19

20 **Abstract.** ~~The A massive eruption of~~ Okmok volcanic eruption in Alaska has been recently  
21 discovered and precisely dated to have occurred in 43 BCE. Some Chinese climate records of 43  
22 - 33 BCE in historical documents have been found that provide descriptions of observed  
23 environmental abnormalities that appear to be consistent with the anticipated changes due to  
24 volcanic climate forcing. We provide full translation with discussions of the Chinese climate  
25 records that may be related to the Okmok eruption in this paper. We have converted ancient  
26 Chinese calendar dates to modern Gregorian dates and provided the latitudes and longitudes of  
27 the geographical locations mentioned in the records. Some information about the few decades of  
28 post-Laki 1783 eruption climate condition in similar areas of China is also briefly summarized  
29 for comparison. We believe the detailed information contained in these records will be useful for  
30 further research on the climate impact of volcanic eruptions.

31

## 32 **Summary**

33 We provide detailed translation of some abnormal meteorological conditions in 43-33 BCE  
34 described in Chinese historical documents possibly related to the Okmok volcanic eruption in  
35 Alaska in early 43 BCE. The cold summer record and the abnormal color and low brightness of

36 the sun point to the clear link to the volcanic impact. The reported duration for the visual  
37 condition of the sun to return normal should be useful for researchers modeling the volcanic  
38 impact on climate.

39

## 40 **1. Introduction**

41 It has been known for some time that volcanic eruptions are an important forcing in  
42 shaping the global climate (Bradley 2015; Gao et al. 2008) and some recent events, such as  
43 the eruption of Pinatubo in 1991 that caused discernable climate cooling have been studied  
44 and reported (e.g., McCormick et al. 1995; Sukhodolov et al. 2018). Since climate change is  
45 a globally urgent issue facing the human society and that predictions of future climate change  
46 rely mainly on climate models which, at present generation, still produce results with large  
47 uncertainties (IPCC, 2023), it is of great importance to improve and validate these models.  
48 One common practice is to run these models to back-predict the past climate during a certain  
49 period with known forcing terms and compare the model results with observations. An  
50 example of such activities is PMIP which stands for Paleoclimate Model Intercomparison  
51 Project (see, e.g., Jungclaus et al., 2017). But this requires high quality past climate data and  
52 evidence of events that might indicate important climate forcing. Given high impact of  
53 volcanic forcing on climate change, obtaining accurate volcanic eruption records is evidently  
54 highly important.

55 Large explosive volcanic eruptions exert short-term cooling on the global climate which  
56 counteracts the greenhouse gas-induced warming and, by doing so, may alter climate  
57 conditions of certain regions. For example, this cooling has been suggested to reduce land-  
58 sea thermal contrast and suppress summer precipitation, especially in low-latitude monsoon  
59 regions (Gao and Gao, 2018; Iles & Hegerl, 2014; Schneider et al., 2009; Robock et al.,  
60 2008). Changes in monsoon rainfall have great repercussions on the food production and  
61 human societies in these areas. Thus, it is obviously important to understand these large  
62 eruptions and their impacts on climate.

63 A recent study revealed a previously unreported volcanic eruption occurred in Mount  
64 Okmok in Alaska with an unprecedented accurate dating technique and pinpointed that the  
65 eruption occurred in early 43 BCE (McConnell et al. 2020). Such accurate dating is very

66 important in that it can link unambiguously with other records describing climate-related  
67 phenomena observed at the same time to form a complete cause-and-effect chain, and such a  
68 chain becomes a valuable data for climate model validation: Only those models that include  
69 the right causes at the right moment through the right physical sequence and produce the  
70 accurate effect as observed can be considered as validated for this forcing. The records  
71 discussed here reveal such a cause-and-effect chain.

