9 **Abstract.** Nitrate ( $\text{NO}_3^-$ ), mainly leaching with soil pore water, is the primary nonpoint source pollutant of  
10 groundwater worldwide. Obtaining real-time information on nitrate levels in soils would allow gaining a  
11 better understanding of the sources and transport dynamics of nitrate through the unsaturated zone.  
12 However, conventional nitrate detection techniques (e.g. soil sample analysis) necessitate costly,  
13 laboratory-grade equipment for analysis, along with human resources, resulting in a laborious and time-  
14 intensive procedure. These drawbacks raise the need to develop cost-effective and automated systems for  
15 in situ nitrate measurements in field conditions. This study presents the development of a low-cost, portable,  
16 automated system for field measurements of nitrate in soil pore water and open water bodies. The system  
17 is based on the spectrophotometric determination of nitrate using a single reagent. The system design and  
18 processing software are openly accessible, including a building guide, to allow duplicating or changing the  
19 system according to user-specific needs. Three field tests, conducted over five weeks, validated the system's  
20 measurement capabilities within the range of 0-10 ppm  $\text{NO}_3^-$ -N with a low RMSE of  $<0.2$  ppm  $\text{NO}_3^-$ -N  
21 when comparing the results to standard laboratory nitrate analysis. Data derived from such a system allow  
22 tracking of the temporal variation in soil nitrate, thus opening new possibilities for diverse soil and nutrient  
23 management studies.

## 24 **1. Introduction**

25 Nitrogen (N) is a macro-nutrient found in soil, groundwater, and open water bodies across the globe.  
26 Nitrogen is essential for crop production and applying nitrogen-based fertilizers is a common practice in  
27 agriculture. However, excess fertilization leads to low nitrogen use efficiency (NUE) and can cause  
28 groundwater contamination due to leaching of excess nitrate ( $\text{NO}_3^-$ ) in the soil, which is the mobile form of  
29 nitrogen and is easily transported by water (Ascott et al., 2017; Turkeltaub et al., 2021; Levintal et al.,  
30 2023). Nitrate leaching from agricultural soils through the vadose zone has become the primary nonpoint  
31 source pollutant of groundwater (Ascott et al., 2017; Richa et al., 2022; Gurdak and Qi, 2012). Elevated

32 nitrate concentrations in open water, in addition to groundwater, are also considered a major global threat  
33 that can cause algae blooms and loss of aquatic life (Van Metre et al., 2016; Wherry et al., 2021).

34 Optimizing fertilization by applying the needed amount of nitrogen fertilizer for the crop at each growing  
35 stage can reduce the environmental risks above. To achieve this, real-time information on soil pore water  
36 nitrate levels is required (Yeshno et al., 2019), leading to a need for an accessible method to measure real-  
37 time nitrate concentrations in soils. However, measuring continuous in situ soil pore water nitrate  
38 concentrations is still a major environmental and agricultural challenge. During the last two decades,  
39 different soil pore water nitrate characterization technologies were tested, including ion-selective  
40 electrodes, portable spectrophotometers coupled with suction cups, and lab-on-a-chip technologies  
41 (Bristow et al., 2022).

42 The majority of published nitrate sensing systems for soil pore water show promising directions, however,  
43 they are limited to only lab tests, require complicated and repeated calibration procedures, or may be  
44 considered as a proof-of-concept rather than a functional field system (e.g., Ali et al., 2019; Chen et al.,  
45 2023; Tuli et al., 2009). Only two published studies, as far as we know, showed significant progress in  
46 measuring soil pore water nitrate concentrations continuously in the field. Bristow et al. (2022) developed  
47 ion-selective electrodes for soil nitrate sensing. The electrodes were field tested under a relatively high  
48 nitrate measurement range of ~50-300 ppm  $\text{NO}_3^-$ -N with a reported Root Mean Square Error (RMSE) of  
49 ~16 ppm  $\text{NO}_3^-$ -N. They described significant drift after eight weeks of field deployment that required the  
50 development of a correction algorithm. In general, electrode fouling, drift, ion interference, limited  
51 sensitivity, and the need for temperature compensation are major disadvantages of ion-selective electrodes  
52 (Tuli et al., 2009).

