13  
14 **Abstract.** The Microprocessor without interlocked piped stages (MIPS) and  
15 LoongArch are Reduced Instruction Set Computing (RISC) processor architectures,  
16 which have advantages in terms of energy consumption and efficiency. There are few  
17 studies on the application of MIPS and LoongArch CPUs in the geoscientific numerical  
18 models. In this study, Loongson 3A4000 CPU platform with MIPS64 architecture and  
19 Loongson 3A6000 CPU platform with LoongArch architecture were used to establish  
20 the runtime environment for the air quality modelling system Weather Research and  
21 Forecasting–Comprehensive Air Quality Model with extensions (WRF-CAMx) in  
22 Beijing-Tianjin-Hebei region. The results show that the relative errors for the major  
23 species (NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and PSO<sub>4</sub>) between the MIPS and X86 benchmark  
24 platform are within  $\pm 0.1\%$ . The maximum Mean Absolute Error (MAE) of major  
25 species ranged to  $10^{-2}$  ppbV or  $\mu\text{g m}^{-3}$ , the maximum Root Mean Square Error (RMSE)  
26 ranged to  $10^{-1}$  ppbV or  $\mu\text{g m}^{-3}$ , and the Mean Absolute Percentage Error (MAPE)  
27 remained within 0.5%. The CAMx takes about 195 minutes on Loongson 3A4000 CPU,  
28 71 minutes on Loongson 3A6000 CPU and 66 minutes on Intel Xeon E5-2697 v4 CPU,  
29 when simulating a 24h-case with four parallel processes using MPICH. As a result, the

30 single-core computing capability of Loongson 3A4000 CPU for the WRF-CAMx  
31 modeling system is about one-third of Intel Xeon E5-2697 v4 CPU and Loongson  
32 3A6000 CPU is slightly lower than Intel Xeon E5-2697 v4 CPU, but the thermal design  
33 power (TDP) of Loongson 3A4000 is 40W, while the Loongson 3A6000 is 38W, only  
34 about one-fourth of Intel Xeon E5-2697 v4, whose TDP is 145W. The results also verify  
35 the feasibility of cross-platform porting and the scientific usability of the ported model.  
36 This study provides a technical foundation for the porting and optimization of  
37 numerical models based on MIPS, LoongArch or other RISC platforms.

38

## 39 **1 Introduction**

40 In the recent years, with the increasing demand for high-performance computing  
41 resources and rapid development in the computer industry, especially supercomputer,  
42 central processing unit (CPU) has undergone significant advancements in logical  
43 structure, operational efficiency, and functional capabilities, making it the core  
44 component of current computer technology development. There are two main types:  
45 one is complex instruction set computer (CISC) CPU (George, 1990; Shi, 2008), mainly  
46 using X86 architecture, representative vendors including Intel, AMD, etc., and widely  
47 used in high-performance computing platforms. The other is reduced instruction set  
48 computer (RISC) CPU (Mallach, 1991; Liu et al.,2022), mainly using ARM, MIPS,  
49 RISC-V and other architectures, representative vendors including Loongson, etc., and  
50 mainly used in high-performance computing platforms, which have high efficiency,  
51 excellent stability and scalability. The Microprocessor without interlocked piped stages  
52 (MIPS) architecture is one of the significant representatives of RISC architecture. MIPS  
53 was originally developed in the early 1980s by Professor Hennessy at Stanford  
54 University and his group (Hennessy et al., 1982). The simplicity of the MIPS instruction  
55 set contributes to its ability to process instructions quickly, thus achieving higher  
56 performance even in low-power conditions. In 1999, MIPS Technology Inc. released  
57 the MIPS32 and MIPS64 architecture standard (MIPS Technology Inc., 2014).  
58 Compared to the CISC CPUs, RISC CPUs demonstrate excellent performance and

59 power efficiency, which have gained popularity among chip manufacturers.

60 The Loongson processor family developed by Loongson Technology is mainly  
61 designed using MIPS architecture and Linux operating system (Hu et al, 2011), which  
62 has rich application tools in Linux open-source projects. The main reason that currently  
63 restricts the development of CPUs that implement non-X86 instruction set architecture  
64 such as MIPS64 is the immature software ecosystem (Hu et al., 2016). Based on the  
65 strategy of open-source software, Loongson platform has gained abundant software  
66 tools, making it possible to further develop scientific computing and numerical models.

67 Air quality model (AQM) systems use mathematical equations and algorithms to  
68 simulate and predict the pollutant concentration in the atmosphere. The current AQMs  
69 have become more complex, incorporating numerous factors such as emissions from  
70 industrial sources, vehicle traffic, and natural sources, as well as meteorological  
71 conditions, including modeling meteorology, emissions, chemical reactions, and  
72 removal processes (Zhang et al., 2012). Regional-scale AQMs have been widely used  
73 to predict air quality in cities, formulate emission reduction strategies, and evaluate the  
74 effectiveness of control policies (Wang et al., 2023), including the Community  
75 Multiscale Air Quality (CMAQ) modelling system (Appel et al., 2017; Appel et al.,  
76 2021), the Comprehensive Air Quality Model with extensions (CAMx; RAMBOLL  
77 ENVIRON Inc., 2014), and the Nested Air Quality Prediction Modeling System (Wang  
78 et al., 2006; Chen et al., 2015). Due to the requirement of meteorological input,  
79 commonly used offline meteorological models such as WRF (Michalakes et al., 2001)  
80 are coupled offline with the regional AQMs to provide meteorological and chemical  
81 forecast as the WRF-AQM modeling system, such the WRF-CMAQ modeling system  
82 (Wu et al., 2014).

83 Both the meteorological and air quality numerical simulation rely heavily on high-  
84 performance computing systems. The WRF-AQM systems can run stably on high-  
85 performance computing platforms based on X86 or X86-compatible instruction set  
86 architecture (ISA) CPUs, which account for the highest percentage among the main  
87 processors of current high performance computing platforms. There are relatively  
88 limited researches on the application of WRF-AQM system on MIPS and LoongArch

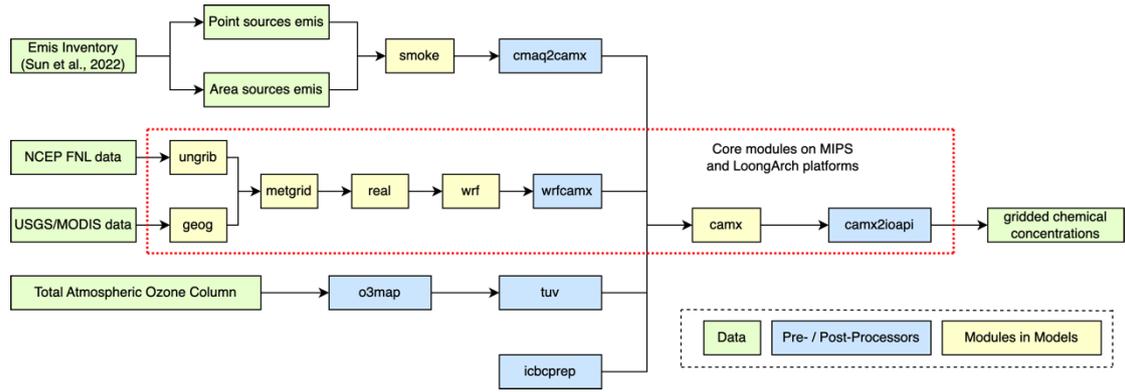

89 CPU platforms at present, this study focuses on the application of WRF-CAMx model  
90 on Loongson CPU platform based on the MIPS and LoongArch architectures. A  
91 simulation case covering the Beijing-Tianjin-Hebei region was set up to evaluate the  
92 differences and performance between MIPS and X86 platforms. This study validated  
93 the stability of scientific computing on MIPS and LoongArch CPU platform, and it  
94 offered technical references and evaluation methods for the porting and application of  
95 numerical models on non-X86 platforms.

96 Section 2 provides the model descriptions of the Weather Research and  
97 Forecasting–Comprehensive Air Quality Model with extensions (WRF-CAMx)  
98 modeling system, and the descriptions of MIPS, LoongArch and benchmark platforms.  
99 The configuration of the air quality numerical simulation system and simulation case  
100 are also presented in Section 2. Section 3 describes porting and optimization of the  
101 WRF-CAMx modelling system on MIPS and LoongArch CPU platforms. Section 4  
102 analyzes the differences of model results between MIPS CPU platform and the  
103 benchmark platform. Section 5 discusses MIPS and LoongArch CPUs performance in  
104 scientific computing. The conclusions are presented in Section 6.

105

## 106 **2 Model and Porting Platform Description**

107 The air quality modeling system was constructed using the WRF v4.0 model  
108 developed by National Center for Atmospheric Research (NCAR) (Skamarock et al.,  
109 2019), and the CAMx v6.10 developed by Ramboll Environment (RAMBOLL  
110 ENVIRON Inc., 2014), as shown in Figure 1. And the Loongson 3A4000 CPU platform  
111 was chosen for the porting work in the study. This study introduced the porting of WRF-  
112 CAMx modeling system to MIPS and LoongArch CPU platforms.

