions of igneous rocks, including andesite (Supplementary Table 3 - 49,203 groups data. Data were downloaded from the GEOROC database (https://georoc.mpch-mainz.gwdg.de//georoc/) on 11 May 2023, using the following parameters: search = andesite), basalt (Supplementary Table 4 - 80,365 groups data. Data were downloaded from the GEOROC database on 11 May 2023, using the following parameters: search = basalt), diorite (Supplementary Table 5 - 4,941 groups data. Data were downloaded from the GEOROC database on

126 11 May 2023, using the following parameters: search = diorite), and granite (Supplementary Table 6 -127 17,272 groups data. Data were downloaded from the GEOROC database on 11 May 2023, using the 128 following parameters: search = granite). The chemical compositions of metamorphic rocks, including 129 gneiss (Supplementary Table 7 - 24,300 groups data. The data were downloaded from the EarthChem 130 Portal Database (http://portal.earthchem.org/) on 20 April, 2018, using the following parameters: 131 material = metamorphic and rock name = gneiss) and marble (Supplementary Table 8 - 3,364 groups data. The data were downloaded from the EarthChem Portal Database on 12 May, 2023, using the 132 133 following parameters: material = metamorphic and rock name = marble). The chemical compositions 134 of other sedimentary rocks, including arkose (Supplementary Table 9 - 682 groups data. The data were downloaded from the EarthChem Portal Database on 10 May, 2023, using the following parameters: 135 material = sedimentary and rock name = arkose), black-shale (Supplementary Table 10 - 305 groups 136 data. The data were downloaded from the EarthChem Portal Database on 10 May, 2023, using the 137 following parameters: material = sedimentary and rock name = black-shale), breccia (Supplementary 138 Table 11 - 1,396 groups data. The data were downloaded from the EarthChem Portal Database on 10 139 May, 2023, using the following parameters: material = sedimentary and rock name = breccia), claystone 140 (Supplementary Table 12 - 3,790 groups data. The data were downloaded from the EarthChem Portal 141 142 Database on 10 May, 2023, using the following parameters: material = sedimentary and rock name = claystone), dolomite (Supplementary Table 13 - 2,169 groups data. The data were downloaded from the 143 144 EarthChem Portal Database on 6 May, 2023, using the following parameters: material = sedimentary and rock name = dolomite), lignite (Supplementary Table 14 - 3 groups data. The data were downloaded 145 from the EarthChem Portal Database on 24 April, 2018, using the following parameters: material = 146 sedimentary and rock name = lignite), limestone (Supplementary Table 15 - 9,104 groups data. The 147 148 data were downloaded from the EarthChem Portal Database on 10 May, 2023, using the following 149 parameters: material = sedimentary and rock name = limestone), marl (Supplementary Table 16 - 142 150 groups data. The data were downloaded from the EarthChem Portal Database on 10 May, 2023, using 151 the following parameters: material = sedimentary and rock name = marlstone, marl), mudstone 152 (Supplementary Table 17 - 6,140 groups data. The data were downloaded from the EarthChem Portal Database on 10 May, 2023, using the following parameters: material = sedimentary and rock name = 153

mudstone, mud), siliciclastic (Supplementary Table 18 - 26,938 groups data. The data were downloaded from the EarthChem Portal Database on 10 May, 2023, using the following parameters: material = sedimentary and rock name = siliciclastic), tuff (Supplementary Table 19 - 10,295 groups data. The data were downloaded from the EarthChem Portal Database on 6 May, 2023, using the following parameters: material = sedimentary and rock name = tuff).

Studies have found that rock disasters are related to the content of minerals such as quartz, clay minerals, hematite, calcite, dolomite, feldspar, etc., and these mineral contents are also closely related to the combination of major elements or oxides (Table 1), for example, SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub> (used to study the relative content relationship between quartz and clay minerals) (Hong et al., 2009), Fe<sub>2</sub>O<sub>3</sub> and FeO (used to study the high content characteristics of hematite) (Hu et al., 2006), CaO and MgO (used to study the content relationship of potassium feldspar, calcite, and dolomite) (Han et al., 2023), Na<sub>2</sub>O and K<sub>2</sub>O (Qiao et al., 2017). Therefore, this study on the basic chemical composition combination rules and quantitative criterion of the red beds only involves the major elements mentioned above, and does not involve the analysis of trace elements or other stable isotopes.

