11 **Abstract:** Scientific drilling in polar regions plays a crucial role in obtaining ice cores and using them
12 to understand climate change and to study the dynamics of the polar ice sheet and its impact on global
13 environmental changes (sea level, ocean current cycle, atmospheric circulation, etc.). Mechanical
14 rotary cutting is a widely used drilling method that drives the cutter to rotate to cut and drill through ice
15 layers. It is necessary to conduct in-depth research on the brittle fracture behavior of ice and
16 mechanical model, and analyze the factors and specific mechanisms (cutter's angle, rotation speed of
17 the drill bit, and cutting depth) affecting cutting force for the rational design of ice-core drill system,
18 improving the efficiency of ice-core drilling, and ensuring the drilling process smoothly. Therefore, in
19 this paper, the process of ice cutting was observed, the fracture mechanics characteristics of ice cutting
20 process was analyzed, the formation process of ice chips was divided into three stages, and the
21 mathematical model for the cutting force was established based on the observation results. It describes
22 the damage conditions of ice failure and points out the influencing factors and specific influencing laws
23 on cutting force. Furthermore, the cutting force generated under various experimental conditions was
24 tested. Based on typical real-time data curves of cutting force, the characteristics of cutting force were
25 analyzed during the cutting and drilling process. Based on the comparison results of the average cutting
26 force, the influence mechanism of various parameters on the cutting force is obtained. This proves the
27 correctness of the mathematical model of the cutting force and provides a theoretical reference for the
28 calculation of cutting force during ice cutting and drilling in polar regions.

29 **1. Introduction**

30 As the largest cold source on Earth, Polar ice sheets/glaciers are an important component of the
31 Earth's system related to the Earth's crust, glaciers, ice shelf, ocean, and atmosphere, it has a profound
32 impact on global changes such as climate change and sea level rise et al (Lin Yang et al., 2023). Many
33 scientific issues related to polar regions can be solved and validated by carrying out scientific drilling
34 in ice sheets and obtaining ice cores (S.H. Faria et al., 2014; P. Talalay et al., 2015; P.L. Cao et al l.,
35 2019). Mechanical rotary drills have been widely used in the field of polar ice core drilling (Ueda and
36 Garfield, 1968, 1969; Gundestrup et al., 1984; Kudryashov et al., 1994; Stanford, 1992; Wumkes, 1994;
37 Shturmakov et al., 2007). The process of ice core drilling mainly consists of three steps: Cutting and
38 drilling of the ice sheet, removal and transport of the ice chips generated at the hole bottom, and the
39 collection of ice core and chips precipitation (Litvinenko VS and Nikolay I Vasiliev et al., 2014). These
40 three steps are interrelated, and all of them have significant effects on the process of drilling. The
41 cutting and drilling of the ice sheet generate a cutting force, which not only affects the selection of the
42 motor system of the drill but also the design of the anti-torsion system, and even determines the success
43 or failure of the cutting and drilling of the ice sheet. By conducting in-depth research on the fracture
44 mechanics characteristics of solid ice, establishing a mechanical model for ice cutting, and determining
45 the factors and specific mechanisms affecting cutting force, it can contribute to the rational design of
46 the drilling tool system, the improvement of drilling efficiency, and ensure the smooth progress of
47 drilling.

48 During ice core drilling, ice cutting is periodically carried out. At first, the moving cutters cut into
49 the ice and compress it. When the level of stress near the edge of the cutter exceeds the cutting point, a
50 crack is formed in the direction from the edge to the surface. This means that the horizontal force of
51 cutting, called P_x , creates a repeated series of breaks, and its value is considered to be the mean force
52 over the cutting length. Griffith (1920) assumed that when the energy of elastic strain exceeds the
53 surface energy, the existing micro-crack starts to extend like an avalanche, and the materials break.
54 Mellor and Sellman (1976) suggested that cutting force P_x can be calculated by using specific energy
55 E_S (N/m^2), which is the energy consumed per unit of cutting volume:

$$56 \quad P_x = bhE_S \quad (1)$$

57 where b is the width of the cutter; h is the depth of cut.

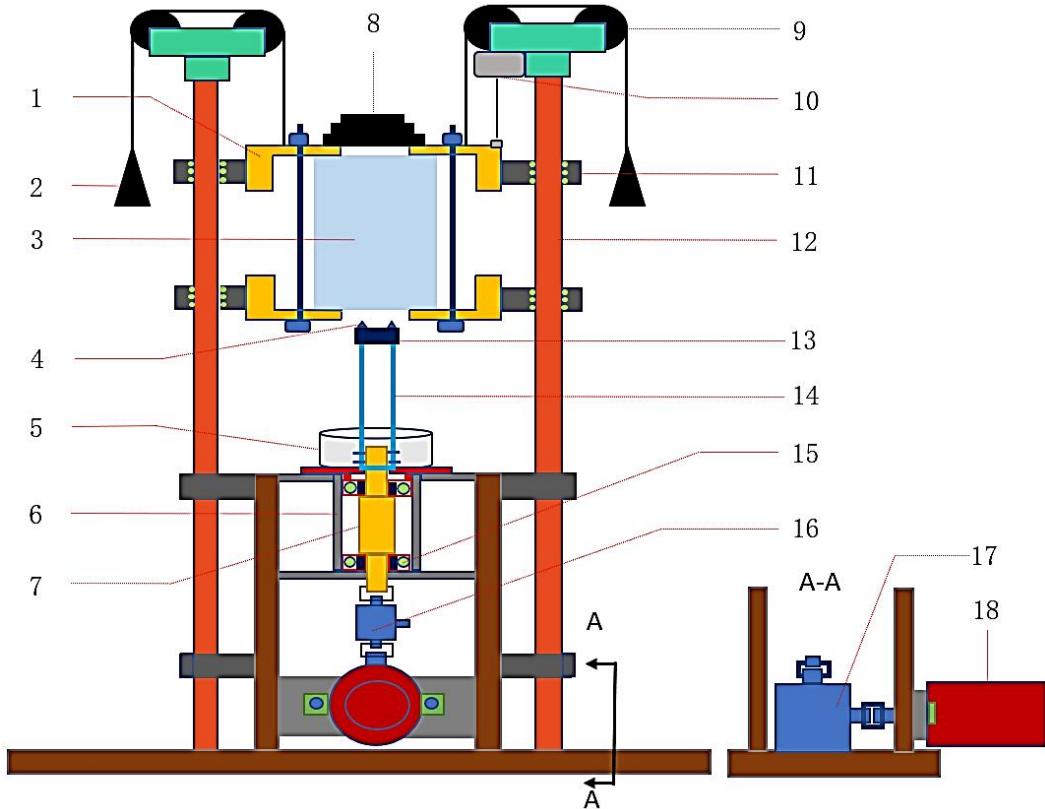

58 Using the formula (1) to calculate cutting force is difficult because specific energy is a vague
59 concept. The formula ignores the influence of the structure of the cutter on the cutting force and lacks a
60 certain degree of practicality. Due to the difficulty of conducting strict theoretical methods for the
61 design of rock-cutting machines, many of the same experimental methods were developed by Mellor
62 (1981). Maeno (1988) assumed that in any deformation process caused by compression, tension,
63 bending, or cutting, the mechanics of ice failure are determined by the processes of inter/intragrain
64 sliding. Taking the ideal monocrystal of ice, the theoretical stress needed for the formation of sliding
65 zones is near 100 MPa, but for real ice, it does not exceed 0.1– 0.5 MPa (Lavrov, 1969). The
66 contradiction is explained by the disposition theory. According to this theory, the deformation of the
67 ice is determined by the defects which already exist in the ice crystal. The internal defects gradually
68 expand under the action of external forces, the ice destruction occurs. Due to the non-uniformity, hard
69 brittle, and the factors that affect cutting resistance are complex, most studies on solid ice are
70 conducted to investigate the influence of a certain variable on cutting resistance (Chiaia, 2008; S. Hell
71 et al., 2014; A. Chao Correas et al., 2022). The in-depth study of the cutting properties of solid ice was
72 rarely reported.