113

114 **Figure 1.** Framework of WRF-CAMx modeling system. The core modules have been  
 115 ported to MIPS and LoongArch CPU platforms. The core modules are framed by red  
 116 dashed line in the figure.

117 In Xi'an, China and Milan, Italy, the WRF-CAMx modelling system was applied ,  
 118 enabling high-resolution hourly model output of pollutant concentration within specific  
 119 local urban areas (Pepe et al., 2016; Yang et al., 2020). The modeling system is widely  
 120 used to study the spatial-temporal variation of pollutant concentration and source  
 121 apportionment, analyze the contribution of regional transport to pollution and  
 122 investigate the impact of initial conditions and emissions on pollution simulation in key  
 123 regions such as the North China Plain, Sichuan Basin, and Fenwei Plain (Bai et al.,  
 124 2021; Zhen et al., 2023; Zhang et al., 2022; Xiao et al., 2021).

125

## 126 2.1 Description of WRF-CAMx modeling system

127 WRF and CAMx serve as the core components of the modeling system. WRF is a  
 128 mesoscale numerical weather prediction system designed for atmospheric research and  
 129 operational forecasting applications. Distinguished by its high temporal and spatial  
 130 resolution, WRF is suitable for multi-scale simulations of short-term weather forecast,  
 131 atmospheric process, and long-term climate, making it an essential tool in the  
 132 meteorological and atmospheric research communities (Powers et al., 2017). In the  
 133 modeling system, WRF provided gridded meteorological field data for air quality  
 134 model CAMx. The relative humidity, a meteorological variable used in result validation  
 135 is calculated using the wrf-python package (Official website: [https://wrf-](https://wrf-python.readthedocs.io)  
 136 [python.readthedocs.io](https://wrf-python.readthedocs.io), last access: October 2023). CAMx is an atmospheric pollutant

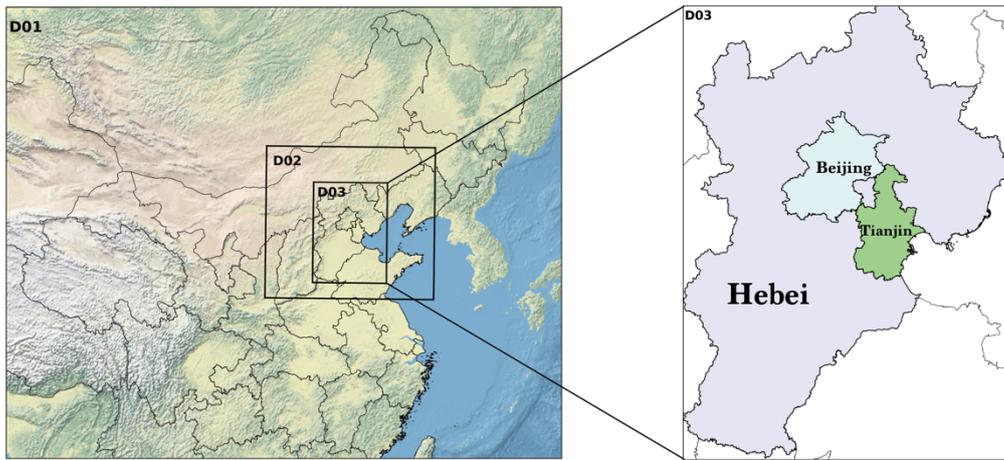

137 calculation model, which can be utilized for simulating and predicting the  
138 concentrations of various air pollutants. The WRF and CAMx models are distinguished  
139 by modularity and parallelism, using MPI in parallel computing, making them efficient  
140 (Skamarock et al., 2019; RAMBOLL ENVIRON Inc., 2014).

141 In the modeling system, the SMOKE model and cmaq2camx program are used to  
142 process emission data and provide model-ready gridded emission data for the CAMx  
143 model. The wrfcamx program converts the WRF results into meteorological input files  
144 which are compatible with CAMx. TUV is a radiation transfer model capable of  
145 producing clean sky photolysis rate input files for the chemical mechanisms in CAMx,  
146 and the o3map program prepares ozone column input files for TUV and CAMx. The  
147 icbcprep program prepares initial and boundary condition files for CAMx with the  
148 profile, and the effects of initial conditions have been studied by Xiao et al. (2021). The  
149 camx2ioapi program converts the CAMx output files into netCDF format following the  
150 Models-3/IO-API convention, and then uses NCL or other softwares to analyses the  
151 model results.

152

### 153 **2.1.1 Model domain setup**

154 The model domain focusing on the Beijing-Tianjin-Hebei region has been set up  
155 in this study. The WRF model has three nested domains with horizontal resolutions of  
156 27km (D1), 9km (D2), and 3km (D3), as shown in Figure 2. The outer domain (D1)  
157 covers most parts of China, and the inner domain (D3) covers Beijing, Tianjin, and  
158 Hebei Province. The model domain is centered at (35°N, 110°E), with two true latitudes  
159 located at 20°N and 50°N. The vertical resolution of WRF is 34 vertical layers. The  
160 CAMx model has only one model domain, which is the innermost grid with a resolution  
161 of 3km (D3), mainly covering the Beijing-Tianjin-Hebei region. The vertical resolution  
162 of CAMx is 14 vertical layers, which is extracted from the WRF output files using the  
163 wrfcamx module, and the lower seven layers of CAMx are same as those in the WRF  
164 model.

165

166 **Figure 2.** The domains of three-level nested grids in the WRF-CAMx modelling system.

167 The respective horizontal resolutions are  $27 \text{ km} \times 27 \text{ km}$  (D1),  $9 \text{ km} \times 9 \text{ km}$  (D2), and

168  $3 \text{ km} \times 3 \text{ km}$  (D3).

169

### 170 **2.1.2 Model configuration**

171 Starting from 00:00 on November 3, 2020, until 24:00 on November 5, 2020, the  
172 modelling system simulated the meteorological and air quality for a period of 72 hours.

173 In the research of Wang et al. in 2019, a 72h test case was set for the scientific validation  
174 and performance evaluation of the chemistry transport models. A 72h case represents a

175 moderate-sized real scientific workload, which allows for simulating in a short time to  
176 validate the results and assess computational efficiency on the MIPS and LoongArch

177 platforms. For the meteorological model, the global meteorological initial and boundary  
178 fields for the WRF model are derived from the NCEP Global Final Reanalysis Data

179 (FNL), with a spatial resolution of  $0.5^\circ \times 0.5^\circ$  and a temporal resolution of 6 hours. And  
180 the parameterization schemes of the WRF model used in the simulation case are shown

181 in Table 1.

182 For the air quality model, the meteorological files are provided by the WRF model  
183 are used for the chemical transport module in CAMx. The emission inventory used in

184 the simulation case was obtained from Sun et al. (2022a). It contains basic emissions  
185 from Sun et al. (2022b) and fugitive dust emission from bare ground surfaces. The

186 SMOKE model (v2.4) is used to process the emission inventory and provide gridded

187 emissions for CAMx. The parameterization schemes of the CAMx model used in the  
 188 simulation case are shown in Table 2.

189

190 **Table 1.** Parameterization schemes of WRF in research case.

Parameterization process	Scheme
Microphysics	WSM3
Longwave radiation	RRTM
Shortwave radiation	Dudhia
Land surface	Noah
Planetary boundary layer	YSU
Cumulus parameterization	Kain-Fritsch(new Eta)

191

192 **Table 2.** Parameterization schemes of CAMx in research case.

Parameterization process	Scheme
Horizontal Diffusion	PPM
Vertical Diffusion	K-theory
Dry Deposition	Zhang03
Gas-phase chemical mechanism	CB05
Aqueous aerosol chemistry	RADM-AQ
Inorganic gas-aerosol partitioning	ISORROPIA

193

### 194 **2.1.3 Statistical indicators for model results**

195 To quantify the differences in the model results between the MIPS and benchmark  
 196 platform, three statistical indicators are used to analyze the differences of concentration  
 197 time series: Mean Absolute Error (MAE), Root Mean Square Error (RMSE), and Mean  
 198 Absolute Percentage Error (MAPE). The MAPE quantifies the deviation between  
 199 computational differences and simulated values. The smaller these indicators, the better  
 200 accuracy and stability of scientific computing of the modeling system on the MIPS  
 201 platform. The calculation formulas for these statistical indicators are provided in  
 202 equations (1) to (3).

$$203 \quad MAE = \frac{1}{n} \sum_{i=1}^n |MIPS(i) - Base(i)| \quad (1)$$

$$204 \quad RMSE = \left[ \frac{1}{n} \sum_{i=1}^n (MIPS(i) - Base(i))^2 \right]^{\frac{1}{2}} \quad (2)$$

$$205 \quad MAPE = \frac{1}{n} \sum_{i=1}^n \left| \frac{MIPS(i) - Base(i)}{MIPS(i)} \right| \times 100\% \quad (3)$$

206 In the equations,  $n$  represents the number of grids in the domain.  $MIPS(i)$  represents the  
207 simulated value of a certain grid on the MIPS platform, and  $Base(i)$  represents the  
208 baseline value of a certain grid on the benchmark platform.