**Table 1.** Chemical composition (%) of minerals in red beds from database.

Mineral chemical formulas	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	Fe <sub>2</sub> O <sub>3</sub>	FeO	CaO	MgO	Na <sub>2</sub> O	K <sub>2</sub> O	H <sub>2</sub> O	CO <sub>2</sub>

data.

In order to verify the proposed basic chemical compositions combination rules and quantitative criterion of red beds, 15 kinds of rocks of known rock types were selected in Guangdong, Sichuan, Hubei, Zhejiang, and Anhui provinces (Figure 2), including 12 kinds of red beds (red claystone, red mudstone, red silty mudstone, red argillaceous siltstone, red fine sandstone, red medium sandstone, red coarse sandstone, red conglomerate, etc.), limestone (1 kind), arkose (1 kind) and mudstone (1 kind). After on-site sampling, use a hammer to smash the rock block out of the fresh surface. Then, the fresh surface was analyzed using the YL-P-3LRX Handheld Laser Induced Breakdown Spectroscopy (LIBS, Figure 3) to check whether these elements conform to the basic chemical compositions combination rules of red beds proposed by this study. This device can detect elements such as K, Na, Si, Al, Ca, Mg, Fe, and oxides. The working principle of the LIBS is that a miniature X-ray source provides tube voltage and tube current, and the light tube emits continuous X-ray spectral lines. The X-rays irradiated on the sample knock out the inner electrons of the K and L layers of the element atoms, and the holes in the lowenergy layer are filled by high-energy outer electrons (N layer). The high-energy electrons emit excess energy as X-ray fluorescence ( $K\alpha$ ) with elemental characteristics. Thus, the instrument detects the type and concentration of elements through the emitted spectral lines. On the instrument analysis interface, point the detection window towards the rock sample and press the trigger to start and stop the measurement. After amplification and data collection, the signal is processed to obtain the required test

# 3.1 Geomorphic characteristics of red beds

Geomorphic characteristics of the red beds as shown in Figure 4. Red beds are sedimentary rocks of different geological ages (mainly Mesozoic and Cenozoic) with bedding structure typically consisting of various lithologies such as conglomerate, sandy conglomerate, sandstone, siltstone, shale and mudstone that are predominantly red in color due to the presence of ferric oxides (Yan et al., 2019). Owing to differences in depositional environments and influences of late stage geologic processes, the color of red beds can be brownish-reddish-yellow, brownish-yellow, purplish-red, brownish-red, grayish-purple and other reddish tints (Yan et al., 2019; Nance, 2015), making it difficult to accurately describe using the CIELAB color space and/or Munsell color system. Bedding is a common structural feature of sedimentary rocks representing the changes in the sedimentary environment. The sandstone is one of the most common types of red beds, with a distinct reddish appearance. Compared with the obvious layering and red appearance characteristics of red beds, igneous rocks and metamorphic rocks do not show the two characteristics of red appearance and bedding at the same time. Basalts are reddish in appearance but does not have bedding (Cunha et al., 2005). In addition, andesites are mainly light black and have a columnar structure which is similar to that of basalts (Feizizadeh et al., 2021). Most of granites are grey or light brown with a significantly different structure compared to red beds (Migon et al., 2018), while gneisses are generally characterized as a dark and light gneissic structure (Garajeh et al., 2022). Although the red color appearance and bedding structure can be used as qualitative criteria for identifying the red beds, the analysis of mineral and chemical compositions is still necessary for identifying the rocks from quantitative perspective.

Red beds Yadan landform

Red beds Danxia landform

**Figure 4.** Geomorphic characteristics of the red beds.

#### 3.2 Mineral compositions of red beds

Table 2 shows the statistical analysis results of mineral compositions of red beds in Supplementary Table 1. The common minerals in the red bed are quartz (median value is 40%, the same below), clay minerals (35%, including kaolinite, illite, montmorillonite, and chlorite), feldspar (10%, including K-feldspar and plagioclase), calcite (10%), mica (7%, including biotite, muscovite and sericite), and hematite (3%) according to their content. According to the average value and standard deviation, it can be seen that the content range of various minerals has significant dispersion. The ratio of the content of clay minerals to other minerals (quartz, feldspar, mica, hematite, and calcite) ranges between 0.11 to 1.50. The hematite content ranges between 1.5% and 10.0% (percentile=10%~90%), and reddish appearance of red beds is due to the abundant hematite content of the rocks. The change in mineral compositions of red beds could lead to the change in rock color which is one of the major characteristics of red beds. Furthermore, when the red beds encounter water, softening and expansion could happen because of the large amount of clay minerals in the rocks, especially the mudstone. The differences in mineral compositions of the red beds can also be quantitatively described through their chemical composition combination characteristics (Table 1).