53 Yeshno et al. (2019) presented a monitoring system for continuous measurements of nitrate concentrations  
54 in soil pore water. Their system is based on ultraviolet (UV) absorbance spectroscopy to directly determine  
55 nitrate without pretreatment of the sample, such as filtration or adding reagents. The system was tested at  
56 four agricultural field sites during four sampling campaigns. The nitrate measurement range was ~10-350  
57 ppm  $\text{NO}_3^-$ -N (no RMSE was reported). The main advantage of the system is the durability and lack of  
58 needed field calibration, thus we consider this system as the most advanced and robust solution for field  
59 nitrate measurements currently available. Yet, the methodology is patented with no assembly details  
60 provided, and therefore, it cannot be duplicated and deployed by other users.

61 This study describes the construction and performance of a portable, low-cost, automated system for pore  
62 water nitrate measurements. The system is based on a spectrophotometer coupled with an array of pumps  
63 and a suction cup installed in the soil. A comprehensive technical documentation encompassing system

64 design, assembly, programming, deployment, power management, and data analysis is included to allow  
65 end-users to replicate, modify, and deploy the system to their specific requirements without requiring prior  
66 engineering expertise. For validation, three field tests with a concentration range of 0-10 ppm NO<sub>3</sub><sup>-</sup>-N were  
67 conducted over five weeks.

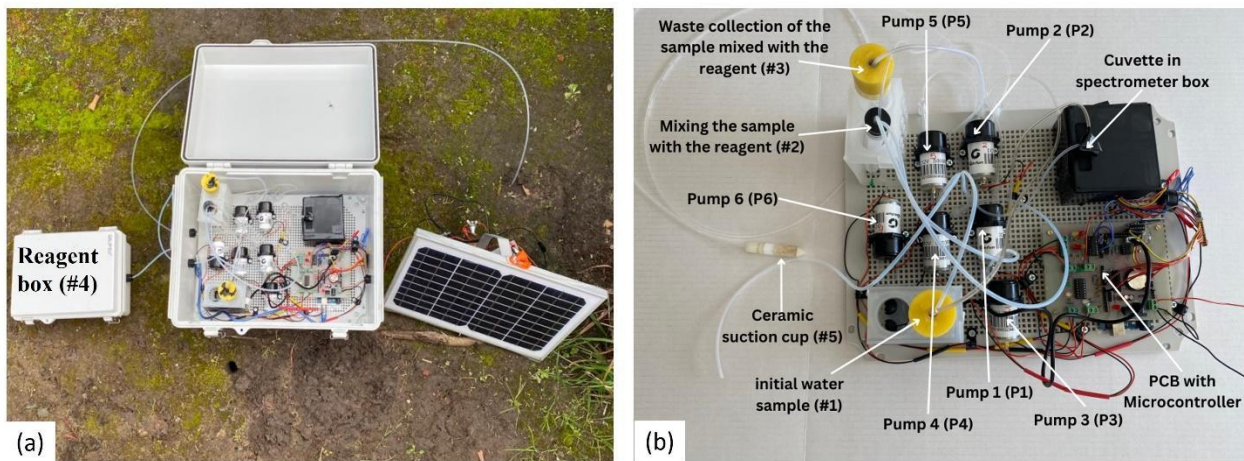

## 68 **2. Materials and Methods**

69 The system is based on the spectrophotometric determination of nitrate using a single reagent (Doane and  
70 Horwáth, 2003). Each water sample is mixed with a reagent (Vanadium(III) chloride (VCl<sub>3</sub>) +  
71 Sulfanilamide + *N*-(1-naphthyl)ethylenediamine dihydrochloride (NEDD)) and then measured at 540 nm  
72 wavelength. The absorption intensity is used to determine the nitrate concentration using a calibration curve  
73 as detailed below.