209

## 210 **2.2 MIPS and LoongArch CPU platforms description**

211 Loongson CPU platform was chosen for the porting work in the study. Currently,  
212 the Loongson processor family has three generations of CPU products, evolving from  
213 single-core to multi-cores architectures and from experimental prototypes to mass-  
214 produced industrial products (Hu et al., 2011). The Loongson-2 processor is a 64-bit  
215 general-purpose RISC processor series which is compatible with MIPS instruction set.  
216 It can be used in personal computers, mobile terminals, and various embedded  
217 applications, running many operating systems such as Linux and Android smoothly  
218 (Zhi et al., 2012). Wu et al. (2019) reports the application of the mesoscale model on  
219 Loongson 2F CPU platform. The Loongson-3 processor features a scalable multi-core  
220 architecture, targeting high-throughput data centers, high-performance scientific  
221 computing, and other applications, with the significant advantage of achieving a high  
222 peak performance-to-power ratio and striking a well-balanced trade-off between  
223 performance and power consumption (Hu et al., 2009).

224 The Loongson 3A series are multi-core processors designed for high-performance  
225 computers, featuring with high bandwidth, and low power consumption. The efficient  
226 design solution and the advantage of high energy efficiency ratio make servers based  
227 on Loongson CPUs highly competitive in performance, power consumption, and cost-  
228 effectiveness (Li et al., 2014; Wang et al., 2014). In this study, the Loongson platform  
229 uses the Debian Linux operating system, commercially known as Tongxin UOS  
230 (<https://www.uniontech.com>, last access: January, 2024), and the Loongson 3A4000  
231 processor, which is the first quad-core processor based on GS464v 64-bit  
232 microarchitecture in Loongson 3 Processor Family. The main technical parameters of  
233 Loongson 3A4000 CPU are shown in Table 3. Compared to previously released CPUs,  
234 the processor improves frequency and performance by optimizing on-chip interconnect  
235 and memory access path, integrating 64-bit DDR4 memory controller and on-chip

236 security mechanism. The Loongson 3A6000 CPU platform uses Loongnix, the open-  
 237 source community edition operating system released by Loongson  
 238 (<https://www.loongson.cn/system/loongnix>, last access: January, 2024), and the latest  
 239 released Loongson 3A46000 processor, which is a quad-core processor based on LA664  
 240 microarchitecture. The main technical parameters of Loongson 3A6000 CPU are shown  
 241 in Table 3. The processor supports the LoongArch™ instruction set and hyper-threading,  
 242 and the performance has significantly improved compared to the previously released  
 243 processors (Hu et al., 2022).

244

245 **Table 3.** Main Parameters of Loongson 3A4000 CPU and Loongson 3A6000 CPU\*

### 248 **2.3 Benchmark platform description**

249 This study uses an X86 CPU platform as benchmark platform compared to the  
 250 MIPS and LoongArch CPU platforms. The benchmark platform is powered by Intel  
 251 Xeon E5-2697 v4 CPU, with strong floating-point performance and many technical  
 252 features such as Intel Turbo Boost Technology (Intel Inc., 2023). The Intel Xeon E5-  
 253 2697 v4 CPU has 18 cores, with 2.3GHz base frequency and 3.6GHz maximum Turbo  
 254 Boost frequency, 45 MB Intel Smart Cache and 145W design power consumption. The  
 255 operating system is CentOS Linux 7.4.1708. The main information for all platforms is

256 shown in Table 4.

257

258 **Table 4.** The comparison of main configuration between MIPS, LoongArch and X86  
259 platforms.

261

## 262 **2.4 The difference between MIPS, LoongArch and X86 platforms**

263 In this study, the numerical model's source code is written in Fortran, and  
264 commonly used compilers for X86 architecture include Intel Compiler, PGI and GNU  
265 Compiler. The compiler for MIPS platform is built using GCC 8.3 MIPS GNU/Linux  
266 cross-toolchain based on the open-source GNU Project, called MIPS GNU, and the  
267 latest version is 8.3. And the compiler for LoongArch platform is built using GCC 8.3  
268 LoongArch GNU/Linux cross-toolchain based on the open-source GNU Project, called  
269 LoongArch GNU, and the latest version is 8.3. The compiler for the benchmark  
270 platform is set to X86 GNU, and the version is also 8.3. Table 5 shows the differences  
271 between all platforms' GNU compilers in terms of applicable platforms. Compared to  
272 X86 GNU, the default compilation options of MIPS GNU compiler not only specify  
273 the platform architecture but also include additional instruction sets, such as atomic

274 operation instruction set LLSC, shared library instruction set PLT, etc., which can  
 275 optimize target programs compiled by GNU for MIPS architecture and improve  
 276 computational efficiency. And the default compilation options of LoongArch GNU  
 277 compiler not only specify the platform architecture but also include target  
 278 microarchitecture tuning option, which can also optimize target programs compiled by  
 279 GNU for LoongArch architecture.

280 **Table 5.** Comparison of GNU compiler between MIPS, LoongArch and X86 CPU  
 281 platforms.

<b>Artitecture</b>	<b>MIPS64</b>	<b>LoongArch</b>	<b>x86_64</b>
<b>Compiler</b>	MIPS GNU Fortran	LoongArch GNU Fortran	X86 GNU Fortran

<b>Options (Architecture)</b>	-march=mips64r2 -mabi=64	-march=loongarch64 -mabi=lp64d	-march=x86-64 -mtune=generic
<b>Options (Instruction set)</b>	-mllsc -mplt - mmadd4	-mtune=loongarch64	/
<b>FLAGS(WRF)</b>	-fconvert=big-endian -frecord-marker=4 -ffree-line-length-none -O2 -ftree-vectorize -funroll-loops		
<b>FLAGS(CAMx)</b>	-fconvert=big-endian -frecord-marker=4 -ffixed-line-length-none -fno-align-commons -O2		

282 The WRF-CAMx modeling system depends on several scientific computing  
 283 libraries. Firstly, the general data format libraries netCDF and HDF5 are required to  
 284 store the large-scale gridded data for the modeling system. NetCDF is a self-describing  
 285 data format developed by NCAR/Unidata, primarily used for storing multidimensional  
 286 array data in fields like meteorology and earth sciences (UCAR/Unidata, 2021). HDF5  
 287 is a data format developed by HDF GROUP that supports complex data structures with  
 288 multiple data types and multi-dimensional datasets (The HDF Group, 2019). In this  
 289 study, netCDF-C (v4.8.1), netCDF-Fortran (v4.5.3), HDF5 (v1.12.1) and IOAPI (v3.1)  
 290 were successfully installed on MIPS and LoongArch platforms by building from their  
 291 sources, which are obtained from the official website.

292 The MPICH library is required to support parallel computing in the modeling  
 293 system. In order to fully utilize computing resources, the method of MPI message

294 communication is used in WRF and CAMx model (Wu et al., 2012). MPICH is an  
295 open-source, portable parallel computing library for implementing the MPI standard  
296 (Amer et al., 2021). It supports inter-process communication and data exchange in the  
297 parallel computing environment. Similarly, this study successfully installed MPICH  
298 (v3.4) on MIPS and LoongArch platforms by building from its source. During the  
299 compilation and installation of the mentioned libraries above, the configure tool was  
300 used to check the basic information of the platform's CPU and compiler, and prepare  
301 for compatibility with platform before compilation, the GNU compiler is used to  
302 compile the source code of libraries, and the cmake tool is used to install the libraries.  
303 Additionally, the same runtime environment as MIPS platform was also built on the  
304 benchmark platform.

305

### 306 **3 Porting the WRF-CAMx modelling system on MIPS and LoongArch** 307 **CPU platforms**

308 The simulation result is influenced by several factors including processor  
309 architecture, operating system, compiler, parallel environment, and scientific  
310 computing libraries. In order to ensure stability and accuracy of numerical simulation,  
311 the models should be adapted to the new runtime environment when porting across  
312 platforms. Additionally, various operating systems have different tools, software and  
313 libraries, which may impact the results of numerical simulations.

314 In this study, the runtime environment for WRF-CAMx modeling system was built  
315 on MIPS and LoongArch platforms, including parallel computing libraries such as  
316 MPICH3 (v3.4) and data format libraries such as HDF5 (v1.15.1) and NETCDF (C-  
317 v4.8.1, Fortran-v4.5.3). These libraries do not support the architecture (mips64el and  
318 LoongArch) and GNU compiler of Loongson platform. Relevant information needs to  
319 be added to the free software config.guess and config.sub provided by GNU org. Part  
320 of the information is shown in subfigure a) in Figure 3, which can help identify the  
321 platform architecture and system during the compilation and installation of libraries  
322 using Configure and Make tools. The configuration files for making the models were

323 modified to fit the compilers of the Linux system on MIPS and LoongArch platforms.  
324 In order to verify the stability of scientific computing on MIPS and LoongArch  
325 platforms, a control experiment was set up on the benchmark platform, minimizing the  
326 impact of other factors on simulation results of both platforms.