**Table 2.** The statistical analysis results of mineral compositions of red beds from literature data.

Minerals	Range	Range	Median value	Average	Standard deviation	
Willierais	$(per = 0\% \sim 100\%)$	(per = 10%~90%)	(per = 50%)	value		
Quartz (%)	2.3~94.0	21.0~69.0	40.0	42.6	18.8	
Clay minerals (%)	1.0~80.0	7.8~59.0	35.0	34.1	18.6	
Feldspar (%)	0.4~71.0	2.3~25.0	10.0	12.6	10.7	
Mica (%)	0.1~40.8	3.0~20.0	7.0	9.2	8.2	
Hematite (%)	0.4~25.2	1.5~10.0	3.0	5.0	4.4	
Calcite (%)	0.7~97.7	3.1~23.5	10.0	12.2	10.0	
Clay minerals/	0.01 6.00	0.11, 1.50	0.61	0.76	0.66	
Other minerals	0.01~6.00	0.11~1.50	0.61	0.76	0.66	

Note: per – percentile; Other minerals – quartz, feldspar, mica, hematite, and calcite.

# 3.3 Chemical composition characteristics of red beds

Figures 5~6 are mainly used to qualitatively analyze the differences in chemical compositions between the red beds and other rocks through scatter plots. The area surrounded by black dashed lines

is the area where the red beds data points are located. To better distinguish various rock data points, the distribution areas of various rock data are shown on the right side of the figure, and the corresponding colored dashed ellipses are used to indicate the distribution areas in the dataset. Figure 4 shows the comparison of SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub>, FeO and Fe<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>O and Na<sub>2</sub>O, CaO and MgO contents in red beds, igneous rocks, and metamorphic rocks, respectively. Figure 5 shows the comparison of SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub>, FeO and Fe<sub>2</sub>O<sub>3</sub>, K<sub>2</sub>O and Na<sub>2</sub>O, CaO and MgO contents in red beds and other sedimentary rocks respectively.

271

The content of SiO<sub>2</sub> in the red beds is about 30%~80%, Al<sub>2</sub>O<sub>3</sub> is about 8%~30%, Fe<sub>2</sub>O<sub>3</sub> is about 0%~10%, FeO is about 0%~3%, K<sub>2</sub>O is about 0%~10%, Na<sub>2</sub>O is about 0%~2.5%, CaO is about 0%~10%, and MgO is about 0%~5%. Compared with igneous rocks, metamorphic rocks, and other sedimentary rocks, the content of each chemical composition of the red beds has three relationships with the content of corresponding chemical composition of other rocks: inclusion relationship (the data distribution range of one rock completely covers and is larger than the data range of the other rock), intersection relationship (the data distribution range of one rock intersects with the data distribution range of another rock), and mutual difference relationship (the data distribution range of one rock does not intersect at all with the data distribution range of another rock). The distribution range of SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub> content in the red beds includes the distribution range of SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub> content in 9 types of rocks, namely andesite, basalt, diorite, granite, black shale, claystone, mudstone, siliciclastic, and tuff. The distribution range of SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub> content in the red beds intersects with that in breccia, lignite, and marl. The distribution range of SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub> content in gneiss, marble, arkose, dolomite, and limestone is different from that in the red beds. The distribution range of Fe<sub>2</sub>O<sub>3</sub> and FeO content in the red beds includes the distribution range of Fe<sub>2</sub>O<sub>3</sub> and FeO content in granite, marble, and lignite. The distribution range of Fe<sub>2</sub>O<sub>3</sub> and FeO content in the red beds intersects with that in 8 kinds of rocks, namely, andesite, basalt, diorite, breccia, claystone, dolomite, limestone, and mudstone. The distribution range of Fe<sub>2</sub>O<sub>3</sub> and FeO content in gneiss, arkose, black shale, siliciclastic, and tuff is different from that in the red beds. The distribution range of K<sub>2</sub>O and Na<sub>2</sub>O content in the red beds includes the distribution range of K<sub>2</sub>O and Na<sub>2</sub>O content in lignite. The distribution range of K<sub>2</sub>O and Na<sub>2</sub>O content in the red beds intersects with that in 15 kinds of rocks, including andesite, basalt, diorite,