### 74 **2.1. Hardware**

75 The field nitrate sensing system is established on the open-source hardware concept (Pearce, 2012, 2014)  
76 and consists of three segments: the spectrophotometer, the hydraulics system, and the control unit (**Fig. 1a**).  
77 The low-cost spectrophotometer is based on the design by Laganovska et al. (2020), utilizing the  
78 C12880MA mini-spectrometer chip (Hamamatsu Photonics K.K., Japan). The device measures absorption  
79 in the 450-750 nm range, yet we use only the 540 nm wavelength. The 3D-printed measurement box holds  
80 the cuvette for sample measurements (**Fig. 1b**).

81 The hydraulics system consisted of six peristaltic dosing pumps, a set of 1/16" (1.57 mm) inner diameter  
82 tubing, a 50 mL container for collecting the initial water sample (#1), a 15 mL container for mixing the  
83 sample with the reagent (#2), a 50 mL container for post-processing waste collection of the sample mixed  
84 with the reagent (#3), a reagent box (#4), and a ceramic suction cup used to collect the water samples from  
85 the tested soil or water body (#5) (**Fig. 1a** and **1b**). The first pump (P1) is connected to the ceramic suction  
86 cup for sample collection. The rest of the pumps work in coordination to mix the appropriate sample volume  
87 with reagents, deposit it in the cuvette, and then clean the tubes and cuvette once the measurement is taken.  
88 The spectrophotometer and hydraulics system are controlled using an open-source microcontroller  
89 (Arduino Mega, Arduino, Italy) with a micro-SD card for data logging. The system is powered by a 12 V,  
90 7 Ah battery connected to a 10 W solar panel. Hardware details, system assembly instructions, and pumps  
91 sequence are provided on our GitHub page <https://github.com/SahitiB/AGNET/tree/main>.

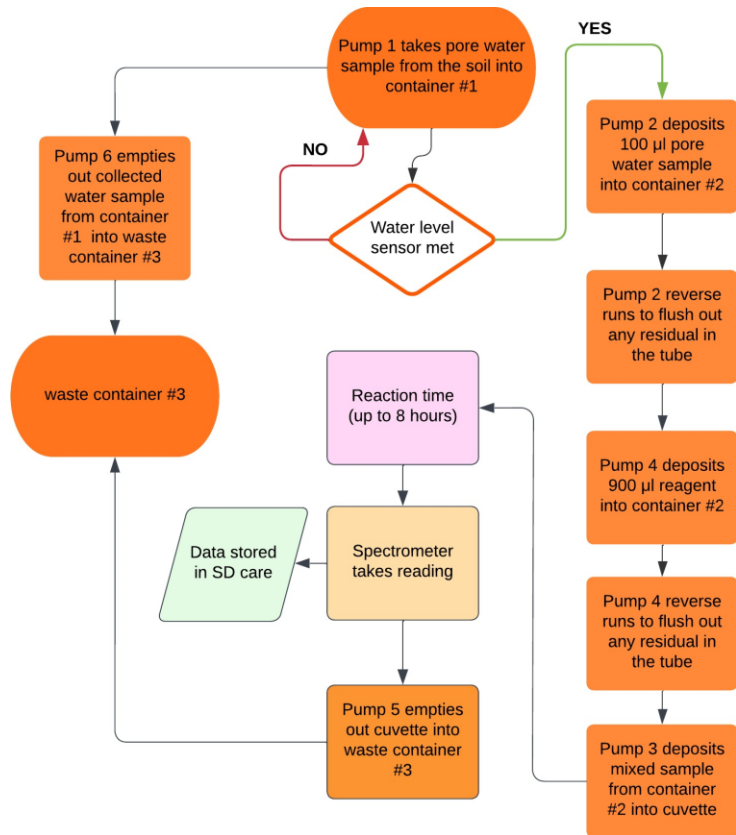

92 (a)

93 **Figure 1.** Experimental setting. The complete system during soil testing (a) and zoom in on the main box  
 94 (b). We note that the spectrophotometer unit is based on the design by Laganovska et al. (2020).