327 The WRF v4.0 and CAMx v6.10 were successfully deployed on MIPS and  
328 LoongArch platforms through source code compilation and installation. In the WRF  
329 model, the default options for GNU compiler which are suitable for MIPS and  
330 LoongArch architecture CPUs are not provided in the configure file of the source code  
331 package, and it is necessary to incorporate architecture-specific settings for the model.  
332 For example, the architecture presets are stored in the configure.defaults file, but  
333 settings about the Loongson platform is not included. Specific architecture details,  
334 including CPU architecture, GNU compiler and compilation flags, need to be added,  
335 which can ensure the correct display of configuration during building WRF model, and  
336 part of information is shown in subfigure b) in Figure 3. Table 5 provides the detailed  
337 information added in the configure file, mainly about MIPS and LoongArch GNU  
338 Fortran. When compiling Fortran programs on MIPS and LoongArch platforms, the  
339 MIPS and LoongArch GNU Fortran and necessary compilation flags must be specified.  
340 These flags include common Fortran file format flags such as `-fconvert=big-endian` and  
341 `-frecord-marker=4`, as well as optimization flags such as `-O2 -fvec-extend -funroll-`  
342 `loops`. By specifying the appropriate compiler and flags for MIPS and LoongArch  
343 architectures, the configure tool will provide necessary settings to compile WRF.  
344 Correspondingly, when compiling WRF on the benchmark platform, the compilation  
345 flags are strictly consistent with those of MIPS and LoongArch CPU platforms, which  
346 ensures that differences in simulation results of two platforms are primarily attributed  
347 to the underlying hardware architecture rather than changes in compilation settings.

348 In the CAMx model, the makefile provides information about parallelism and  
349 compilers. Similarly, information about the CPU architecture, GNU compiler, and  
350 compilation flags on MIPS and LoongArch platforms also needs to be added in the  
351 makefile. For the detailed information added in the makefile, please refer to Table 5.  
352 Additionally, the code of CAMx was modified to make it run smoothly on MIPS and

353 LoongArch platform. Taking some function in the CAMx model for example, the model  
354 frequently uses the “write” function for formatted output. The format specifiers in the  
355 parameters consist of data types (I, F, E, A, X, etc.) followed by a character width. In  
356 the CAMx model, the format specifiers in the write function mostly default to character  
357 width, but there is a compilation issue with MIPS GNU, requiring character width  
358 descriptors. It is also essential to ensure consistency with the default precision. A  
359 specific example is illustrated in the figure below. A specific example is showed in in  
360 subfigure c) in Figure 3. So far, the WRF-CAMx model has been successfully compiled  
361 and installed on the MIPS and LoongArch platforms after modifications of the  
362 configuration files mentioned above.

## 368 4 The differences of model results on the two platforms

### 369 4.1 Validation of the spatial distribution

370 A 72h simulation case has been designed to test the stability and availability of the  
 371 WRF-CAMx modeling system on the MIPS CPU platform in Beijing. By analyzing the  
 372 differences in simulation results and computing time, the accuracy and performance of

373 the modeling system on MIPS platform were evaluated, which further verifies the  
 374 feasibility and stability of the modeling system after porting to the MIPS platform.

375 Common meteorological variables, including 2-meter temperature, land surface  
 376 pressure, and relative humidity were selected to verify the WRF model results. Figure  
 377 3 shows the spatial distribution of the four meteorological variables after 72 hours  
 378 simulation on different platforms, as well as the absolute errors (AEs). The  
 379 meteorological variables from the modeling system on the different platforms exhibit a  
 380 generally consistent spatial distribution in the Beijing-Tianjin-Hebei regions shown in  
 381 Figure 3.

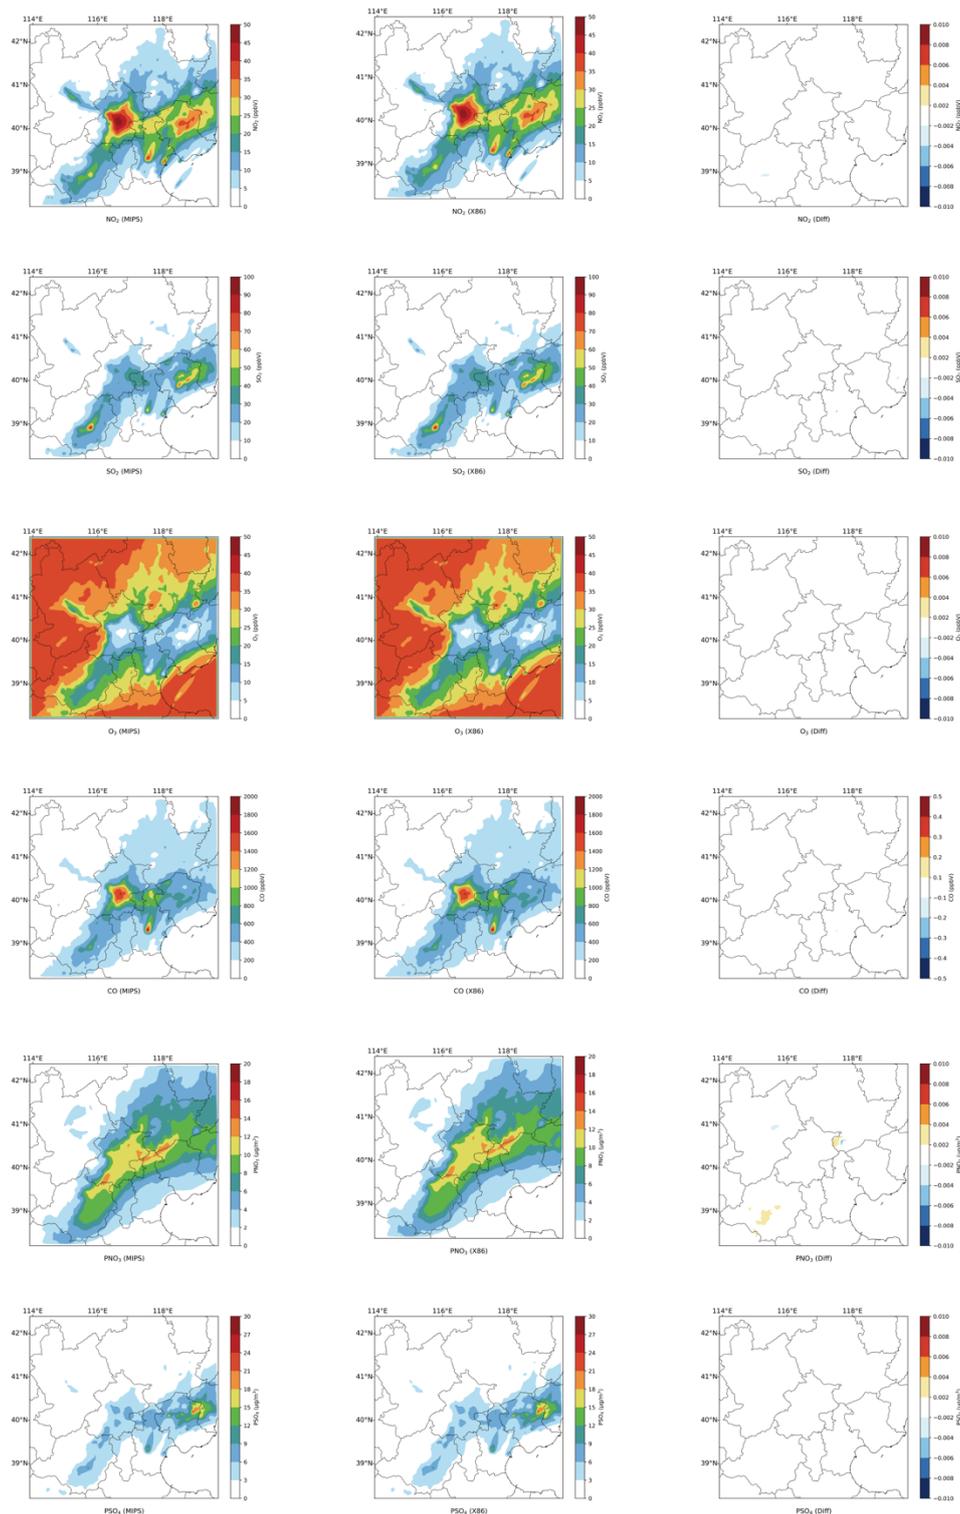

382  
 383 **Figure 4.** Spatial distribution of 2m temperature, surface pressure, relative humidity  
 384 from WRF. Left column, MIPS platform. Middle, the X86 platform. Right, the  
 385 differences between the MIPS and benchmark(X86) platform.