granite, marble, arkose, black shale, breccia, claystone, dolomite, limestone, marl, mudstone, siliciclastic, and tuff. The distribution range of  $K_2O$  and  $Na_2O$  content in gneiss is different from that in the red beds. The distribution range of CaO and MgO content in the red beds includes the distribution range of CaO and MgO content in granite, black shale, and lignite. The distribution range of CaO and MgO content in the red beds intersects with that in 13 types of rocks, including andesite, basalt, diorite, gneiss, arkose, breccia, claystone, dolomite, limestone, marl, mudstone, siliciclastic, and tuff. The distribution range of CaO and MgO content in marble is different from that in the red beds. Therefore, from a qualitative perspective, it can be seen that the red beds differ in chemical composition from 8 kinds of rocks, including gneiss, marble, arkose, dolomite, limestone, black-shale, siliciclastic, and tuff, and also intersects with other rocks to varying degrees. But this is not enough as a criterion to determine the difference between red beds and other rocks.

**Figure 5.** Comparison of (a) SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub>, (b) FeO and Fe<sub>2</sub>O<sub>3</sub>, (c) K<sub>2</sub>O and Na<sub>2</sub>O, (d) CaO and MgO contents in red beds, igneous rock, and metamorphic rocks, respectively. (Note: Icons of the same color in the figure have the same meanings)

**Figure 6.** Comparison of (a) SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub>, (b) FeO and Fe<sub>2</sub>O<sub>3</sub>, (c) K<sub>2</sub>O and Na<sub>2</sub>O, (d) CaO and MgO contents in red beds and other sedimentary rocks respectively. (Note: Icons of the same color in the figure have the same meanings)

Figures 7~8 mainly analyze the differences in chemical compositions between red beds and other rocks through further data statistics and box plots of the scatter plots mentioned above, and propose quantitative identification criterion for the red beds chemical compositions combination. The red dashed box in the figure represents rocks that differ from the red beds data, while the black dashed box represents rocks that intersect less than 25% with the red beds data. The data collected in section 2.1 comes from published papers or databases, and its accuracy and robustness have been explained in

relevant literature. In order to ensure the exclusion of outliers in the box plots mentioned above during the analysis of this study. The horizontal gray dashes corresponding to the red beds box chart represent 10% percentile (the same below), lower quartile (25% percentile), median (50% percentile), upper quartile (75% percentile), and 90% percentile in the red beds data from bottom to top. Figure 6 shows the chemical compositions combination comparison of SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub> (total content, the same below) and Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> (content ratio, the same below), FeO+Fe<sub>2</sub>O<sub>3</sub> and Fe<sub>2</sub>O<sub>3</sub>/FeO, K<sub>2</sub>O+Na<sub>2</sub>O and Na<sub>2</sub>O/K<sub>2</sub>O, CaO+MgO and MgO/CaO in red beds, igneous rock, and metamorphic rocks, respectively. Figure 7 respectively shows the chemical compositions combination comparison of SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub> and Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>, FeO+Fe<sub>2</sub>O<sub>3</sub> and Fe<sub>2</sub>O<sub>3</sub>/FeO, K<sub>2</sub>O+Na<sub>2</sub>O and Na<sub>2</sub>O/K<sub>2</sub>O, CaO+MgO and MgO/CaO in red beds and other sedimentary rocks. The SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub> content in the red beds is 54.7%~85.0% (10%~90% percentile, the same below), the Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> ratio is 0.14~0.41, the FeO+Fe<sub>2</sub>O<sub>3</sub> content is 0.9%~7.9%, the Fe<sub>2</sub>O<sub>3</sub>/FeO ratio is 1.52~7.70, the K<sub>2</sub>O+Na<sub>2</sub>O content is 1.6%~6.8%, the Na<sub>2</sub>O/K<sub>2</sub>O ratio is 0.02~0.43, the CaO+MgO content is 0.8%~9.2%, and the MgO/CaO ratio is 0.16~1.57. By comparing the content of SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub>, the red beds are distinct or have small intersections (less than 25%, the same below) with granite, marble, dolomite, lignite, limestone, and marl. By comparing the Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub> ratio, it is found that the red beds are distinct or have small intersections with gneiss, marble, arkose, and lignite. By comparing the content of FeO+Fe<sub>2</sub>O<sub>3</sub>, it is found that the red beds are distinct or have small intersections with basalt, gneiss, arkose, and siliciclastic. By comparing the Fe<sub>2</sub>O<sub>3</sub>/FeO ratio, it is found that the red beds are distinct or have small intersections with andesite, basalt, diorite, granite, gneiss, marble, arkose, black shale, dolomite, mudstone, siliclastic, and tuff. Through the comparison of K<sub>2</sub>O+Na<sub>2</sub>O content, the red beds are distinct or have small intersections with granite, marble, breccia, dolomite, and limestone. By comparing the Na<sub>2</sub>O/K<sub>2</sub>O ratio, the red beds are distinct or have small intersections with andesite, basalt, diorite, gneiss, lignite, siliciclastic, and tuff. Through the comparison of CaO+MgO content, the red beds are distinct or have small intersections with andesite, basalt, gneiss, marble, breccia, dolomite, limestone, and marl. By comparing the MgO/CaO ratio, it is difficult to distinguish the red beds from other rocks.