72 In interpreting the climate change, we also need to keep in mind that the climate is  
73 governed by the complex interactions among various external forcing and internal modes,  
74 and volcanic responses can invoke but also easily ~~overwritten~~overridden by internal modes  
75 such as ENSO. This is certainly true in East Asia also. Sometimes the climate signals of these  
76 factors overlap and render the determination of the causes difficult. In addition, the  
77 reconstructed climate change may look different when interpreted by different sets of proxy  
78 data. For example, Gao et al. (2017) demonstrated that a discrepancy exists between the  
79 reconstruction by Anchukaitis et al. (2010) based on the tree ring-derived Monsoon Asia  
80 Drought Atlas (MADA, see Cook et al., 2010) and that by Chinese historical documents  
81 when analyzing the climatic responses in China after the 1815 Tambora eruption. Later, Feng  
82 et al. (2013) used a multiproxy-based reconstruction that supports the document-based  
83 reconstruction (Gao and Gao, 2018). This underlines the importance of accurate data sets for  
84 climate studies.

85

## 86 **2. Okmok eruption in 43 BCE and contemporary Chinese climate records in 43-33 BCE**

87 Chinese historical documents contain many records that contain information about the  
88 climate conditions of the time. Many of these have been utilized for the reconstruction of past  
89 climate in China in the historical time (see, e.g., Wang, 1979, 1980; Wang & Zhang, 1988,  
90 1991, 1992; Zhang & Wang, 1991). We have recently digitized the climate records in China  
91 in the past 3000 years listed in Zhang (2013) by designing an extensive dictionary to convert  
92 these records into digital form to build a climate database called REACHES such that  
93 researchers can utilize these records even if they are not familiar with Chinese language  
94 (Wang et al. 2018; Lin et al. 2020).

95           Among these ancient records, one that had caught our attention long time ago is the ‘cold  
96 summer’ record dated at 43 BCE as it is the first such report with precise timing in an official  
97 national chronicle, *Han Shu* (literally the History of Han Dynasty), about which more will be  
98 said later. This and other sequel records at that time are, in our opinion, of importance for  
99 understanding the impact of volcanic eruptions on global climate. They had been briefly  
100 mentioned in McConnell et al. (2020) but without much details. It is felt that by providing the  
101 full contents of these Chinese records, climate researchers can profit by digging deeper into  
102 this event and scrutinizing the meaning of the descriptions of the records. This will lead to a  
103 better understanding of the volcanic impact on climate both qualitatively and quantitatively.

104           In the following, we will provide full translations of these records that we deem relevant  
105 to the Okmok eruption along with our observations and interpretations that we believe would  
106 be useful.

107           We use the online utility <http://www.nongli.net/sxwnl/> to convert the Chinese calendar to  
108 Gregorian calendar. The approximate latitudes and longitudes of the locations mentioned in  
109 these records were determined using the historical GIS developed in Academia Sinica (Liao  
110 and Fan 2012). If a record contains no specific location name, then it was an event usually  
111 observed at the national capital at the time, i.e., Changan (長安, 34.03899° N, 108.9311° E).  
112 All events discussed below occurred during the reign of Emperor Yuan of Han Dynasty (漢  
113 元帝) who ruled China in the period 48-33 BCE. Starting in 140 BCE, it became a tradition  
114 of Chinese imperial systems to give a special name to the years of a certain period, called era  
115 name, during the reign of an emperor. There might be several such eras during the reign of an  
116 emperor if deemed necessary. Even though Emperor Yuan only reigned 16 years, he had four  
117 such eras: Chu Yuan (初元 48-44 BCE), Yong Guang (永光 43-38 BCE), Jian Zhao (建昭  
118 38-33 BCE), and Jing Ning (竟寧 33 BCE).