73 In this paper, images of the cutting and drilling process of the ice under various experimental
74 conditions were captured, the fracture mechanics characteristics of the ice cutting process were
75 analyzed, and the formation process of ice chips was clear and divided into three stages. Based on the
76 result, a mechanics and mathematical model of ice cutting was built, and the influencing factors and
77 specific influencing laws on cutting force were analyzed. Finally, the influencing factors and laws were
78 verified through experimental tests. Which provides a theoretical reference for the calculation of
79 cutting force during ice cutting and drilling.

80 **2. Observation of ice fissure propagation in the process of ice cutting for ice-core drilling**

81 **2.1. Test stand design for study on ice cutting process**

82 To observe the cutting and drilling process of the ice under various experimental conditions, an ice
83 cutting and drilling simulation test stand has been designed (Fig. 1).

84

85 **Figure 1.** Schematic diagram of the experimental platform: 1-ice box; 2-balance weight 1; 3-ice block; 4-cutter;
 86 5-ice chips collector; 6-cup set; 7-stepped shaft; 8-dead weight; 9-fixed pulley; 10-draw-wire displacement sensor;
 87 11-slider; 12- slide rail; 13-drill bit; 14- drill pipe; 15- bearing; 16-torque sensor; 17- directional converter;
 88 18-servo motor

89 To ensure the ice cutting and drilling proceed smoothly and the WOB is constant during the drilling
 90 process, the drilling direction is inverted upward. Therefore, the ice chips generated in the drilling
 91 process directly fall into the ice chips collector due to gravity, there will be no adhesion or blockage on
 92 the drill bit. During the experimental process, the ice block and ice box can slide nearly frictionless as
 93 they are connected to two parallel slide rails through four sliders, and the slider is equipped with rolling
 94 balls inside to ensure that the slider slides almost frictionless on the slide rail. So, during the drilling
 95 process, constant drilling pressure can be ensured, and multiple drilling pressure tests can be achieved
 96 by increasing or decreasing balance weight and dead weight. The drill pipe, drill bit, and cutters are
 97 driven to rotate by the servo motor system, and its rotation speed can be adjusted arbitrarily between
 98 0-1000rpm. In this way, the adjustment of the rotation speed of the drill bit is achieved. The cutter
 99 equipped in the experimental test stand can be replaced arbitrarily according to the experimental

100 requirements, therefore, it is possible to conduct cutting and drilling tests on cutters with various
101 structures.

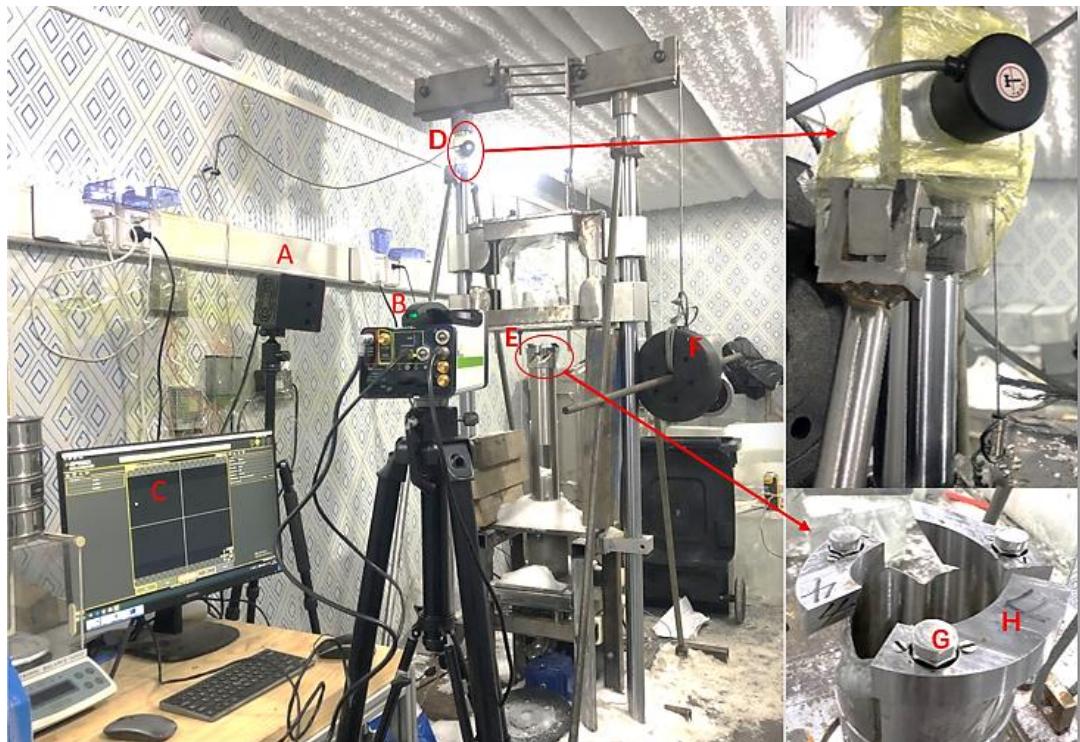

102 During the experiment, the torque generated by driving the rotation of drill pipes, step shafts, and
103 other components, as well as the cutting torque generated by ice cutting is measured by the torque
104 sensor. Before conducting the cutting and drilling experiment, adjust the rotation speed of the drill bit
105 to the rotation speed for the next experiment, and let the drill bit and other components blank run. After
106 the torque measured by the torque sensor stabilizes, the torque is recorded as T_1 . Next, perform cutting
107 and drilling. After the cutting and drilling process stabilizes, the recording of cutting torque begins.
108 after the drilling process, the average cutting torque during this period is recorded as T_2 . So, the torque
109 for ice blocks cutting T_c can be calculated according to the following formula (2).

110
$$T_c = T_2 - T_1 \quad (2)$$

111 The drilling depth and time are measured by the Draw-wire displacement sensor. The formation
112 process of ice chips is captured by a high-speed camera.