**Figure 7.** Chemical compositions comparison of (a) SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub>, Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>, (b) FeO+Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>/FeO, (c) K<sub>2</sub>O+Na<sub>2</sub>O, Na<sub>2</sub>O/K<sub>2</sub>O, (d) CaO+MgO, MgO/CaO in red beds, igneous rock, and metamorphic rocks.

**Figure 8.** Chemical compositions comparison of (a) SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub>, Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>, (b) FeO+Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>/FeO, (c) K<sub>2</sub>O+Na<sub>2</sub>O, Na<sub>2</sub>O/K<sub>2</sub>O, (d) CaO+MgO, MgO/CaO in red beds and other sedimentary rocks.

In summary, there are differences in chemical compositions between red beds and other rocks. Simultaneously meeting the following chemical compositions combinations as a preliminary quantitative criterion to distinguish red beds with different geological ages and various lithologies from other rocks:  $SiO_2+AI_2O_3\approx 50.7\%\sim85.0\%$ ,  $AI_2O_3/SiO_2\approx 0.14\sim0.41$ ,  $FeO+Fe_2O_3\approx 0.9\%\sim7.9\%$ ,  $Fe_2O_3/FeO\approx 1.52\sim7.70$ ,  $K_2O+Na_2O\approx 1.6\%\sim6.8\%$ ,  $Na_2O/K_2O\approx 0.02\sim0.43$ ,  $CaO+MgO\approx 0.8\%\sim9.2\%$ , and  $MgO/CaO\approx 0.39\sim1.08$ .

# 3.4 Principal component analysis and quantitative criterion for red beds identification

Based on the preliminary quantitative criterion for identifying the red beds mentioned above, this section presents PCA statistical analysis (dimensionality reduction) of the SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub>, Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>, FeO+Fe<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>/FeO, K<sub>2</sub>O+Na<sub>2</sub>O, Na<sub>2</sub>O/K<sub>2</sub>O, CaO+MgO, and MgO/CaO of red beds in Figures 7 and 8. The result is significant with P<0.05 (Table 3), rejecting the null hypothesis. There is correlation between the variables, and principal component analysis is effective. It can be seen that the cumulative variance interpretation rate of the first five principal components reaches 94.788% (generally greater than 90% is sufficient), indicating that using the first five principal components can be well used for red beds recognition.

Table 3. Variance explanation

Components	Characteristic roots	Variance interpretation	Cumulative variance interpretation rate (%)			
		rate (%)				
1	2.700	33.754	33.754			
2	2.249	28.112	61.866			
3	1.169	14.613	76.479			
4	0.882	11.023	87.503			
5	0.583	7.285	94.788			
6	0.263	3.293	98.081			
7	0.131	1.638	99.72			
8	0.022	0.280	100.00			

According to the component matrix (Table 4) obtained during the PCA analysis process, the calculation equations for 5 principal components  $F1\sim F5$  (Equations 1-5) and the calculation formula for the overall principal components F (Equation 6) can be obtained.