119           All records discussed below were derived from the following five original Chinese  
120 historical documents as well as in Zhang (2013):

121 #1 – Annals of Emperor Yuan, *Han Shu* (漢書 元帝紀)

122 #2 – Records of Five Elements, *Han Shu* (漢書 五行志)

123 #3 – Biography of Feng Fengshi, *Han Shu* (漢書 馮奉世傳)

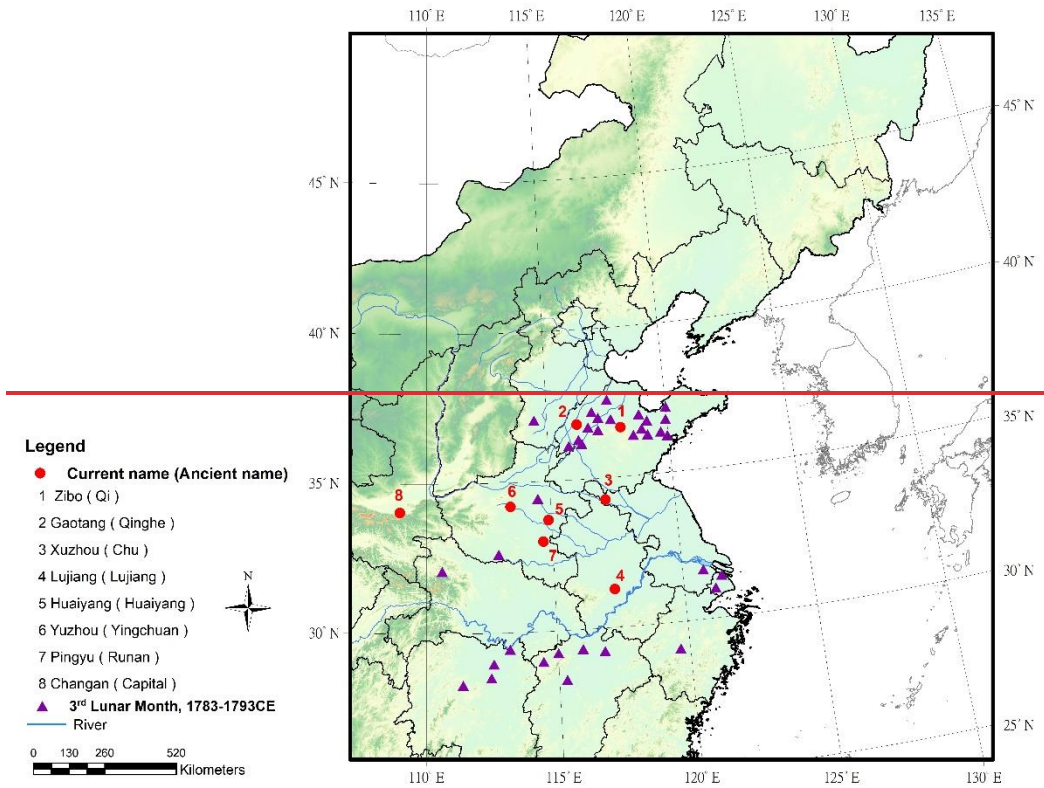

124 #4 – *Lord Fu's Notes of Ancient and Contemporary Affairs* (伏侯古今注)

125 #5 – *Comprehensive Reflections to Aid in Governance* (資治通鑑)

126 The first three documents are all from *Han Shu* authored by Ban Gu (32-92 AD) who was  
127 the pioneer of Chinese chronological history. #2 contains a large amount of observed  
128 abnormal environmental phenomena. #4 was written by Fu Wuji (circa 130 AD). Both Ban  
129 Gu and Fu Wuji lived in Han Dynasty. #5 was a comprehensive reference compiled in Song  
130 Dynasty led by Sima Guang (1019-1086 AD) based on the imperial historical documents. We  
131 use the numerical indices to indicate the source of the records (at the end in parenthesis) in the  
132 following discussions. The records are listed in chronological order.