113 **2.2. Test stand building and observation of ice fissure propagation during ice-core drilling testing**

114 Based on the above working principle, the ice core drilling test stand has been established (Fig. 2).

116 **Figure 2.** Test stand: A-light source; B-high speed camera; C-image display computer; D-draw-wire
117 displacement sensor; E-drill bit; F-counterweight block; G-drill bit shoe; H-cutter

118 The specific parameters of the main equipment in the test stand are shown in Table 1.

119 **Table 1.** Main parameters of equipment

equipment and sensor	Model	Main parameters
Driver	3DM2080-DSP	Drive voltage: 130-220VAC Pulse mode: Mono pulse Adjustment range: 0-1000rpm
Servo motor system	130BYG350D	Maximum output torque: 60N.M Step angle: 1.2° Rated voltage and current: 220V and 8.5A
Pulse generator	CS10-3	Output mode: Steering + pulse Adjustment range: 0-1000rpm Output signal voltage: 5V; Power range:9-30V
Torque sensor	LLBLS-I	Measuring range: 60N.M; Overall accuracy:0.3% Maximum speed: 6000rpm
Draw-wire displacement sensor	MPS-M	Measuring distance:0-1500mm Resolving power:0.01mm; Pulling force of stay wire:4N
Slide rail and slider system	Ø50; SK50	Friction coefficient: 0.0010-0.0015
High-speed camera	Ispeed-7	Technology: CMOS active pixel Resolution: 2048×1536 Frames per second: 1000000fps Shutter: 1us Lens options: F mount/G mount/C mount

120 Before the experiment, the cutters (Fig.2.H) made from tool steel (W18Cr4V) shall be installed on
121 the drill bit (Fig.2.E) through bolts and pins (Fig.2.H) that also serve as the shoes with adjustable height.
122 The height of the bolts is lower than the height of the cutter's tip when the ice block slides into contact
123 with the shoes, the cutters have been cut into the ice block at the designed depth. Thus, the cutting and
124 drilling at the designed cutting depth is realized and the cutting depth has been accurately controlled.

125 Aiming the high-speed camera (Fig.2.B) at the cutting edge of the cutter, adjusting the frame number
126 of the high-speed camera to 100,000, meanwhile, supplementing the light on the object with the light
127 source (Fig.2.A), until the image displayed in the computer (Fig.2.C) is clear. After the experiment, the
128 images of the formation process of ice chips are captured and saved in a high-speed camera. The
129 observation experiment of the cutting and drilling process is conducted under various experimental

130 conditions (multiple cutter angles, cutting depths, and rotation speed of drill bit). The specific
 131 parameters of experimental conditions are shown in Table 2. The cutter used in the experimental
 132 process are processed with wire cut technology. Before the experimental, to prevent the impact of
 133 surface burrs, slag, and surface roughness on the test results, sandpapers with 1000 mesh, 1500 mesh,
 134 and 2000 mesh were selected respectively to manually polish the surface of the cutter until it was
 135 smooth. After each test, the surface and cutting edge of the cutter are observed, if there is wear or
 136 damage, the cutter is polished or replaced directly. The cutters- tested in the experiment are shown in
 137 Fig. 3.
 138

Table 2. The specific parameters of experimental conditions

Structure of cutter						
Width (mm)	Rake angle (°)	Relief angle (°)	Cutting depth (mm)	Rotation speed (rpm)	Ice sample dimension (mm)	Ice core diameter (mm)
	20	5	1	50		
25	30	10	2	100	~250×250×450	60
	40	15	3	150		

139
 140 **Figure 3.** Multi-group structure cutters
 141 This study mainly focuses on the establishment of mechanical model during the ice cutting and
 142 drilling process. And, studies have shown that the crystal orientation, the crystal size and the density of
 143 ice samples in NGRIP boreholes in Greenland are similar to naturally formed and artificially frozen ice
 144 samples (Center for Ice and Climate, 2023). Moreover, many scholars have conducted experiments on
 145 artificially prepared or naturally formed ice samples, and have ultimately obtained convincing
 146 experimental data and conclusions, providing valuable references for research in the polar field
 147 (Talalay, 2003; Hong et al.,2015; Wang et al, 2024). In order to better observe the formation process of

148 ice chip, at present stage, this study selected transparent ice and explored the fracture process and
149 cutting force generated by this type of ice. The ice with variety properties belongs to brittle materials,
150 and there will be similarities in the fracture process. In the future, the cutting and drilling experiments
151 with different ice sample properties to explores the effect of ice properties against the cutting force will
152 be carried out. The ice blocks used in this experiment are frozen by an ice-making machine (Fig.4),
153 which can produce transparent ice samples without bubbles. Then, we divided these blocks into
154 experimental ice blocks with uniform dimensions (Fig.5) of $\sim 250 \times 250 \times 450$ mm. and all tests were
155 carried out in the refrigerated container with a constant temperature of -15°C .

156

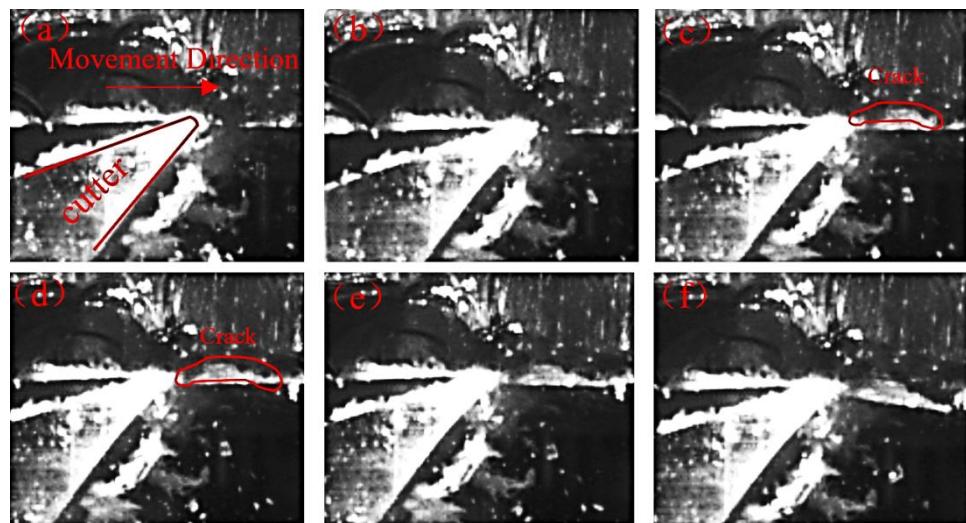

157 **Figure 4.** Ice-making machine

Figure 5. Experimental ice samples

158 **3. Analysis of characteristics of ice fracture mechanics in the process of ice cutting**