386

387 Similarly, the NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and PSO<sub>4</sub> were selected to verify the

388 CAMx model results on the MIPS platform. Figure 4 shows the spatial distribution of  
389 the six species, as well as the absolute errors (AEs) between the two platforms after 72  
390 hours simulation. Simulating the 72h-case with four parallel processes using MPICH,  
391 CAMx takes about 9h on Loongson 3A4000 CPU and 2.6h on Intel Xeon E5-2697 v4  
392 CPU. As shown in Figure 4, the spatial distribution of air pollution concentrations from  
393 the different platforms is essentially consistent, appearing very similar visually.

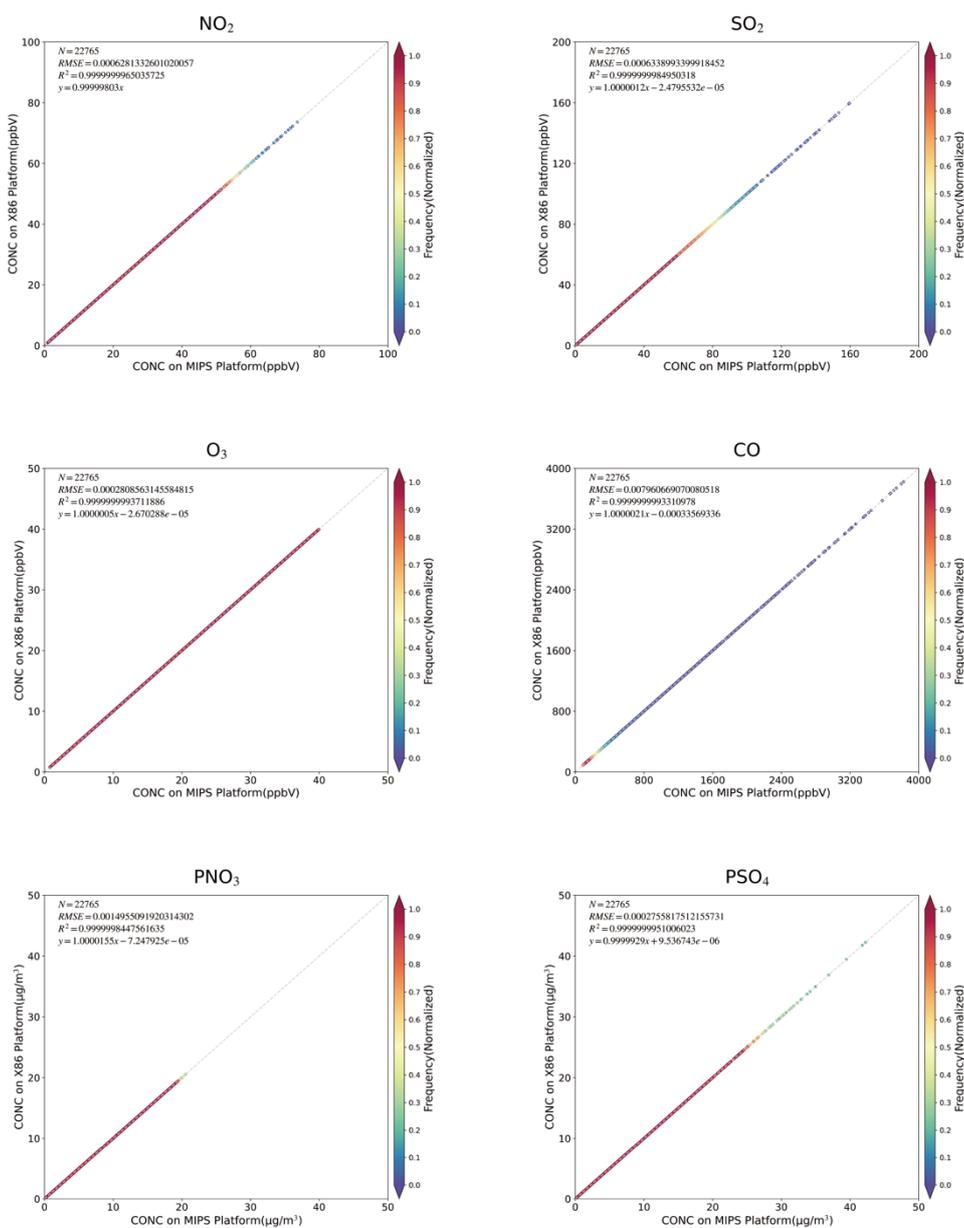

394

395 **Figure 5.** Spatial distribution of NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and PSO<sub>4</sub> from CAMx on  
 396 MIPS and benchmark platform. Left column, MIPS platform. Middle, the X86 platform.  
 397 Right, the differences between the MIPS and benchmark(X86) platform.

398 As shown in Figure 5, the scatter plots between the two platform, it can be seen

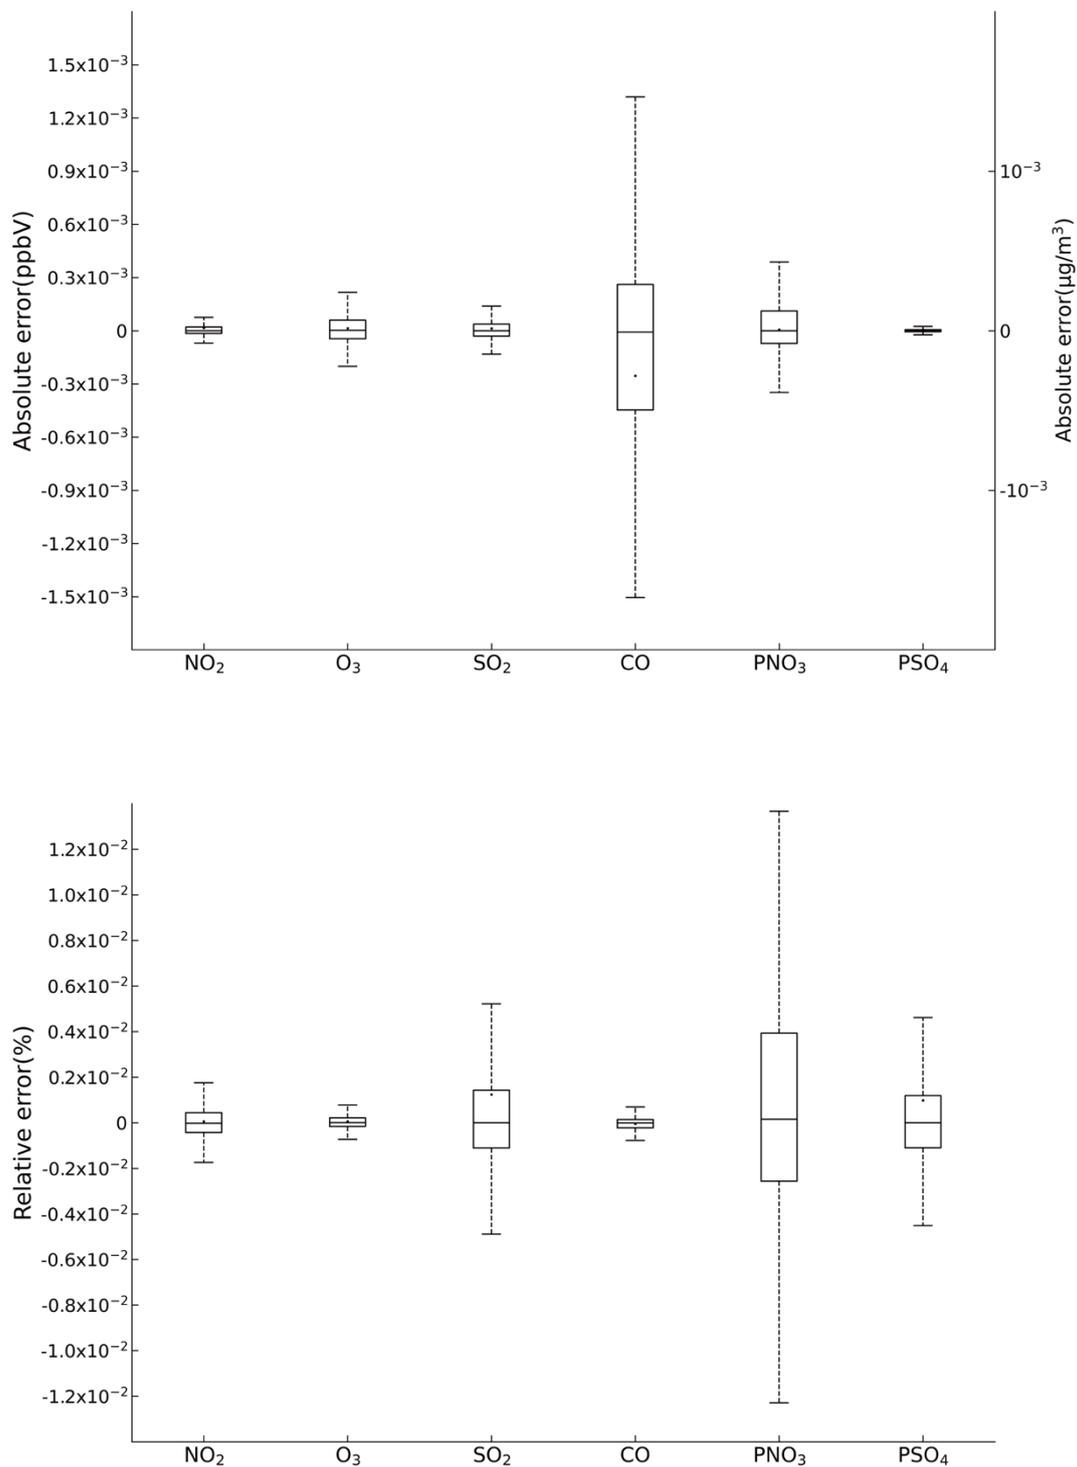

399 that for the total of 22,765 grids within the 145x157 simulation domain, the root mean  
 400 square errors (RMSEs) of the six species between the MIPS platform and benchmark  
 401 platform are close to 0.001, which is essentially 0. The linear regression model was  
 402 used to fit the scatters, and the regression slopes for each species are nearly 1, with  
 403 intercepts close to 0, and the R2 values used for the goodness of fit are nearly 1. The  
 404 fitted lines closely coincide with the “y=x” line, indicating that the differences between  
 405 the MIPS and X86 platform for each species are minimal to negligible.