133 Fig. 1 shows a map of the locations mentioned in the discussions below.

134

135

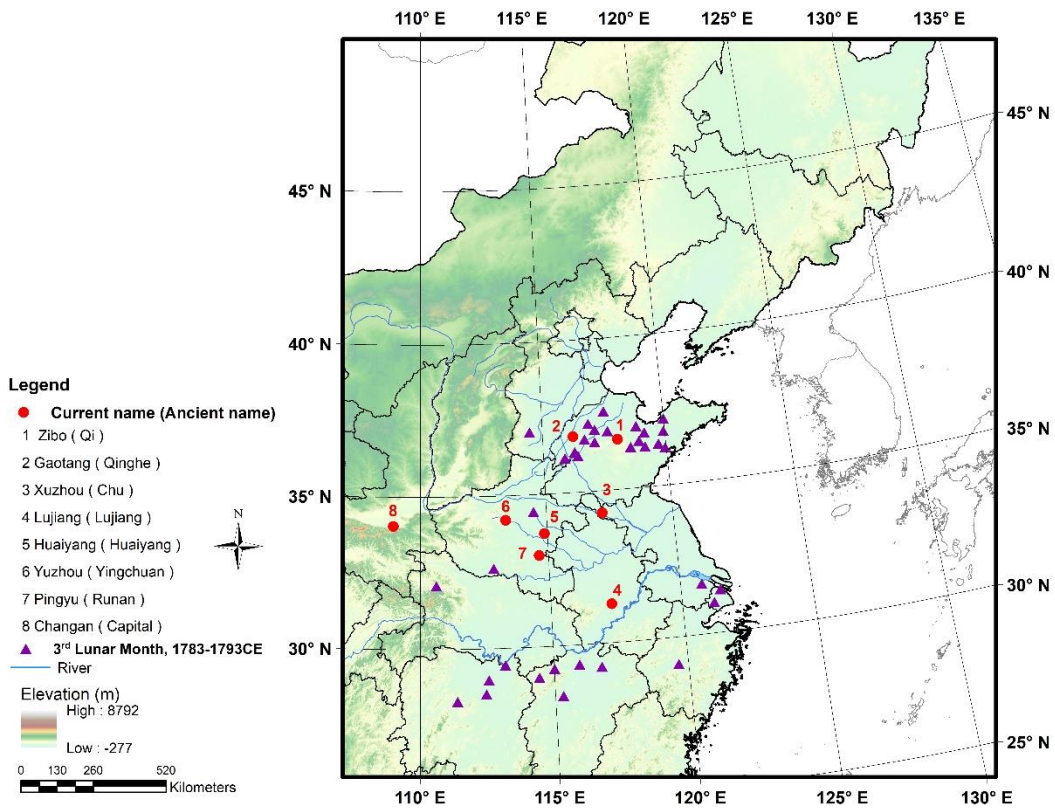

Fig. 1. A map showing the locations mentioned in the text. Red circular dots are those associated with the Han dynasty records (location names in the legend). ~~Blue~~ ~~Purple~~ triangles are those associated with the cold records in the general area of central China in the period of ~~1733~~ ~~1783~~ - ~~1833~~ ~~1793~~.

**a) 43 BCE (Yong Guang 1<sup>st</sup> year)**

- i) “In 3<sup>rd</sup> Month (8 April – 6 May), snowfall. Frost damaged wheat crops. No harvest in the fall” (#1)
- ii) “In 3<sup>rd</sup> Month, frost damaged mulberry” (#2)
- iii) “In 4<sup>th</sup> Month (7 May – 5 June), the sun was bluish-white in color and casted no shadow. When the sun reached the zenith, it did cast shadow but had no glare. The summer was cold. The glare of the sun recovered in the 9<sup>th</sup> Month (2 - 31 October)” (#2)
- iv) “On 2<sup>nd</sup> Day of 9<sup>th</sup> Month, frost damaged crops. Severe famine occurred in the whole country” (#2)