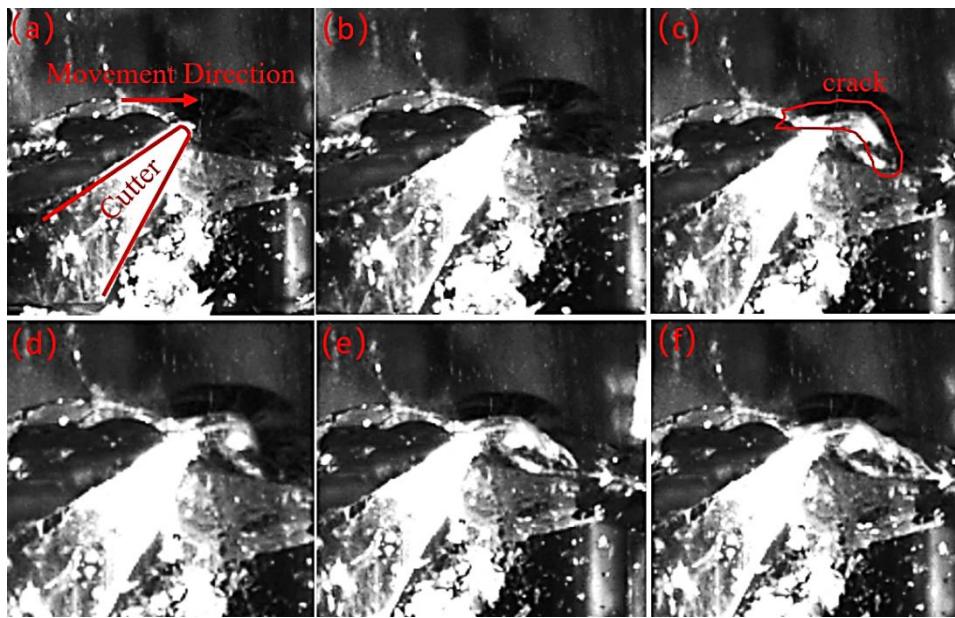

159 It is preliminary observed after the mechanical testing of ice under the special experimental
160 condition. The actual ice-cutting process captured by a high-speed camera is shown in Fig. 6.

161

162 A (rake angle is 40° , relief angle is 15° , cutting depth is 1 mm and the rotation speed of the drill bit is

163 100 rpm)

164

165 B (rake angle is 30° , relief angle is 25° , cutting depth is 2 mm and the rotation speed of the drill bit is

166 100 rpm)

167 **Figure 6.** Cutting process captured by high-speed video camera

168 Compared with the cutting and drilling process at a cutting depth of 1mm, when cutting and drilling
169 at a cutting depth of 2mm, the depth of the cutter inserted into the ice sample increases resulting in
170 more small particle ice chips. The particle size of the ice chips formed by major fracture increases, and
171 the surface after cutting becomes more uneven.

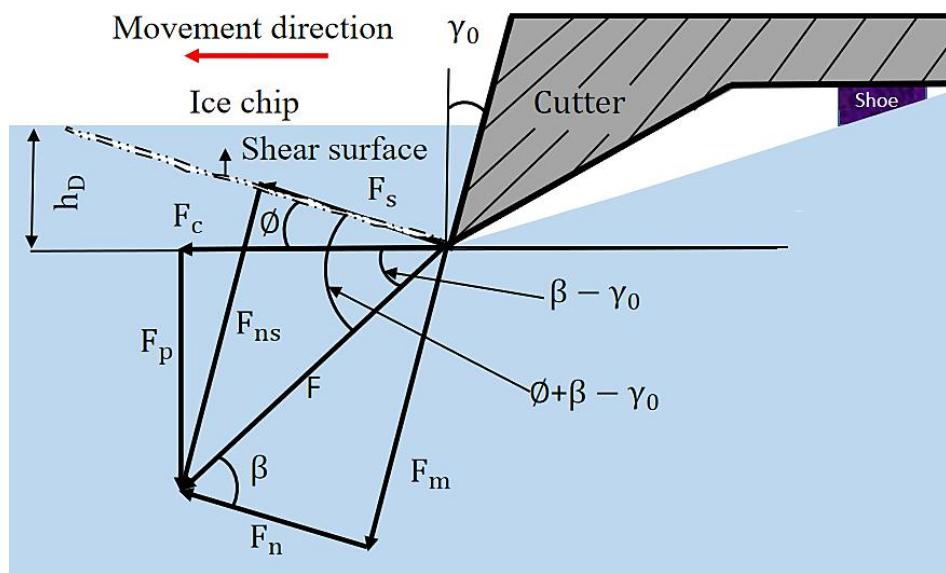

172 Under various experimental conditions, the ice cutting process is similar. In the cutting process, the
173 cutting of the ice is constantly repeated, the main damaged form of ice is a brittle fracture, the chips
174 show wedge block with no significantly deform, and wedge-shaped ice chips with different particle
175 sizes are constantly formed under variety experimental conditions. The formation process of a single
176 large particle of ice chips can be divided into three stages. In the first stage, the cutter invades the ice,
177 and the ice is compressed by the rake and relief surfaces of the cutter, resulting in ice crushing and
178 smaller ice chip formation (Fig. 6. a, b). In the second stage, with the rotation of the drill bit, cracks
179 appeared in the ice, and the cracks began to expand along a direction that approximately presented an
180 angle of 45° with the horizontal direction (Fig. 6. c, d). However, there were no gaps or separations
181 between the ice and cutters on both sides of the cracks. In the third stage, the cutter moved forward, the

182 crack expanded to form ice chips with large particle size that slid forward, and finally detached from
 183 the ice. At the same time, ice chips with small particle sizes were also generated on the sliding surface
 184 (Fig. 6. e, f).

185 **4. Study on a mechanical model of ice cutting process**

186 **4.1. Mechanical model building based on the characteristics of ice fracture mechanics**

187 According to the observation results of the ice cutting, it can be considered that the damage of the ice
 188 is the result of shear slip failure caused by the compression effect of the cutter. In this process, the force
 189 exerted on the ice chips mainly includes the squeezing force F_n towards the ice, and along the normal
 190 direction of the cutter's rake face. The frictional force F_m exerted by the cutter when the ice chips
 191 flow out; At the same time, the shear surface of the ice will also be subjected to normal pressure F_{ns}
 192 and shear force F_s . Before the cutting of the ice, these two pairs of forces are in equilibrium. The
 193 relationships between these forces are analyzed in front of the cutting edge (Fig. 7).

194

195 **Figure 7. Relationship between force and angle**

196 Where F is the combined force of F_m and F_n , ϕ is the shear angle, β (Friction angle) is the angle
 197 between F_n and F , γ_0 is the rake angle of the cutter, F_p is the component force perpendicular to the
 198 movement direction of the cutter, which is applied to the cutter and mainly provided by the weight on
 199 drill bit during the ice layer cutting and drilling, causing the cutter to cut into the ice to a certain depth.
 200 During the cutting and drilling process, the cutter comes into contact with the ice sample before the
 201 shoes. Only when the cutter is inserted into the ice layer with designed cutting depth, the shoes will