95 **2.2. Software**

96 An Arduino Mega microcontroller controls the device. Programming the Mega is done using C++, the  
 97 default language of the Arduino Integrated Development Environment (IDE)  
 98 ([www.arduino.cc/en/software](http://www.arduino.cc/en/software)). The code contains the functions required to control the sequence of events  
 99 for the entire system as well as the process of the spectrophotometer's results. The order and runtime of the  
 100 pumps are controlled through the code and can be changed as needed. The complete code and open license  
 101 conditions are described in our Github page <https://github.com/SahitiB/AGNET/tree/main>.

102 The flowchart in **Fig. 2** shows the sequence of a single nitrate measurement event, as instructed by the code.  
 103 First, P1 pumps a soil pore water sample through the ceramic suction cup into container #1 until the water  
 104 level sensor attached to the container is met at a sample volume of 5 mL. Then, P2 pumps 0.1 mL of the  
 105 collected sample into container #2, followed by P4 pumping 0.9 mL of the reagent into the same container  
 106 #2. The mixed sample is then transported to the cuvette (**Fig. 1b**, black box) using pump P3. Once the  
 107 passive reaction time of 8 hr is completed, the spectrophotometer reading is taken and pumps P5 and P6  
 108 vacuum empty out the cuvette and container #1, and the entire system is thoroughly cleaned, emptied, and  
 109 readied for the next cycle. The user can change the frequency between nitrate measurement events  
 110 according to needs and battery consumption as detailed below.

111

112 **Figure 2.** A flow chart of the main sequence in a single nitrate measurement event. A more detailed  
 113 description for each step is given on our GitHub page.

114 **2.3. Field deployment**

115 The system was calibrated using standard nitrate samples of 0, 0.1, 0.3, 1, 3, 5, 8, and 10 ppmNO<sub>3</sub><sup>-</sup>-N. After  
 116 running those samples mixed with reagent through the spectrophotometer, a calibration curve (Beer-  
 117 Lambert curve) is created relating the spectrophotometer absorbance values vs. the standard nitrate samples.  
 118 A calibration curve is constructed before each experiment. Three field tests were conducted to evaluate  
 119 system performance – two tests were run on soil pore water samples and one using open water samples.  
 120 The tests were all carried out in Fremont, California, between February and June 2023. For each test, field-  
 121 measured nitrate concentrations were compared against laboratory measurements with a Shimadzu 206-  
 122 24000-92 UV/Visible scanning spectrophotometer at the University of California, Davis for validation. For  
 123 the validation, sub-samples were directly taken from the water sample container (#1) after the pore water  
 124 sample was obtained but before adding the reagent. Comparison of the field-measured nitrate with the  
 125 standard laboratory method was done in several ways.

126 First, we conducted the variable test, which aimed at testing the accuracy of the system by randomly varying  
 127 the amount of nitrate fertilizer in the soil during irrigation (Scotts Liquid Turf Builder with Plus 2 Weed

128 Control (25% nitrogen content), Scotts, USA). This tested the ability of the system to detect shifts in nitrate  
 129 levels. Secondly, a continuous test was performed to examine the system stability under rain conditions and  
 130 the ability to measure nitrate leaching in soil. The variable test ran for seven days with two readings per  
 131 day, and the continuous test ran for 17 days with one reading per day. In both tests, the suction cup was  
 132 installed at a depth of 6.3 cm (2.5 in) in the soil, and the system operated autonomously without any  
 133 maintenance. The third test was the open water pulse test to validate the ability of the system to measure  
 134 nitrate in water bodies (e.g., rivers and lakes). The suction cup was submerged in a 12 L water bucket for  
 135 12 days with one reading per day. Every fourth day, a 0.5 L cup of nitrate-based fertilizer (same as above)  
 136 was added to the water bucket to test the ability of the system to detect changes in nitrate levels in open  
 137 water. Atmospheric measurements for the experiments were taken from the California Irrigation  
 138 Management Information System station (CIMIS; station 171 Union City, CA).