Of the above four records, iii) is the most directly relevant to the volcanic eruption, hence we will discuss it first. Coloration of the sky and that of the celestial objects in it can be an important indication of the presence and the altitude level of the volcanic dusts. For example, Guillet et al. (2023) utilized the coloration of the moon during total moon eclipses to determine the stratospheric turbidity so as to infer the occurrence of climate-forcing volcanic eruptions. In this record, the original Chinese characters describing the color of the sun in this record was 青白 (qing bai) which can be translated as “greenish-white” or “bluish-white” due to the somewhat ambiguity of the meaning of “qing” in ancient Chinese language, as it could mean either “bluish” or “greenish”, but we shall use bluish-white for our discussion here. The description of sun color here already indicated that it was unusual, and the most likely cause, in light of the discovery of Okmok eruption, was that the sun was veiled by a thin layer of volcanic dusts in the sky. Such blue sun (and moon) phenomenon caused by volcanic ash has been observed repeatedly and lasted hours for a time during the 1883 Krakatau eruption (Minnaert, 1993).

The second important indication of the presence of volcanic ash is that the sun casted no shadow except when it was at zenith. Again, this was likely due to the presence of the

166 volcanic dusts that scattered sunlight, rendering the sky light a diffuse light source which  
 167 therefore casted no shadow (Minnaert, 1993). This effect is more pronounced when the sun  
 168 angle is low in the morning or in the later afternoon as the sun's rays have to go through a  
 169 thick layer of the atmosphere. When the sun is at the zenith, its rays go through a much  
 170 thinner layer of the atmosphere and therefore suffers less scattering and is capable of casting a  
 171 shadow. But obviously the scattering was substantial enough to reduce the glare of the sun as  
 172 described by the record.

173 The record indicates that that summer was cold. The use of 'cold' (寒) to describe summer  
 174 condition was rather unusual in Chinese historical records and must indicate a rather severe  
 175 departure from the norm. A few cold days in a summer may be not so unusual, but a whole  
 176 cold summer season must be extremely rare. Thus, we feel that the estimate of 2°C colder  
 177 than normal mean given in Tan et al (2003) is reasonable. ~~It is little doubt that such~~ cooling  
 178 ~~of such a magnitude was possible under must have been due to~~ the very strong volcanic  
 179 radiative forcing associated with the Okmok eruption.

180 The record then says that the sun glare recovered in the 9<sup>th</sup> Month, roughly 5 months after  
 181 the sighting of the unusual sun color. This should indicate how long the volcanic dusts  
 182 hovered over northern China in 43 BCE. This information should be of importance to  
 183 researchers trying to model the cooling and those interested in modeling the transport of  
 184 volcanic dusts to China from Okmok.

185 Now we can go back to examine records i) and ii), both indicate cold condition in the 3<sup>rd</sup>  
 186 month. Even though these events occurred before the sighting of the volcanic dusts, it was  
 187 still possible that the cold climate was caused by the volcanic forcing as the Spring time  
 188 weather of northern China is usually influenced strongly by the movements of polar air  
 189 masses. Okmok is located much further north than China, and the cold air mass originated in  
 190 Alaskan polar region can certainly influence the spring weather in Northern China. The  
 191 volcanic forcing could have caused colder-than-normal air masses that resulted the frosty 3<sup>rd</sup>  
 192 Month in China when they moved south.

193 Record iv) can be interpreted in a similar way. Even if the volcanic dusts had disappeared,  
 194 it is still possible that forcing effect lasted longer and hence the frost and famine could still be  
 195 attributed to the volcanic event.

196 **b) After 43 BCE**

197 It is known that the impact of volcanic eruption on climate can last many years if the dusts  
 198 reach high in the stratospheric level such as the case of Pinatubo eruption in June 1991  
 199 (McCormick et al. 1995). Hence it is also useful to list relevant climate records a few years  
 200 after the eruption event. In the next section, we list those records within 10 years after the 43  
 201 BCE Okmok eruption.