202 fully contact the bottom of the borehole. Prior to this, there will be continuous F_p on the cutter. As the
 203 drill bit rotates, the cutter always inserts the ice sample before the shoe, and the F_p on the cutter will
 204 continue to exist. Where F_c is the component force acting on the ice layer, and during the ice layer
 205 cutting and drilling process, this force is mainly provided by the motor, which is called the cutting
 206 force. h_D is the cutting thickness. If the cutting width is represented by b_D , The cutting width
 207 represents the width of the annular gap between the ice core and the hole wall in the process of ice
 208 drilling (cutting width, width of the cutter), The area of the nominal cross-section of the cutting layer is
 209 represented by A_D ($A_D = h_D b_D$), The area of shear surface is represented by A_s ($A_s = A_D / \sin\theta$), the
 210 shear stress on the shear plane is represented by τ , then

$$211 \quad F_s = \tau A_s = \frac{\tau A_D}{\sin\theta} \quad (3)$$

212 According to Fig. 7, it can be concluded that:

$$213 \quad F_s = F \cos(\theta + \beta - \gamma_0) \quad (4)$$

214 According to the relationship between various forces, it can be concluded that:

$$215 \quad F = \frac{F_s}{\cos(\theta + \beta - \gamma_0)} = \frac{\tau A_D}{\sin\theta \cos(\theta + \beta - \gamma_0)} \quad (5)$$

$$216 \quad F_p = F \sin(\beta - \gamma_0) = \frac{\tau A_D \sin(\beta - \gamma_0)}{\sin\theta \cos(\theta + \beta - \gamma_0)} \quad (6)$$

$$217 \quad F_c = F \cos(\beta - \gamma_0) = \frac{\tau A_D \cos(\beta - \gamma_0)}{\sin\theta \cos(\theta + \beta - \gamma_0)} \quad (7)$$

218 4.2. Analysis of factors influencing cutting forces via the mechanical model

219 According to Fig. 7, there is no shear stress in the plane perpendicular to the combined force F , so
 220 the main stress is completely determined by the F . The material is in the state of plane stress, and the
 221 included angle between the direction of the maximum shear stress and the direction of the maximum
 222 principal stress is 45° , the included angle between the maximum principal stress and the F is 45° , then
 223 there is:

$$224 \quad \theta + \beta - \gamma_0 = \frac{\pi}{4} \quad (8)$$

225 So:

$$226 \quad \theta = \frac{\pi}{4} - \beta + \gamma_0 \quad (9)$$

227 The shear angle θ is affected by the rake angle of the cutter γ_0 and friction angle β . As the rake
 228 angle of the cutter γ_0 increases, the shear angle θ increases; as the friction angle β increases, θ
 229 decreases.

230 The area of the nominal cross-section of the cutting layer is represented by A_D ($A_D = h_D b_D$), The
 231 area of the shear surface is represented by A_s ($A_s = A_D / \sin\phi$), the shear stress on the shear plane is
 232 represented by τ , then, according to equation (5) and the relationship between the nominal
 233 cross-section and the shear plane, it can be obtained that:

$$234 \quad F_c = \frac{\tau A_D \cos(\beta - \gamma_0)}{\sin\phi \cos(\phi + \beta - \gamma_0)} \quad (10)$$

235 When the ice is about to break, the shear stress on the shear plane reaches its maximum value. This
 236 value is determined by the properties of the ice and will not change as the drilling conditions. Therefore,
 237 the cutting force is influenced by the cutting width of the cutter and the cutting depth. The cutting force
 238 shows a linear increasing trend with the increase of the cutting width and the cutting depth. In addition,
 239 the cutting force is also affected by the shear angle ϕ 、friction angle β , and cutter's rake angle γ_0 . The
 240 friction angle β is a certain value as the properties of the ice and cutter's material. The shear angle ϕ is
 241 determined by the friction angle and the cutter's rake angle as shown in formula (9). Substituting
 242 equation (9) into (10) and solving for the combined cutting force F_c , the following equation can be
 243 given:

$$244 \quad F_c = \frac{\tau h_D b_D \cos(\beta - \gamma_0)}{\sin(\frac{\pi}{4} - \beta + \gamma_0) \cos(\frac{\pi}{4})} \quad (11)$$

245 After simplifying the above equation, it can be obtained that:

$$246 \quad F_c = \frac{2\tau h_D b_D}{1 - \tan(\beta - \gamma_0)} \quad (12)$$

247 It can be seen from the formula (12) that the factors affecting the cutting force mainly consist of four
 248 sides: The first aspect, it related to the shear strength of the ice, with the increase of shear strength, the
 249 cutting force increases gradually. The second aspect, it influenced by the cutting depth, with the
 250 increase of cutting depth, the cutting force increases gradually. The third aspect, it affected by the
 251 cutting width, with the increase of cutting width, the cutting force increases gradually. Finally, the rake
 252 angle of the cutter also has an impact on the cutting force. Formula (12) shows that: within the $\beta -$
 253 $\gamma_0 \leq \frac{\pi}{2}$ range, as the rake angle of the cutter γ_0 increases, $\beta - \gamma_0$ gradually decreases, and the
 254 $\tan(\beta - \gamma_0)$ decreases, $1 - \tan(\beta - \gamma_0)$ increases, F_c decreases.

255 **5. Test on the characteristics of cutting force and its influencing factors for verifying the**
 256 **mechanical model**

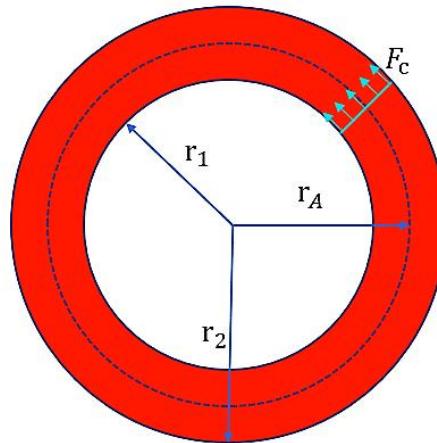

257 **5.1 Analysis of the characteristics of cutting force**

258 To verify the theoretical analysis results of the factors affecting cutting force, the cutting torque
259 collected by the torque sensor under various cutter angles, rotation speed of the drill bit, and cutting
260 depth conditions were measured.

261 After the experiment, the torque for ice cutting and drilling can be obtained through formula (2). The
262 schematic diagram of the torque and cutting force generated during the ice cutting drilling process is
263 shown in Figure 8, The relationship between the cutting force F_c generated by cutting the area of the
264 circular ring and the torque T_c measured by the torque sensor is as follow.

265
$$T_c = F_c r_A \quad (13)$$

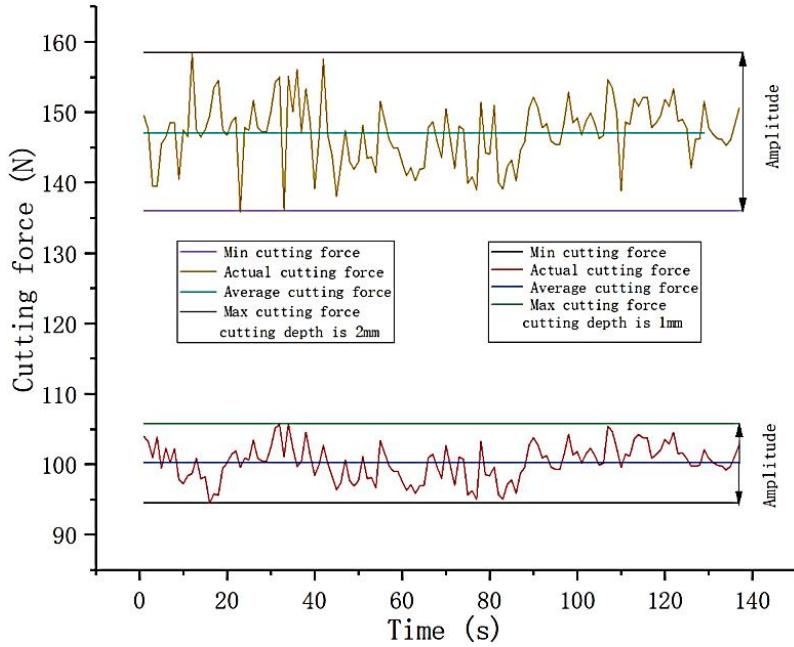

266 Where r_A is the average radius of the circular ring.

267

268 **Figure 8.** The schematic diagram of the torque and cutting force

269 By processing the data collected by the torque sensor, the cutting force generated by one cutter
270 during the ice block cutting and drilling is obtained. The typical cutting force trace generated during the
271 ice cutting process is shown in Fig. 9.