# Table 4. Principal component matrix

Chemical composition combinations	Principal component 1	Principal component 2	Principal component 3	Principal component 4	Principal component 5
SiO <sub>2</sub> +Al <sub>2</sub> O <sub>3</sub>	0.274	-0.281	-0.115	-0.014	-0.009
Al <sub>2</sub> O <sub>3</sub> /SiO <sub>2</sub>	0.085	0.356	0.283	-0.199	-0.352
FeO+Fe <sub>2</sub> O <sub>3</sub>	-0.103	0.334	-0.071	0.449	0.702
Fe <sub>2</sub> O <sub>3</sub> /FeO	0.194	0.038	0.268	0.827	-0.449
K <sub>2</sub> O+Na <sub>2</sub> O	0.213	0.046	0.609	-0.336	0.16
Na <sub>2</sub> O/K <sub>2</sub> O	-0.092	-0.288	0.452	0.179	0.71
CaO+MgO	-0.331	0.05	0.289	-0.153	-0.195
MgO/CaO	0.276	0.196	-0.162	-0.203	0.575

353

 $364 \quad F = (0.338/0.948) \times F1 + (0.281/0.948) \times F2 + (0.146/0.948) \times F3 + (0.11/0.948) \times F4 + (0.073/0.948) \times F5 \quad (6)$ 

Substituting the relevant data of the red beds in Figures 7 and 8 into Equations 1~6 can calculate the quantitative criterion for the red beds:  $F1=-3.36\sim23.55$ ,  $F2=-23.00\sim3.11$ ,  $F3=-10.12\sim4.88$ ,  $F4=-2.21\sim4.52$ ,  $F5=-0.97\sim7.30$ , and  $F=-0.67\sim1.89$ .

# 3.5 Red beds identification quantization criterion verification

The chemical composition combinations of the 15 selected rocks in this study are shown in Table 5. Study has found that, The rapid detection of  $Fe^{2+}$  and  $Fe^{3+}$  is very difficult (Chen et al., 2019) and exceeds the detection range of handheld laser-induced breakdown spectroscopy in this manuscript and similar devices. But this factor does not affect the reliability of the quantification criterion for red beds recognition.  $F1\sim F5$  and F are considered as 6 evaluation indicators, and there are a total of 72 (6 × 12) evaluation indicators for the 12 types of red beds. Among them, 3 evaluation indicators exceed the scope of the quantification criterion for red beds identification (F4 of numbered 7, 9, and 11 red beds with green background in Table 5 is less than the quantification criterion), indicating that the reliability of detecting these 12 types of rocks belonging to the red beds is as high as 95.8%. And for 3 non red beds rocks (limestone, arkose, and mudstone), there are a total of 18 evaluation indicators, of which 13 exceed the scope of the quantification criterion for red beds identification (indicated by blue background), indicating a high reliability of 72.2% in detecting these three types of rocks that do not belong to the red beds. Therefore, this study proposes a quantitative criterion for red beds recognition with high reliability. In the future, if there are new devices that can quickly detect  $Fe^{2+}$  and  $Fe^{3+}$ , the recognition efficiency of the red beds recognition quantification criterion in this study will be higher.

**Table 5.** Chemical composition combinations of 15 kinds of rocks.

NT.	SiO <sub>2</sub>	Al <sub>2</sub> O <sub>3</sub>	TFe <sub>3</sub> O <sub>4</sub>	Na <sub>2</sub> O	K <sub>2</sub> O	MgO	CaO	T24	Fa	E2	TP.4	17.5	T	Rock

14	75.27	12.73	2.22	2.47	4.59	2.67	0.06	36.73	-14.90	-12.11	-12.00	27.27	7.52	Arkose
15	78.33	18.86	1.00	0.25	1.04	0.53	-	26.62	-26.87	-10.13	-1.43	0.02	-0.20	Mudstone

Note: TFe<sub>3</sub>O<sub>4</sub> represents the content of Fe<sub>2</sub>O<sub>3</sub> and FeO. "-" represents that no content was detected. Ignoring "Fe<sub>2</sub>O<sub>3</sub>/FeO" and "MgO/CaO" without values when calculating F1~F5 and F.