202 **i). 42 BCE (Yong Guang 2<sup>nd</sup> year)**

- 203 • In 6<sup>th</sup> Month (24 July – 22 August), the imperial decree declared “Recently, there  
 204 are years of poor harvest and all areas are in serious condition. People worked hard  
 205 on tilling but received no produce. They are suffering from famine and there is no  
 206 relief” (#1)
- 207 • At this time, there were many crop failures, ..., all areas are suffering famine” (#3)

208 These two records are essentially saying the same thing, namely, poor crop yield led to  
 209 famine which could be attributed to the cold climate. However, the term ‘years’ could  
 210 mean two or more years and therefore the climate that resulted in famine might or might  
 211 not relate to the Okmok eruption.

212 **ii) 41 – 40 BCE (Yong Guang 3<sup>rd</sup> year)**

- 213 • In 11<sup>th</sup> Month (7 December, 41 – 5 January, 40 BCE), the imperial decree declared  
 214 “(It) rained in mid-winter and heavy fog (occurred)” (#1)

215 The words in parenthesis are added by us to render the sentence easier to understand in  
 216 English. Rain in mid-winter is extremely rare in northern China now as well as then where  
 217 the capital of Han Empire, Changan, is located and this statement must indicate a severe  
 218 anomaly. Rain occurred in midwinter was presumably because the unusual warm weather  
 219 at this time. This was obviously not directly due to the negative radiative forcing of the  
 220 volcanic dusts, but could it be a climatic repercussion of the severe coldness of the  
 221 previous year? Similarly, the fog must have been extraordinary heavy to deserve a

222 mention in the decree. In addition, fog consists of liquid droplets (since the statement did  
 223 not say ice fog) and therefore this also indicated abnormally warm climate that winter. It  
 224 is not known that fog can be directly related to a volcanic event but it could also be a  
 225 result of repercussion. Both require further study in the future.

226 **iii) 39 BCE (Yong Guang 5<sup>th</sup> year)**

- 227 • In the fall (7 August – 6 November), Yingchuan (潁川 34.19589N, 113.3792E)  
 228 flooded and killed people (#1)
- 229 • Heavy flood in summer (5 May - 6 August) and fall. Rain in Yingchuan, Runan  
 230 (汝南 32.99044°N, 114.6317°E), Huaiyang (淮陽 33.70539°N, 114.8841°E) and  
 231 Lujiang (廬江 31.26964°N, 117.3212°E) damaged houses in rural areas and  
 232 causing flood that killed people. (#2)
- 233 • In this year, the Yellow River flooded at Lingmingdu Mouth (靈鳴犢口) of  
 234 Qinghe (清河 36.83046°N, 116.2479°E), but River Tunshi (屯溪 a tribute of  
 235 Yellow River) dried out. (Vol. 21, History of Han, #5)

236 All of these records mentioned flood and the second entry seems to indicate that the flood  
 237 was caused by heavy rain. Again, they were not directly related to the volcanic eruption  
 238 but might be its climatic repercussion.

239 **iv) 38 BCE (Jian Zhao 1<sup>st</sup> year)**

- 240 • In 8th Month (7 September – 6 October), large swarm of flying white moths  
 241 shrouded the sun (#1)

242 This is also not directly linked to the volcanic event but it is also possible that the unusual  
 243 biospheric phenomena might have been caused by the abnormal climate condition due to  
 244 the repercussion.

245 **v) 37 – 36 BCE (Jian Zhao 2<sup>nd</sup> year)**

- 246 • In 11<sup>th</sup> Month (23 December, 37 – 20 January, 36 BCE), earthquake occurred in  
 247 Qi and Chu. Big blizzard broke trees and damaged houses (#1)

248 The earthquake should not be related to the Okmok eruption, but the cold climate  
 249 that led to the strong blizzard could be due to it.