406  
 407 **Figure 6.** Scatter of grid concentrations for NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and PSO<sub>4</sub> from  
 408 CAMx on the MIPS and benchmark platform. The density of scatters is represented by

409 the colors.

410 Figure 6 is the boxplots which show the absolute errors (AE) and relative errors  
411 (RE) of the six species between MIPS and benchmark platform. According to Figure 6,  
412 the absolute errors of the six species are generally in the range of  $\pm 10^{-3}$  ppbv (parts per  
413 billion by volume; the unit of  $\text{NO}_2$ ,  $\text{SO}_2$ ,  $\text{O}_3$  and CO concentration) or  $\mu\text{g m}^{-3}$  (the unit  
414 of particle composition  $\text{PNO}_3$  and  $\text{PSO}_4$ ), and the relative errors are generally in the  
415 range of  $\pm 0.01\%$ . Specially for CO, it exhibits more pronounced AEs compared to other  
416 species. In some grid boxes, the AEs between MIPS and benchmark platform exceed  
417 the range of  $\pm 10^{-3}$  ppbv, but they remain in the range of  $\pm 10^{-2}$  ppbv. In summary, there  
418 are some errors between the results of the modeling system on the MIPS and benchmark  
419 platform during the porting process. However, these errors are relatively minor  
420 compared to the numerical values. The reasons are attributed to the differences in the  
421 CPU architecture and compiler characteristics between the two platforms, such as data  
422 operations and precision running on different CPUs, which are primarily responsible  
423 for the observed errors.

424

425 **Figure 7.** The absolute errors and relative errors for NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and PSO<sub>4</sub>  
 426 concentration in all grids between the MIPS and benchmark platform.

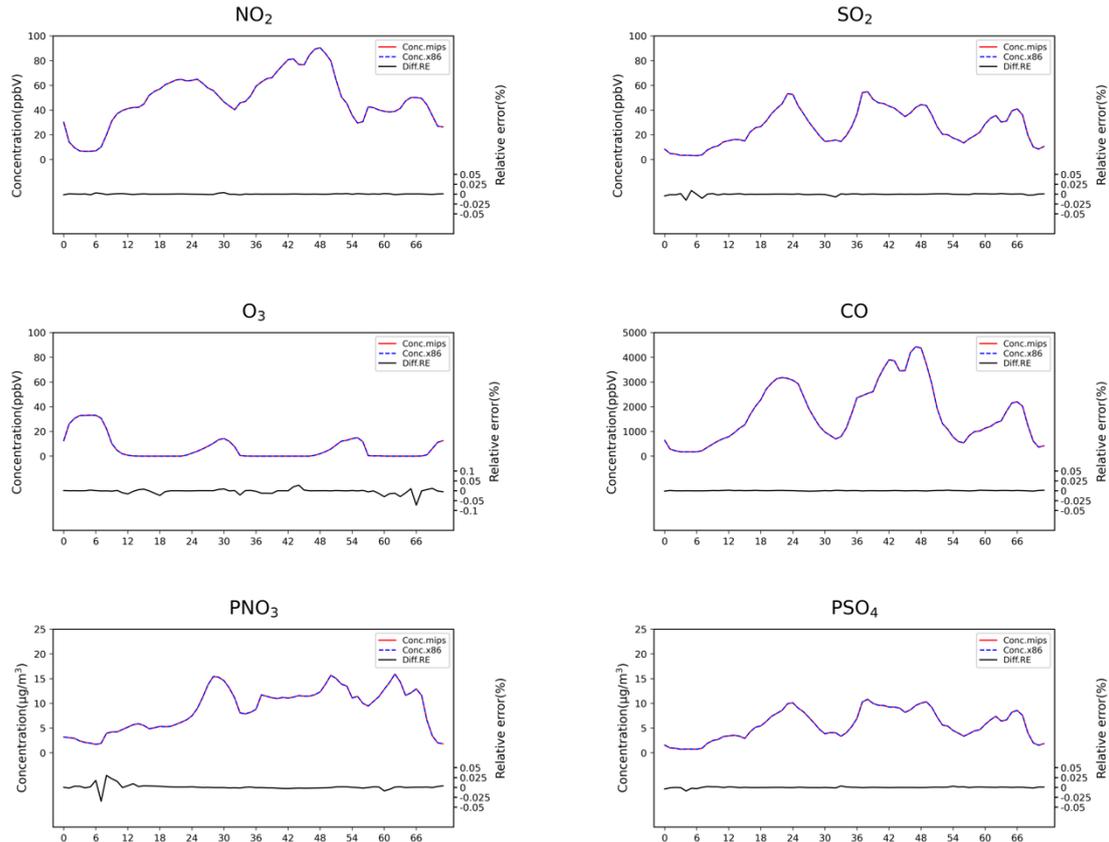

427 Additionally, random grids in the domain were selected to assess the precision of  
 428 simulation results in localized regions. The positions of these grids were determined

429 based on 32 observation stations in Beijing, and the nearest grid was determined using  
430 the Euclidean Shortest Distance in the domain. The station map is presented in Figure  
431 S1 in the Supplement. The Taylor diagram is used to assess the precision of  
432 concentrations for six species near the observation stations, and the scatters  
433 representing the six species at 32 stations are highly overlapping. Statistical parameters  
434 used in the Taylor diagram, such as the correlation coefficient (R) approaching 1,  
435 normalized standard deviation (NSD) and normalized root mean square error (NRMSE)  
436 approaching 0, indicate high precision of the simulation results at specific stations on  
437 the MIPS platform.

438

#### 439 **4.2 Validation of the temporal distribution from the two platform**

440 The time series of computational differences also be evaluated in this study.  
441 Random grid in the domain was selected to examine the hourly concentrations of the  
442 six species. Taking the example of the Beijing Olympic Center station (116.40°E,  
443 39.99°N) from the National Standard Air Quality (NSAQ) stations, the time series of  
444 hourly concentrations in the grid of the Beijing Olympic Center station and relative  
445 errors between the MIPS and benchmark platform over the 72-hour period were shown  
446 in Figure 7. As shown in Figure 7, it can be seen that the time series of the air pollutant  
447 concentrations were highly consistent between the two platforms. In the 72-hour period,  
448 the relative errors for NO<sub>2</sub>, SO<sub>2</sub>, CO and PSO<sub>4</sub> remain in ±0.025%. For PNO<sub>3</sub>, the  
449 relative errors remain in ±0.05%, and for O<sub>3</sub>, they remain in ±0.1%. This indicates that  
450 the errors caused by different architectures are within a reasonable range.