# 3.6 Research results application methods

Figure 10 shows the application methods of the research results. According to the methods for emergency management of landslide geological disasters (Fu et al., 2021), landslide risk assessment (including risk identification, risk analysis, and risk assessment) and risk management (developing and selecting treatment plans, as well as planning, implementing, and evaluating treatment methods) need to be carried out before the landslide occurs. In the field of engineering geology, risk identification is the most important prerequisite for landslide emergency response. Red beds is the slippery layer that needs to be identified in risk identification.

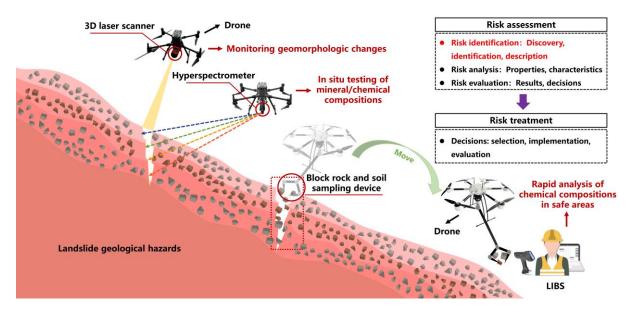

Figure 10. Research results used for risk identification.

At present, the commonly used risk identification method is to use drones to carry image capture devices for three-dimensional reconstruction of slope images, determine the volume of landslide accumulation, and determine the shape changes of the slope (Chen et al., 2020; Fu et al., 2021), which can be also used for mountain rescue (Wankmuller et al., 2021). Based on the drone technology, combined with the Optech Polaris LR 3D laser scanner and the HY-9070 hyperspectral analyzer of Sun Yat-sen University, the landslide shape change and remote monitoring of mineral and chemical compositions can be realized to identify whether it is a red beds landslide. It can also use a drone equipped with a block rock and soil sampling device to collect representative blocks of rock and soil within cracks to a safe area, and then use the YL-P-3LRX Handheld Laser Induced Breakdown

Spectroscopy for rapid analysis. Therefore, the research results can be used for rapid identification of red beds, achieving risk assessment and rapid response of geological disasters such as landslides.

#### 4. Conclusions

- (1) In response to the rapid identification of red beds in geological disaster emergency response, a rapid quantitative identification criterion based on the basic chemical compositions combination rules of red beds has been established, taking into account the correlation between red beds geomorphic characteristics, mineral compositions, and chemical compositions. It solves the current problem of fuzzy identification of the red beds.
- 419 (2) The results indicate that the red beds in the geomorphic characteristics have obvious interlayer 420 characteristics and its appearance is red. In mineral composition, the ratio of clay minerals to other 421 minerals of red beds ranges from 0.11 to 1.50, and the content of hematite of red beds ranges from 1.5% 422 to 10.0%. The following chemical composition combinations can be used as red beds preliminary 423 quantification criterion: SiO<sub>2</sub>+Al<sub>2</sub>O<sub>3</sub> 50.7%~85.0%, Al<sub>2</sub>O<sub>3</sub>/SiO<sub>2</sub>  $0.14 \sim 0.41$ ,  $\approx$  $0.9\% \sim 7.9\%$ , Fe<sub>2</sub>O<sub>3</sub>/FeO 424 FeO+Fe<sub>2</sub>O<sub>3</sub> 1.52~7.70, K<sub>2</sub>O+Na<sub>2</sub>O  $1.6\% \sim 6.8\%$ , 425  $Na_2O/K_2O \approx 0.02 \sim 0.43$ , CaO+MgO  $\approx 0.8\% \sim 9.2\%$ . And the principal component features can serve as a rapid quantitative criterion for distinguishing red beds: F1=-3.36~23.55, F2=-23.00~3.11, F3=-426 427  $10.12 \sim 4.88$ ,  $F4 = -2.21 \sim 4.52$ ,  $F5 = -0.97 \sim 7.30$ , and  $F = -0.67 \sim 1.89$ . The reliability of the quantitative 428 criterion was verified by collecting 15 kinds of rocks and analyzing their chemical composition 429 combinations.
  - (3) The combination of research results with existing landslide geological hazard risk identification techniques can effectively carry out rapid response to geological disasters, which is very important for emergency response to geological disasters. Moreover, the research results can also be applied to the quantitative identification of red beds in other fields such as resources, ecology, environment, energy, materials, etc.