- 250 • In 11<sup>th</sup> Month, big blizzard occurred in Qi (齊 36.64394°N, 118.0556°E) and Chu  
251 (楚 34.27161°N, 117.2056°E) areas and was 5 *chi* (尺) deep (#2)

252 The information in this record is essentially the same as the one above but it gave an  
253 additional information on the snowfall amount, 5 *chi*. *Chi* is a Chinese length unit whose  
254 length varied from time to time historically. There were Han rulers unearthed and it was  
255 determined that one *chi* in Han dynasty is roughly 23.1 – 23.3 cm (Hsu 2009). 5 *chi* is  
256 therefore roughly 116 cm or 46.4 in, certainly an unusually heavy blizzard in these  
257 locations that could cause the disasters reported in the previous record.

- 258 • Jing Fang (77-37 BCE) from Dong Jun spoke to Emperor Yuan about the  
259 disasters and abnormalities, “Ever since Your Majesty ascended the throne, the sun and  
260 the moon had lost their glares, stars orbited reversely, mountains collapsed and springs  
261 gushed out from underground, the earth quaked and rocks fell, frost appeared in  
262 summer and thunders heard in winter, plants withered in spring and flowered in fall,  
263 frost unable to kill plants, and flood/drought and locust outbreaks occurred. People  
264 suffer from famine and plagues, bandits cannot be suppressed, and prisoners are  
265 everywhere. All the disasters and abnormalities mentioned in *Chun Chiu* (a chronicle of  
266 Lu Dukedom edited by Confucius) have happened” (Vol. 21, History of Han, #5)

267 According to traditional Chinese belief, abnormal natural phenomena, be it  
268 astronomical or earth environmental, occur because they reflect the health state of the  
269 political system. When auspicious phenomena (such as colorful clouds or large group  
270 gathering of cranes) occur, it must indicate that the system is running well and the  
271 emperor was considered virtuous and fit to rule. If ominous signs (such as what  
272 mentioned in this records) occur, then there must be something wrong in the system, and  
273 ideally a faithful government official should not be afraid to tell the truth to the emperor.  
274 These uncomplimentary comments from Jing Fang, a procurator and scholar known for  
275 his studies in divination, must have been very unpleasant to the royal ears as he attributed  
276 all these disasters and abnormalities to the incompetent rule of Emperor Yuan. It took a  
277 great courage for a low-level official to take such an action but this also indicates that

278 what he said about the abnormal climate events must have occurred, for otherwise it  
279 would be purely suicidal to make such statements.

280 Unfortunately, Jing Fang was framed by the head eunuch, Shi Xian, whom was the  
281 real target of Jing Fang's attribution, and eventually died in jail. Attributing these climate  
282 abnormalities to political incompetence is obviously unscientific, but there is no way Jing  
283 Fang could have known that the real culprit was a volcano some 6000 km from his  
284 country!

285 **vi) 35 BCE (Jian Zhao 4<sup>th</sup> year)**

- 286 • Dustfall (#4)

287 Unfortunately, there is no precise month given in this record and it was unclear whether this  
288 had a connection with the volcanic eruption or not.

289 There is another record listed under this year stating that “In 3<sup>rd</sup> Month, snowfall occurred  
290 and many swallow died”. However, this is possibly an error and the event should belong to one  
291 in 29 BCE, and the month should be 4<sup>th</sup> Month (Shi, 1994). This is beyond the 10-year period of  
292 interest here and will not be discussed.

293 **vii) 33 BCE (Jing Ning 1<sup>st</sup> year)**

- 294 • Heavy fog. All trees turned white. (#4)

295 Like the previous record, this record does not contain the month information and we don't  
296 know which season it belonged. It is also unknown why trees turned white. However, one  
297 possibility of trees turning white is that this was a freezing fog event such that fog droplets stuck  
298 on trees and turned into ice. If so, then this record can possibly be interpreted as indicating a  
299 colder-than-usual condition, especially if the fog did not happen in winter.