272

273 **Figure 9.** Typical cutting force trace (Cutting depth is 1 mm and 2 mm; Rotation speed of drill bit is 50rpm; Rake
274 angle is 30°; Relief angle is 5°)

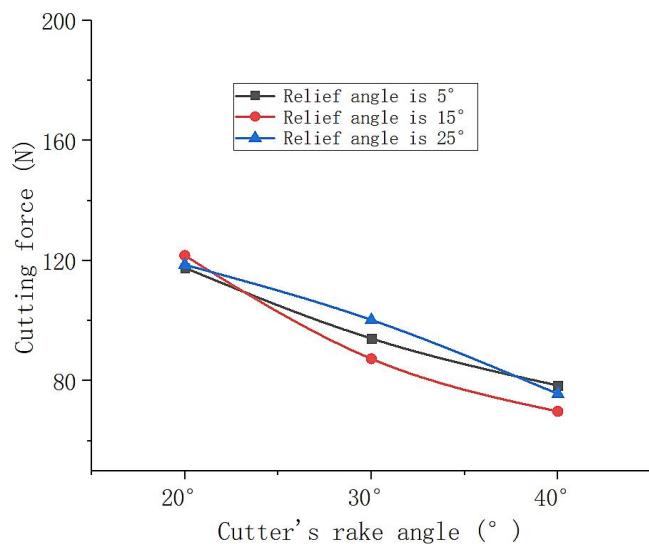

275 Fig. 9 shows the cutting force trace generated during two cutting and drilling process, which were
276 carried out under the same conditions except for cutting depth, both cutting force traces oscillate at a
277 certain frequency within a certain range, and the oscillation consists primarily of two frequencies, in
278 addition the oscillation frequencies of two cutting force trace are similar. The higher frequency is
279 related to the resolution of the sensor. The sensor outputs data at a certain interval during the recording
280 process, the output data is not continuous, resulting in fluctuations in the trace. The lower frequency is
281 related to the formation of large particle ice chips. Unlike ductile materials, where the chips produced
282 by a shearing action are continuous and the forces appeared relatively constant, chips from brittle
283 materials are produced by a repeated series of breaks. When the cutter is pressed into the ice, the
284 cutting force begins to rise and elastic energy is stored in the cutter assembly, some of the energy is
285 expended in local crushing, the ice layer undergoes shear-slip deformation. As the cutting force reaches
286 a magnitude necessary to induce a major fracture, a crack propagates into the ice, releasing the cutter
287 elastic energy and dislodging a major chip, the force than suddenly decreases. Therefore, during the
288 cutting and drilling process in the ice layer, the cutting force trace exhibits an oscillating state, the
289 amplitude of the oscillation is related to the cutting depth. During the process of the cutting depth
290 increase, the degree of rapid increase and decrease in cutting force will be more severe. As show in Fig.

291 9, when drilling with a cutting depth of 2 mm, the oscillation amplitude of cutting force is greater than
292 that of drilling with a cutting depth of 1 mm.

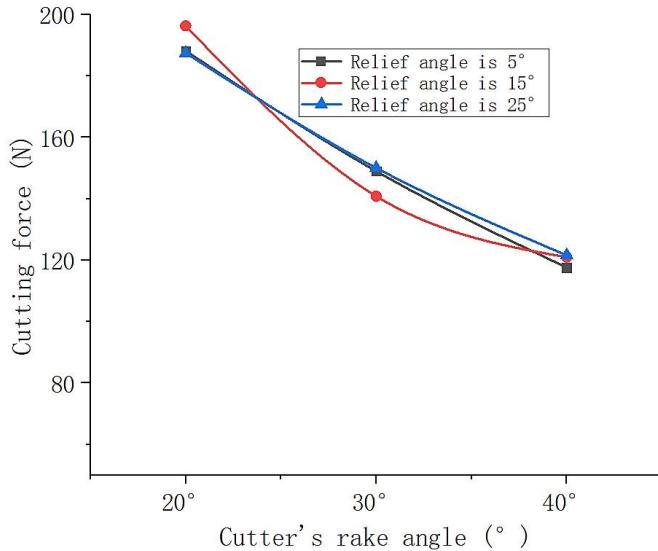

293 As the cutting depth increases, the degree of crack propagation into the ice will also increase. When
294 the crack extends into the ice core, it will cause a decrease in the surface quality of the ice core. It is
295 necessary to control the cutting depth reasonably during the cutting process to ensure the quality of the
296 ice core. Moreover, the study results on mechanical models of ice cutting process indicated that:
297 “within the range of $\beta - \gamma_0 \leq \frac{\pi}{2}$, the cutting force gradually decreases with the increase of the rake
298 angle”. The rake angle can be appropriately increases within this range to reduce the oscillation.

299 **5.2. Test of the factors influencing cutting force**

300 After the cutting and drilling experiments, the average cutting force was obtained under each
301 experimental condition. Plots of the average cutting force versus the cutter's rake angle are shown in
302 Fig. 10.

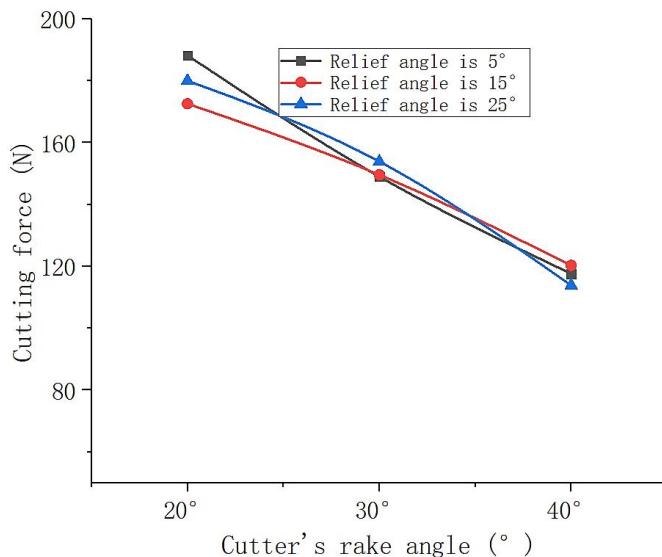

303
304 (a) The cutting depth is 1 mm, and the rotation speed of the drill bit is 100rpm

305

306

(b) The cutting depth is 2 mm, and the rotation speed of the drill bit is 100rpm

308

(c) The cutting depth is 2 mm, and the rotation speed of the drill bit is 50rpm

309 **Figure 10.** Cutting force versus cutter's rake angle

310 As shown in Fig. 10, when the cutting depth is 2mm, the rotation speed of the drill bit is 100 rpm,
 311 and the rake angle of the cutter is 20 °, the cutting force reaches the maximum value of 196.3451N.
 312 When the cutting depth is 1mm, the rotation speed of the drill bit is 100 rpm, and the rake angle of the
 313 cutter is 40 °, the cutting force reaches the minimum value of 69.83529N. The cutting force varies
 314 within this range under the other experimental conditions. That is, under various cutting depths and
 315 drill speed conditions, the cutting force gradually decreases with the increase of the cutter's rake angle.