### 139 3. Results and Discussion

#### 140 3.1. System performances

141 A summary of the calibration and experimental results is presented in Table 1. One example of the Beer-  
 142 Lambert calibration curve is displayed in **Fig. 3**. The high  $R^2$  of 0.998 between the absorption and the  
 143 standard nitrate samples validates the linearity of our spectrophotometer and the capability to accurately  
 144 measure nitrate.

145 **Table 1.** Summary of the calibration and experiment results

Experiment type	Duration and sampling rate [d]	Range of tested nitrate [ppm $\text{NO}_3^-$ -N]	Average RMSE [ppm $\text{NO}_3^-$ -N]
Calibration	One day	0-10	n/a
Soil variable test	Seven days (twice per day) 13/2/2023-19/2/2023	0-0.97	0.09
Soil continuous test	17 days (once per day) 28/2/2023-16/3/2023	0-2.39	0.10
Open water pulse test	12 days (once per day) 10/6/2023-21/6/2023	0-7.29	0.20

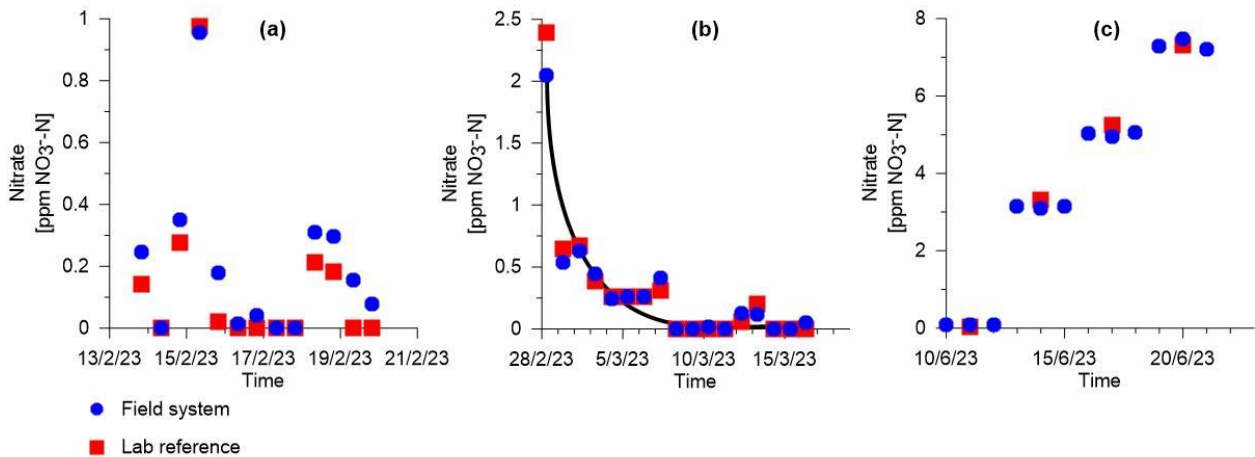

146

147

148 **Figure 3.** Beer-Lambert calibration curve for the system spectrophotometer using known standard nitrate  
 149 concentrations of 0, 0.1, 0.3, 1, 3, 5, 8, and 10 ppm of NO<sub>3</sub><sup>-</sup>-N.