300 **3. A brief comparison with the possible responses in China in post-Laki period**

301 As mentioned before, the climate is governed by the complex interaction of many factors,  
302 therefore what described in the previous section should be taken as possible, but not definite,  
303 climate response of the Okmok eruption in China. Nevertheless, we believe the possibility is  
304 high, as we observe a similar climate fluctuation pattern in central China after another large  
305 eruption in 1783-1784, the Laki eruption in Iceland. Like Okmok case, the Laki eruption was a

306 high-latitude event and a strong one with a VEI (volcanic eruption index) at 4, and therefore we  
 307 would expect that it would have impact on the climate fluctuation in China at that period. Since  
 308 the winter season is normally cold in central and northern China, it would be more difficult to  
 309 attribute cold winters to the influence of volcanic eruption. Instead, we show the evidence of  
 310 cold climate in the 3<sup>rd</sup> month which corresponds to late spring in Chinese lunar calendar. This  
 311 season was generally regarded as warm and a time for flowers to blossom. Frost or snow in this  
 312 season should then indicate colder than normal condition. Fig. 2 shows the frequency of frost  
 313 and/or snow records in the 3<sup>rd</sup> month of the period 1733-1833 in northern and central China as  
 314 those mentioned in the last section. The exact locations of the records associated with the post-  
 315 Laki decade (1783-1793-are) are shown in Fig. 1 as purpleblue triangles. We can see that they  
 316 overlap generally with those locations mentioned in Section 2.the last section.

317

318

319 Fig. 2. Annual number of cold condition records in northern and central China in the period  
 320 of 1733-1833 derived from REACHES database.

321 Fig. 2 shows that the annual number of cold records in northern and central China had a high  
 322 period in 1748-1751 which, if due to volcanic factor, could be associated with the Oshima-  
 323 Oshima eruption in Japan in 1741-1742 (Smithsonian Institute, 2013) but the impact would occur  
 324 many years later. The cold condition then subsided considerably for the next 35 years. Then two  
 325 very high peaks in 1786 and 1790 and a moderate peak at 1791 occurred, several years after the  
 326 Laki eruption. After that, a series of peaks occurred at 1805, 1816, and 1827, a roughly 11-year  
 327 periodicity. The timing of the 1786-1791 peaks suggests that they could be due to the volcanic  
 328 radiative forcing of Laki eruption as the impact can occur a few years after the eruption. On the  
 329 other hand, it is less certain what were responsible for the cold peaks in the 19<sup>th</sup> century.

#### 330 4. Conclusions

331 In the above, we translated several climatic records kept in Chinese historical chronicles  
332 for the 10-year period (43 – 33 BCE) after the Okmok eruption at 43 BCE recently identified  
333 (McConnell et al., 2020). These records clearly portrait a generally cold and harsh climate period  
334 that was commensurate with the negative radiative forcing expected for a volcanic eruption.  
335 Descriptions of the observed optical abnormalities of the sun and moon also match the expected  
336 consequences due to the veiling of high-altitude volcanic dusts, and the veiling might have lasted  
337 as long as 6 months. Such a long veiling period at such a long distance away from the source  
338 should indicate that the eruption must be of extraordinary magnitude as suggested in McConnell  
339 et al. (2020).

340 The precise dating of volcanic eruptions such as the studies in Gao et al. (2008) and  
341 McConnell et al. (2020) is obviously very important for identifying the cause or forcing  
342 responsible for certain past climate conditions such as the cold summer of 43 BCE recorded in  
343 the Chinese history which otherwise would always remain as a mystery. Conversely, there are  
344 many other similar climate records listed in Chinese historical documents that can be used for  
345 reconstructing past climates and their environmental impact, and when combined with new  
346 technologies such as done in Gao et al. (2008) can significantly advance our knowledge about  
347 the science of climate change (Wang et al. 2018; Lin et al. 2020).

348 **Acknowledgments.** We thank Dr. C. C. Gao and [Dr. Philip Gooding](#) for their constructive  
349 suggestions that lead to the improvement of the original manuscript. [Editorial help from Dr.](#)  
350 [Alberto Reyes is also highly appreciated.](#) This work is partially supported by National Sciences  
351 and Technology Council of Taiwan grant NSTC 112-2122-M-001-001.