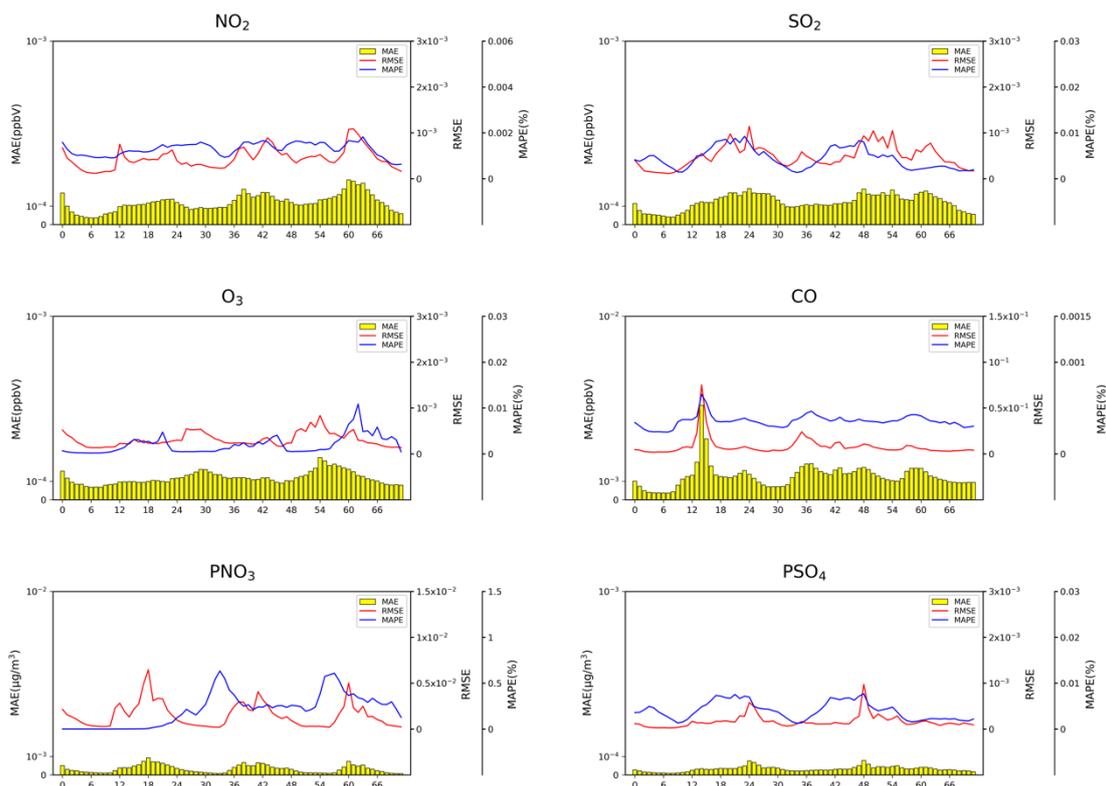

451

452 **Figure 8.** Time-series of NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and PSO<sub>4</sub> concentrations and its  
 453 relative errors (RE) at the Beijing Olympic Sports Center site between the MIPS and  
 454 X86 platform. The red solid line and the blue dashed line, the CAMx model results on  
 455 MIPS platform and X86 platform. The black solid line shows the relative errors (RE)  
 456 between the MIPS and X86 platform.

457

458 Figure 8 shows the time series of the concentration and their statistical indicators,  
 459 MAE, RMSE, and MAPE during the 72-hour simulation. As show in the figure, for  
 460 NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, and PSO<sub>4</sub>, the MAEs are all below 10<sup>-3</sup> ppbv (µg m<sup>-3</sup>), and the RMSEs  
 461 are all below 10<sup>-3</sup>. The MAEs for CO and PNO<sub>3</sub> are below 10<sup>-2</sup> ppbv (µg m<sup>-3</sup>), and the  
 462 RMSEs for PNO<sub>3</sub> are below 10<sup>-2</sup>, while the RMSEs for CO are below 10<sup>-1</sup>. This is  
 463 because that PNO<sub>3</sub> and CO have relatively higher background concentrations compared  
 464 to the other species. The MAPE of PNO<sub>3</sub> concentration mainly ranging in 0-0.5%, while  
 465 the MAPE of CO concentration has the lowest values below 0.001%, and the other  
 466 species are in the range of 0-0.01%. Overall, the above time-series analysis verifies the  
 467 accuracy and stability of the modeling system on the MIPS platform.

468

469 **Figure 9.** Time series of MAEs, RMSEs and MAPEs for NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and  
 470 PSO<sub>4</sub> concentration in the 72h simulation. The yellow bar, the MAE. The red lines,  
 471 RMSE, the blue lines, MAPE.

472

473 In this study, the evaluation method proposed by Wang et al. (2021) was also used  
 474 to assess the scientific applicability of the model results on the MIPS platform. The  
 475 Root Mean Square Errors (RMSEs) for NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and PSO<sub>4</sub>  
 476 concentration between the MIPS and benchmark platform were computed, along with  
 477 the standard deviations (stds) used to describe the spatial variation of species, and the  
 478 ratio of RMSE to std, as shown in Table 6. The differences of the four species between  
 479 the two platforms are negligible compared to their own spatial variations. Therefore,  
 480 the results on the MIPS platform meet the accuracy requirements for research purpose.

481

482 **Table 6.** RMSE, std, RMSE/std for NO<sub>2</sub>, SO<sub>2</sub>, O<sub>3</sub>, CO, PNO<sub>3</sub> and PSO<sub>4</sub>.

	Differences in results	Spatial variation	RMSE/std
	RMSE	std	
NO <sub>2</sub>	$6.3 \times 10^{-7}$	0.01	$5.9 \times 10^{-5}$

<b>O<sub>3</sub></b>	$2.8 \times 10^{-7}$	0.01	$2.5 \times 10^{-5}$
<b>SO<sub>2</sub></b>	$6.3 \times 10^{-7}$	0.02	$3.9 \times 10^{-5}$
<b>CO</b>	$7.9 \times 10^{-6}$	0.30	$2.6 \times 10^{-5}$
<b>PNO<sub>3</sub></b>	$1.5 \times 10^{-3}$	3.8	$3.9 \times 10^{-4}$
<b>PSO<sub>4</sub></b>	$2.7 \times 10^{-4}$	3.9	$6.9 \times 10^{-5}$

483

484 In fact, the differences in model results cannot be completely eliminated, primarily  
485 due to the varying CPU architectures and compilers. In the practical applications,  
486 compared with the errors arising from the inherent uncertainties of the modeling system  
487 and the input data, the differences of model results between different platforms can even  
488 be considered negligible. The comprehensive analysis demonstrates that the results of  
489 the WRF-CAMx modeling system on the MIPS CPU platform are reasonable.

490

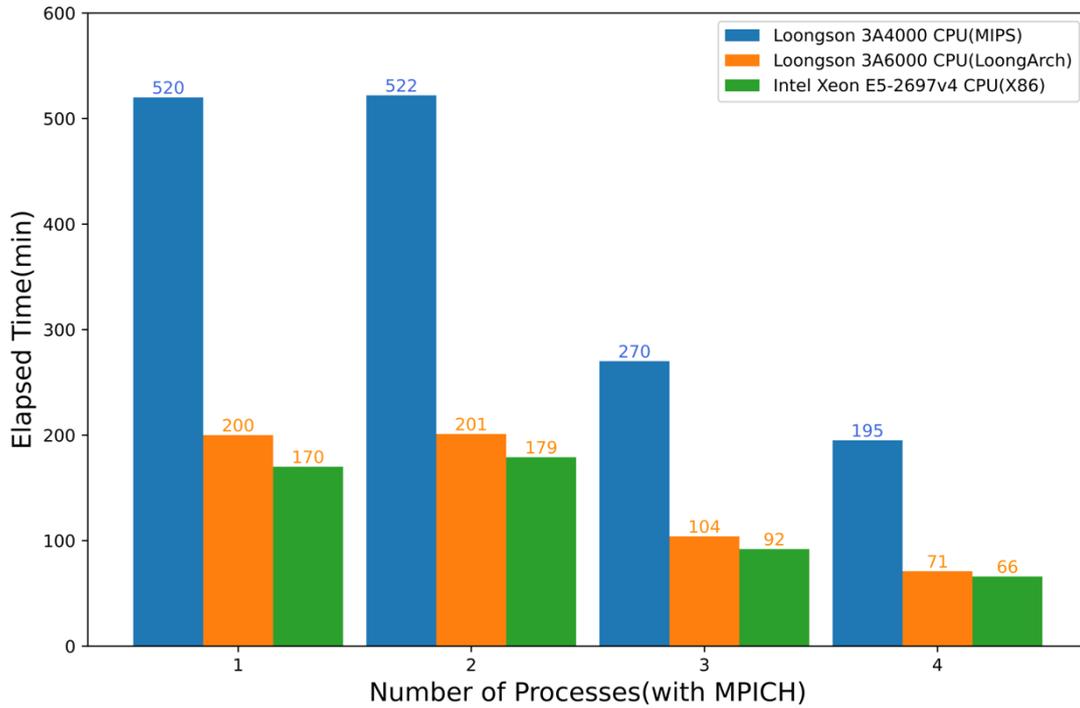

## 491 **5 The evaluation about computational performance**

492 Scientific computing involves a significant amount of floating-point operations,  
493 and the floating-point computational capability is a crucial indicator for CPU  
494 performance. In this study, the simulation case was configured to conduct parallel  
495 computing tests on the MIPS, LoongArch and benchmark platform. These tests  
496 included assessing the CPU's single-core performance with the non-parallel model and  
497 the platform's parallel performance with the parallel model using multiple processes.  
498 The time of CAMx model running simulation case for 24 hours in the modeling system  
499 are shown in Figure 9. From the figure, it can be observed that under single-core  
500 conditions, the computing capability of the MIPS platform for CAMx is approximately  
501 one-third of the X86 benchmark platform, and the LoongArch platform is slightly lower  
502 than the X86 benchmark platform.