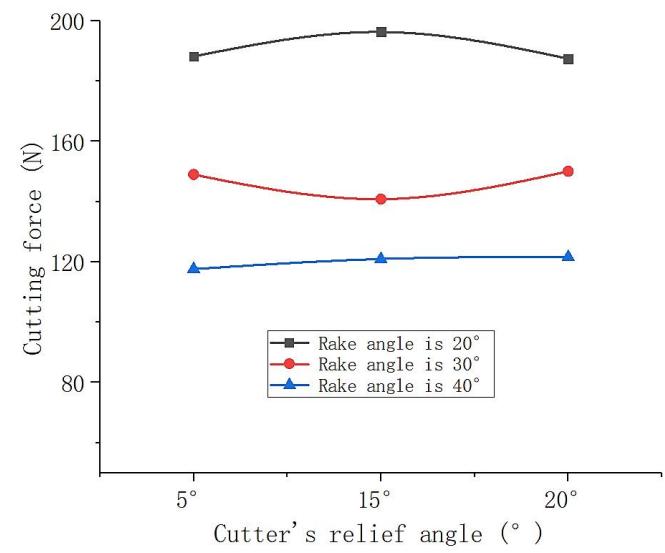

316 Plots of the average cutting force versus the cutter's relief angle are shown in Fig. 11.

317

318

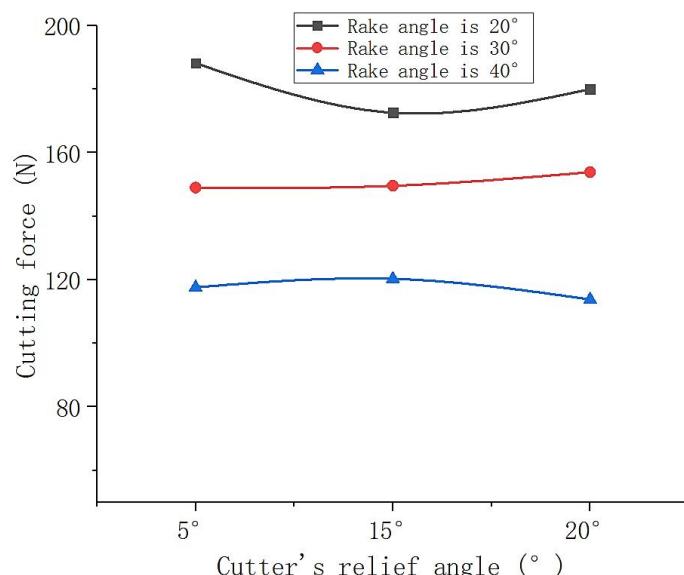

(a) The cutting depth is 1 mm, and the rotation speed of the drill bit is 100rpm

319

320

(b) The cutting depth is 2 mm, and the rotation speed of the drill bit is 100rpm

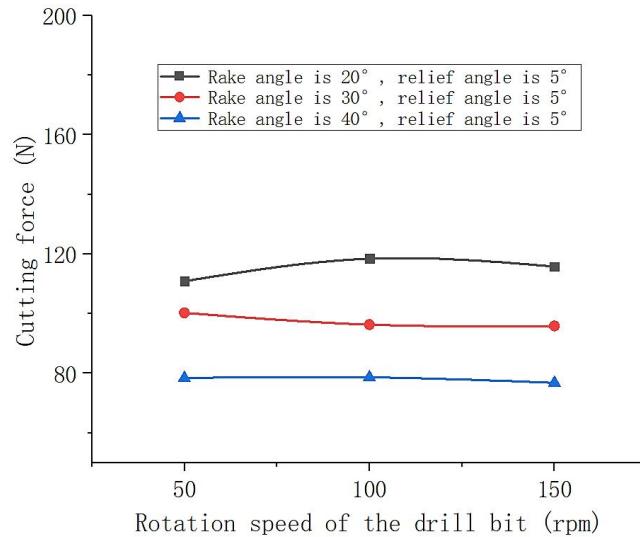

321

322 (c) The cutting depth is 2 mm, and the rotation speed of the drill bit is 50rpm

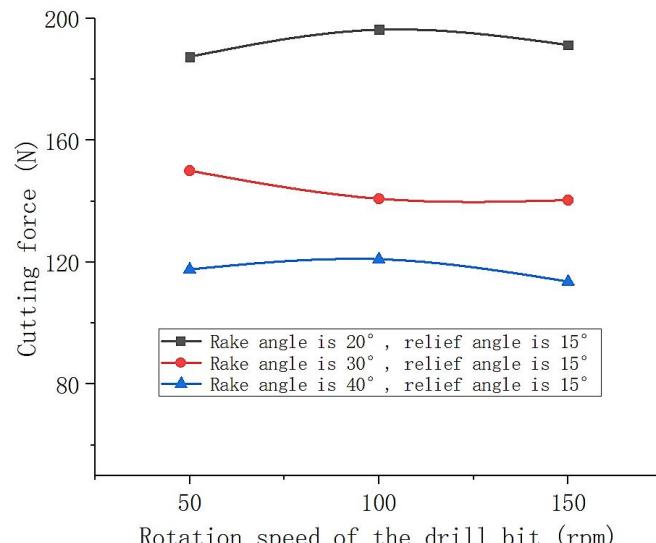

323 **Figure 11.** Cutting force versus cutter's relief angle

324 Under various experimental conditions, the relief angle of the cutter changes, and the cutting force
325 only changes slightly. Moreover, with the change of the relief angle of the cutter, the cutting force does
326 not show a clear and consistent change pattern. Therefore, it can be inferred that the relief angle of the
327 cutter has no clear effect on the cutting force.