150 The first variable test focused on the low range of nitrate in the soil < 1 ppm NO<sub>3</sub><sup>-</sup>-N. During the seven-day  
 151 test, the system was successful in measuring the changes in nitrate level with a RMSE of 0.09 ppm NO<sub>3</sub><sup>-</sup>-  
 152 N compared to the lab reference analysis (**Fig. 4a**). We consider this as a low error value that validates our  
 153 system in the low concentration range of nitrate. The soil continuous test showed similar high accuracy  
 154 throughout the 17 days of trial with an average RMSE of 0.10 ppm NO<sub>3</sub><sup>-</sup>-N (**Fig. 4b**). The stability of  
 155 measurements during this period suggests that no degradation of system performance was occurring with  
 156 all measurement cycles conducted successfully. This 17-day test was conducted during a significant rain  
 157 event with 12.2 mm d<sup>-1</sup> of rainfall occurring on the first day. Therefore, we were able to measure, in real-  
 158 time, the nitrate leaching in the topsoil (marked by the black curve line in **Fig. 4b**). The third test was  
 159 conducted to validate the system in open water (**Fig. 4c**). In this case, the suction cup was submerged in a  
 160 12 L water container, and nitrate-based fertilizer was added every fourth day. RMSE remained low with  
 161 0.20 ppm NO<sub>3</sub><sup>-</sup>-N. The first step of water sampling using P1 was drastically faster compared to the soil  
 162 tests, reducing the pump time from 30-40 min to 5-10 min per cycle.

163

164 **Figure 4.** Experimental results of the spectrophotometer testing for the soil variable test of low nitrate  
 165 concentrations (a), the soil continuous test under a rain event (b), and the open water pulse test (c). The  
 166 black line in subplot (b) marks the nitrate leaching after a rain event of 12.2 mm d<sup>-1</sup> on 28/2/2023. For each  
 167 concentration level in the open water pulse test in subplot (c), three field measurements (blue dots) were  
 168 compared to one laboratory measurement (red squares).

169 **3.2. System limitations and modifications**

170 In this study, we presented and tested a portable, low-cost field nitrate sensing system to measure in situ  
 171 nitrate concentrations in soil pore water and aquatic environments. Although the system is autonomous in  
 172 terms of obtaining a sample and processing it until a nitrate concentration is determined, it does require  
 173 some user input. The main user input required involves replacing the dry ice in the reagent box to maintain  
 174 the recommended temperature of 4 °C for the Vanadium III Chloride reagent to work at its optimum (**Fig.**  
 175 **1a**). In our experiments, replacing the dry ice every five days was sufficient to ensure this temperature,  
 176 however, all experiments were conducted at an average daily air temperature of 10 °C with a daily  
 177 maximum of ~20 °C. Warmer conditions will require a more frequent replacement time of the dry ice or  
 178 adding a cooler box or more advanced solutions, such as a small field refrigerated unit or a Peltier cooling  
 179 plate based on solar panel or gas. Improving the reagent chill-box will increase system cost yet reduce  
 180 human dependency. This, together with the addition of a low-cost modem or wireless communication such  
 181 as Wifi or LoRa (Bristow et al., 2022; Sanchez-Iborra et al., 2018; Levintal et al., 2021), will make the  
 182 device completely autonomous for weeks to months.

183 The system, considering our sample to reagent ratio, can accurately measure nitrate concentrations up to  
 184 ~10 ppm NO<sub>3</sub><sup>-</sup>-N. This is a well-known limitation (Doane and Horwath, 2003) of using the Vanadium III  
 185 Chloride reagent, which also exists in the lab. It would be possible to increase the range with the current  
 186 system by either increasing the amount of reagent, decreasing the amount of sample, or both. However,

187 further experiments would be necessary to implement and test this extended range. When analyzing samples  
188 with higher concentrations (70-80 ppm  $\text{NO}_3^-$ -N), adding the reagent results in unusual colors (salmon,  
189 orange, and yellow) that cannot be accurately measured and calibrated using known concentration standards  
190 and the spectrophotometer. For example, a sample with a high concentration (e.g., approximately 120 ppm  
191  $\text{NO}_3^-$ -N) will turn yellow and the spectrophotometer will register absorbance corresponding to  
192 concentrations lower than 1 ppm  $\text{NO}_3^-$ -N, indicating a false reading. A possible solution could be the  
193 addition of a visual color sensor to notify the user when the color is exceeding the concentration range  
194 covered by the standard (i.e., high nitrate concentrations) to then dilute the sample accordingly. This will  
195 require changing the design of the system and adding a dilution mechanism.