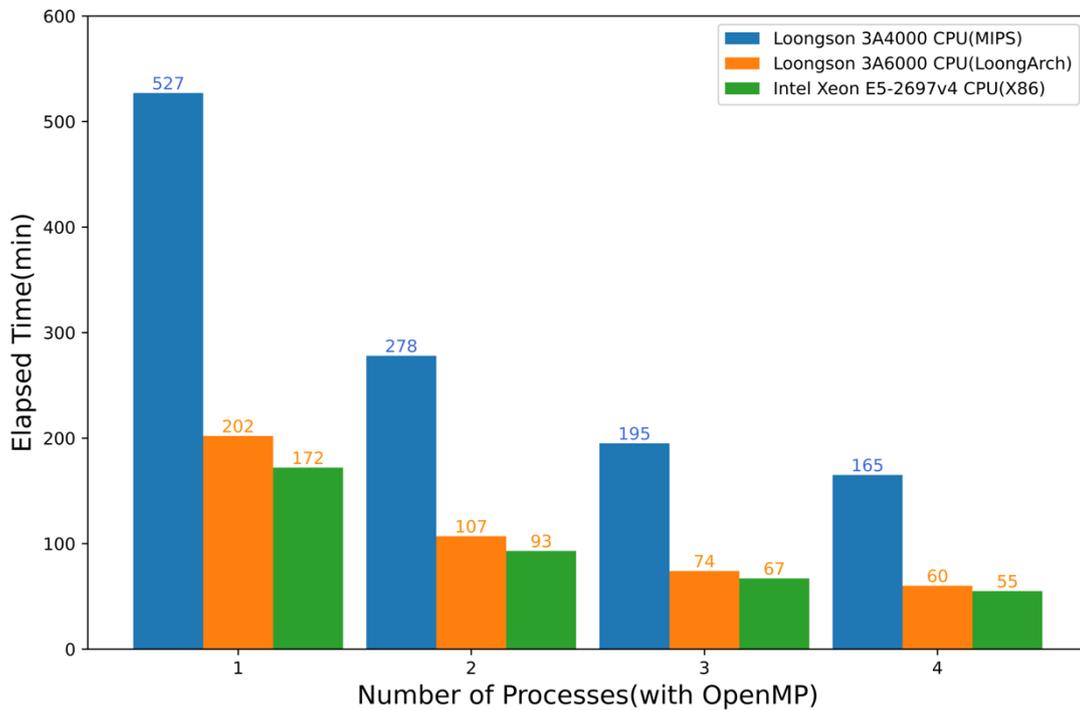

503 It's worth noting that the simulation time of the CAMx model for running with two  
504 processes in parallel and running in non-parallel remains approximately consistent.  
505 This is because the MPI used in CAMx is designed using a "master/slave" parallel  
506 processing approach, and a process is allocated for input/output and message  
507 communication during the runtime (Cao K et al., 2023). This process doesn't perform  
508 any simulation in the model. Therefore, the time required for parallelism of two

509 processes is comparable to the non-parallelism, and in some cases, it might even be  
510 slightly longer due to the overhead of MPI communication. Compared to non-parallel,  
511 the speedup of the MIPS platform with four-process parallelism using MPICH3 is  
512 approximately 2.8, while using OpenMP is about 2.9, and the speedup of the  
513 LoongArch platform with four-process parallelism using MPICH3 is approximately 2.8,  
514 while using OpenMP is about 2.9. For the X86 benchmark platform, running with four  
515 processes in parallel using MPICH3 has a speedup of approximately 2.7.

516 Additionally, the performance of the MIPS platform significantly decreases when  
517 the number of parallel processes exceeds 4. This is because the modeling system  
518 involves compute-intensive tasks. The Loongson 3A4000 CPU has four cores, and  
519 when the number of processes called by MPI matches the number of CPU cores, the  
520 CPU utilization can approach 100%. Further increasing the number of processes, the  
521 cores will compete for CPU resources, resulting in additional overhead and reduced  
522 computational efficiency. As for LoongArch platform, the performance slightly  
523 decreases when the number of parallel processes exceeds 4. The Loongson 3A6000  
524 CPU has four physical cores and eight logical cores, and when the number of processes  
525 called by MPI matches the number of physical cores, the computational load is evenly  
526 distributed across each core. Although the Loongson 3A6000 supports hyper-threading,  
527 further increasing the number of processes, CPU starts to schedule logical cores to  
528 allocate computational load. Thread scheduling will result in additional overhead and  
529 reduced computational efficiency. This explains why the elapsed time is slightly higher  
530 when CAMx running with 5 parallel processes compared to 4 parallel processes as  
531 shown in the section 2 of Supplementary Material.

532

533

534 **Figure 10.** Elapsed time of CAMx model running simulation case with MPICH and  
 535 OpenMP for 24 hours on the MIPS, LoongArch and benchmark platforms.

536

537 In the recent years, the Loongson CPUs have been continuously upgraded.  
 538 Compared to the previous generations of products, the performance of Loongson CPUs  
 539 has shown significant improvement. Wu et al. (2019) simulated a nested domain

540 covering Beijing for 48 hours using the MM5 model on the Loongson 3A quad-core  
541 CPU platform. The results showed that the computational capacity of the Loongson 3A  
542 platform for the MM5 model is approximately equivalent to around 1/12 of the Intel  
543 Core 2 Q8400 quad-core CPU, which was released in the same year. In the study of  
544 Luo et al. (2011), a comparison between Loongson 3A and Intel i5 was made by running  
545 NPB benchmark on each platform. The results shows that the performance of the 3A is  
546 nearly one-tenth of that of the i5. The rapid development of Loongson CPUs has  
547 provided a strong hardware foundation for the application of numerical simulation and  
548 scientific computing on MIPS and LoongArch architecture CPU platforms. Based on  
549 the performance evaluation of WRF-CAMx modeling system on Loongson 3A4000  
550 and Loongson 3A6000 platform, it could be found that the computing capability nearly  
551 tripled while maintaining similar power consumption. The adaptation and optimization  
552 of the models based on RISC CPUs will also be an important research direction in the  
553 future. Many factors influencing parallel performance, such as computing scale, I/O,  
554 multiprocessor, etc., will be considered to evaluate on platforms with stronger  
555 performance and more processors in the future.

556

## 557 **6 Conclusion**

558 This study describes the application of the WRF-CAMx model on the MIPS CPU  
559 platform. The platform used in this study is Loongson 3A4000 quad-core CPU with the  
560 main frequency of 1.8-2.0GHz, which can offer a peak operational speed of 128GFlops.  
561 It is equipped with the MIPS GNU compiler. The benchmark platform used the Intel  
562 Xeon E5-2697 v4 CPU along with the same version of X86 GNU compiler. Based on  
563 the characteristics of CPU architecture and compiler, this study has successfully  
564 completed the construction of runtime environment for the WRF-CAMx modeling  
565 system. The application of an air quality modelling system based on WRF-CAMx was  
566 successfully tested using a 72-hour simulation case in the Beijing-Tianjin-Hebei region.

567 The results showed that the spatial distribution of the meteorological variables and  
568 air pollutant species was nearly identical, with relative errors in the range of  $\pm 0.1\%$ .

569 Statistically, the maximum MAEs of major species ranged from  $10^{-3}$  to  $10^{-2}$  ppbv ( $\mu\text{g}$   
570  $\text{m}^{-3}$ ), the maximum RMSEs ranged from  $10^{-2}$  to  $10^{-1}$  ppbv ( $\mu\text{g} \text{m}^{-3}$ ), and the MAPEs  
571 remained within 0.5%, that the differences caused by the architectures and compilers  
572 were within a reasonable range. Simulating a 2h-case with four parallel processes using  
573 MPICH, CAMx takes about 15.2min on Loongson 3A4000 CPU and 4.8 min on Intel  
574 Xeon E5-2697 v4 CPU. In terms of single-core CPU performance, the single-core  
575 computing capability of Loongson 3A4000 CPU for the WRF-CAMx modeling system  
576 is about one-third of Intel Xeon E5-2697 v4 CPU.

577 Currently, Loongson Technology has focused on the LoongArch architecture and  
578 it has been used in the latest product. It is foreseeable that the LoongArch architecture  
579 will lead to more significant performance improvements. In the future, as the numerical  
580 models become more complex and computational scales become larger, more models  
581 will be tested on high-performance computing platforms equipped with the LoongArch  
582 architecture CPUs.

583

584 ***Code and data availability.*** The source codes of CAMx version 6.10 are available at  
585 <https://camx-wp.azurewebsites.net/download/source> (ENVIRON, 2023). The datasets  
586 related to this paper and the binary executable files of CAMx for MIPS and LoongArch  
587 CPUs are available online via ZENODO (<https://doi.org/10.5281/zenodo.10722127>).

588

589 ***Supplement.*** The supplement related to this article is available on-line.

590

591 ***Author contributions.*** ZB and QW conducted the simulation and prepared the materials.  
592 QW planned and organized the project. ZB and QW completed the porting and  
593 application of the model for MIPS and LoongArch CPUs. YS collected and prepared  
594 the emission data for the simulation. ZB, QW, KC, and HC participated in the  
595 discussion.

596

597 ***Acknowledgements.*** The National Key R&D Program of China (2020YFA0607804)  
598 and the Beijing Advanced Innovation Program for Land Surface funded this work. The

599 research is supported by the High Performance Scientific Computing Center (HSCC)  
600 of Beijing Normal University.