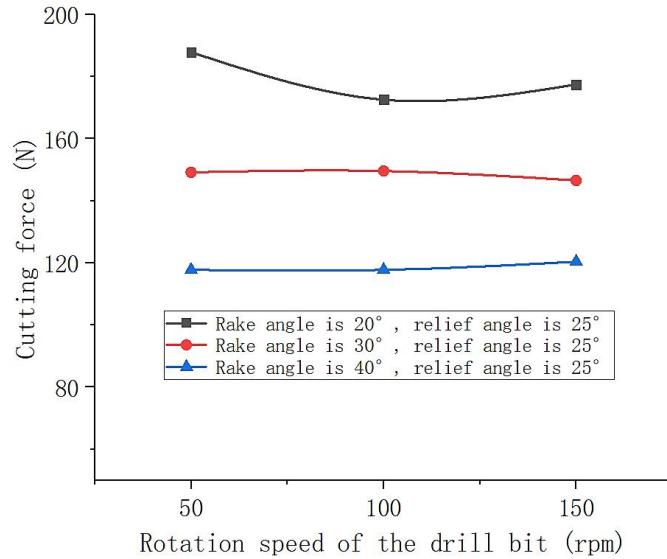

328 Plots of the average cutting force versus the rotation speed of the drill bit are shown in Fig. 12.

329 (a) The cutting depth is 1mm

330 (b) The cutting depth is 2mm

333

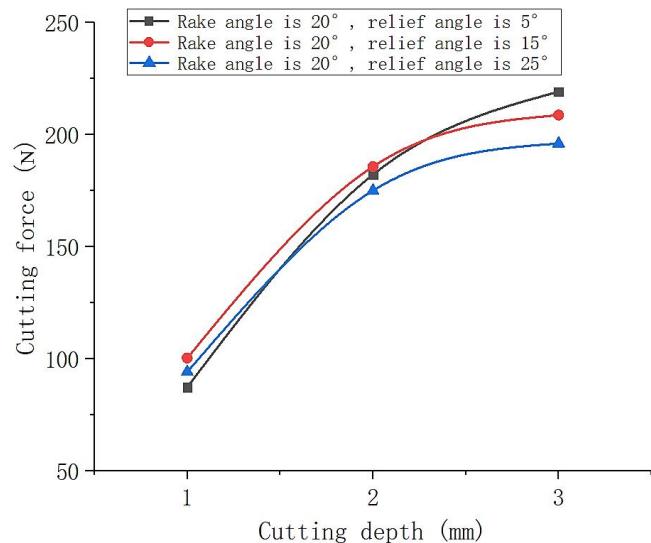

334

(c) The cutting depth is 2mm

335 **Figure 12.** Cutting force versus rotation speed of the drill bit

336 Under various experimental conditions, there is only a slight change in cutting force during the process of the
 337 rotation speed changing, and there is no clear pattern of change. The rotation speed of the drill bit does not affect
 338 the cutting force.

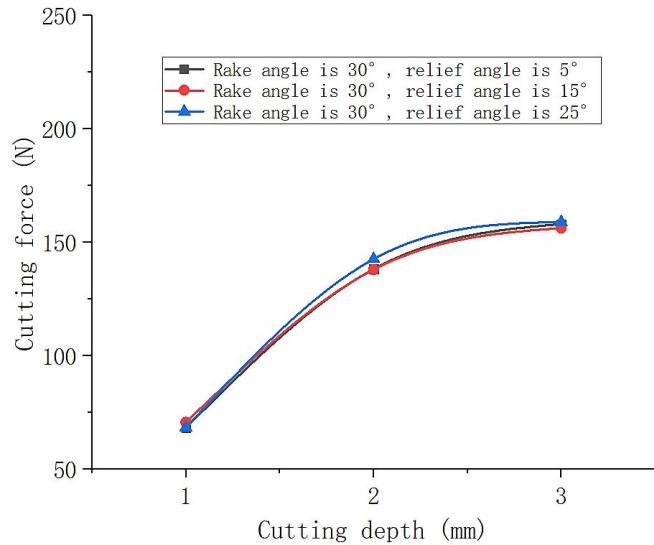

339 Plots of the average cutting force versus cutting depth are shown in Fig. 13.

340

341

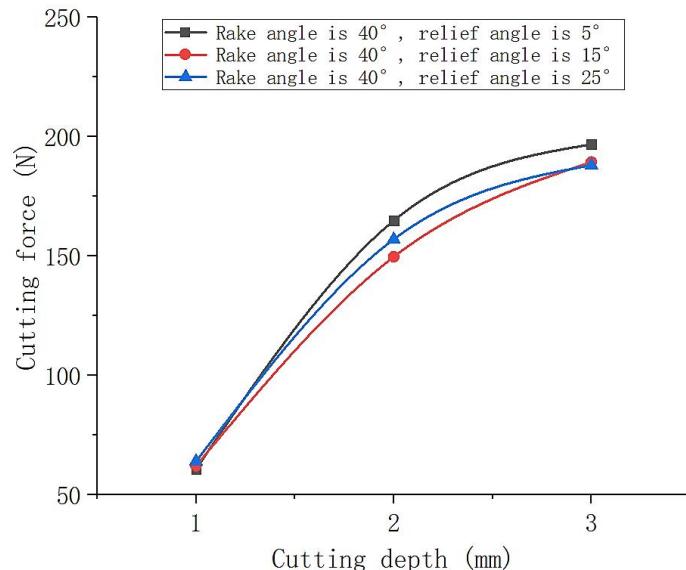

(a) The rotation speed of the drill bit is 50 rpm

342

(b) The rotation speed of the drill bit is 100 rpm

344

345

(c) The rotation speed of the drill bit is 100 rpm

347 **Figure 13.** Cutting force versus cutting depth

348 Under all experimental conditions, as the cutting depth increases, the cutting force shows a gradually
 349 increasing trend. When the cutting depth is 3mm, the maximum cutting force reaches 219.13725N. And,
 350 under the same experimental condition, the cutting depth increasing from 1 mm to 2 mm results in an
 351 approximate doubling of the cutting force. As the depth of penetration increases, the cutting force
 352 continues to increase, but the increasing trend gradually weakens.

353 **6. Conclusions**

354 It is preliminarily observed after the mechanical testing of ice, that the main damage form of ice is a
355 brittle fracture in the cutting process. During this process, the cutters press into the ice to a certain
356 depth and rotate, the ice withstands a squeezing effect from the rake face of the cutter and the shear slip
357 deformation occurs. When the shear slip deformation reaches a certain degree, the ice undergoes shear
358 failure and then forms ice chips. This process is constantly repeated throughout the cutting and drilling
359 of the ice.

360 Based on the characteristics of ice cutting and the stress characteristics during the ice cutting and
361 drilling process, a mechanical model of ice cutting was established. The mechanical model shows that
362 the cutting force is not only affected by the mechanical properties of ice but also by the cutting width,
363 cutting depth, and the rake angle of the cutter. As the cutting width and cutting depth increase, the
364 cutting force increases; as the increase of rake angle of the cutter, the cutting force decreases.
365 Additionally, the characteristics of cutting force were analyzed through experimental methods. The
366 experimental results show that the cutting force traces oscillated within a certain range, the oscillation
367 consists primarily of two frequencies. The higher frequency is related to the resolution of the sensor,
368 the lower frequency is related to the formation of large particle ice chips. the oscillation amplitude of
369 the cutting force traces is related to the cutting depth, as the cutting depth increases, the oscillation
370 amplitude of the trajectory will also increase. In addition, the oscillation amplitude will also affect the
371 quality of the core, as the amplitude increases, the possibility of the ice core breaking will also increase,
372 and the quality of the ice core will also increase accordingly. It is necessary to control the cutting depth
373 reasonably during the cutting process to ensure the quality of the ice core. Finally, the influencing
374 factors and laws of cutting force were verified by analyzing the cutting force generated under various
375 experimental conditions.