196 If a high measurement frequency is required, a heating device can be added, or a temperature curve can be  
197 developed to reduce the 8-hour reaction time of the Vanadium III Chloride reagent in the cuvette. Yet, this  
198 need is highly site-specific as warmer climates will reduce the sample-reagent time naturally. Higher  
199 measurement frequency means higher power consumption, which should be optimized using a larger  
200 battery capacity and/or a larger solar panel. In our experiments, taking the soil variable test as a reference  
201 (**Fig. 4a**), the 12 V, 7 Ah with a 10 W solar panel was sufficient for two samples per day for seven  
202 continuous days. This was achieved under cloudy skies with an average daily solar radiation of  $156 \text{ W m}^{-2}$ .  
203 Power consumption is site-dependent due to the variability in the solar panel's efficiency to charge a 12  
204 V battery, and moreover, due to the changes in soil moisture. Lower soil moisture will increase the run time  
205 of the peristaltic pump extracting the water sample from the soil (P1 in **Fig. 1**), therefore increasing power  
206 consumption for each nitrate sampling cycle. In very dry conditions, water samples cannot be extracted  
207 from the soil and the system will not work. A possible optimization solution could be the addition of a soil  
208 moisture sensor to deactivate the system under very dry conditions. We note that this is a common problem  
209 of using suction cups in dry soils unrelated to this specific system.

210 This study demonstrates the capabilities to measure nitrate leaching during a rain event and nitrate changes  
211 in open water. Additional potential research objectives for the low-cost portable nitrate system include: (1)  
212 measuring soil nitrate levels in the root zone of an agricultural field during a growing session to optimize  
213 nitrogen fertilization applications, i.e., precision agriculture methods to reduce groundwater pollution  
214 (Yeshno et al., 2019). This application will need to include a soil moisture sensor to allow the calculation  
215 of the nitrate stock available for plant uptake (Bristow et al., 2022); (2) couple the system with low-cost  
216 oxygen sensors (Levintal et al., 2022) to investigate in real time the occurrence of denitrification and its  
217 dependency on soil oxygen levels (Levintal et al., 2023); (3) measure nitrate changes in lakes/rivers during  
218 heavy rain events or floods, and (4) implementing the same design to measure other contaminants in the

219 soil pore water and open water given that they have distinct absorbance in the range of our  
220 spectrophotometer of 450-750 nm.

#### 221 **4. Summary**

222 This study presents the development of a low-cost, portable, automated system for field measurements of  
223 nitrate in soil pore water and open water bodies. The system consists of an Arduino-controlled array of  
224 pumps, a suction cup installed in the soil, and a spectrophotometer that measures the nitrate concentration  
225 after the water sample is mixed with a reagent. Three field tests conducted over five weeks to validate the  
226 system within a measurement range of 0-10 ppm  $\text{NO}_3^-$ -N showed a low RMSE of  $<0.2$  ppm  $\text{NO}_3^-$ -N when  
227 comparing the results to standard laboratory nitrate analysis. This nitrate range is suitable for soils with low  
228 nitrate concentrations or open water. The system design and processing software are openly accessible. By  
229 designing a system in which all electronics are limited to buyable hardware components and the files for  
230 the printed circuit board (PCB) are provided, it is possible to duplicate or change the system according to  
231 user-specific needs. The total cost of the system components is USD \$1,100, excluding reagents, which we  
232 hope will allow reproducibility and open new possibilities for conducting field studies in soil and  
233 environmental nitrate monitoring.

234

235 **Code and data availability**

236 The complete technical guide and code are available in our GitHub repository  
237 (<https://github.com/SahitiB/AGNET/tree/main>)

238 **Author contributions**

239 EL conceptualized the study and designed the system, SB constructed the system and conducted the study,  
240 SB and EL wrote the first manuscript draft, HED provided the resources and project supervision. All the  
241 authors (SB, CPG, HED, and EL) contributed to the final version.

242 **Competing interests**

243 The contact author has declared that none of the authors has any competing interests.

244 **Acknowledgments**
