Abstract. Drought research addresses aone of the major natural hazard with adverse impacts towards achieving the sustainable development goals. Here, we analyzedhazards that threatens progress toward the Sustainable Development Goals. This study aims to map the evolution and interdisciplinarity of drought research over time and across regions, offering insights for decision-makers, researchers, and funding agencies. By analyzing more than 130,000 peer-reviewed articles indexed in

20 Scopus, spanning from 1901 to 2022 using a generative model. The results delineate latent Dirichlet Allocation (LDA) for topic modeling, we identified distinct shifts in research priorities. Plant and emerging trends. The results reveal that plant genetic research for drought-tolerant genotypes and methodadvancements in drought forecasting are the major topics with highest and still increasingmost dominant and continuously growing areas of focus. In contrast, the relative contribution to drought research. Importance of importance of topics such as ecology, groundwaterwater resource management, and forest 25 research decreases in relative terms. Untilhas decreased. Geospatial patterns highlight a universal focus on forecasting methods, with a strong secondary emphasis on policy and societal issues in Africa and Oceania. Interdisciplinarity in drought research experienced a marked decline until 1983, interdisciplinarity of drought research was steadily decreasing, marking a pivotal shift, followed by a consistent rise in interdisciplinaritysteady increase from 2007 onwards. Geospatial patterns reveal a focus on forecasting methodsonward, suggesting a growing integration of diverse fields. Emerging topics in all regions, and 30 particular focus on policy and society in Africa and Oceania. In recent years signal evolving priorities for future, we recommend research and funding agencies to strengthen the track of more interdisciplinary and systemic cross topic-. This analysis provides a comprehensive overview of drought research in order to cope with drought as a multi-sectoral risk requiring multi-sectoral response frameworks,trends across sectors and regions, offering strategic guidance for aligning research efforts

with drought resilience goals. The findings are crucial for research funding agencies and policymakers aiming to prioritize areas with the highest potential to mitigate drought impacts effectively.

1 Introduction

Drought is one of the socio-economically most damaging natural hazards (Yin et al., 2023; Esha Zaveri et al., 2023). Contrary to other climate extremes, drought manifests on a vast spatiotemporal scale, extending up to thousands of kilometers, and can persist for periods lasting up to years (Mondal et al., 2023). Drought episodes are becoming increasingly frequent, extreme, and prolonged driven by climate change (Hoylman et al., 2022; IPCC, 2021). Drought is significantly tied with other climate-driven hazards, particularly heatwaves, which can amplify drought impacts (Lesk et al., 2022). The emergence of frequent flash droughts in over 74% of the globe during the last 64 years has been also recently revealed (Yuan et al., 2023). This pattern is largely linked to elevated anomalies in evapotranspiration and precipitation deficits which are confirmed consequences of human induced climate change (Yuan et al., 2023). Drought as the state of water shortage is exacerbated by anthropogenic activities such as unsustainable water use, allocation and water extraction (van Loon et al., 2022; van Loon et al., 2016; Chiang et al., 2021). This led to the reconsideration of the definition of drought as rather a being a process than a system state (van Loon et al., 2016; AghaKouchak et al., 2021). Drought poses therefore a substantial risk for and across sectors and systems (Voosen, 2020; Walker and van Loon, 2023; Hagenlocher et al., 2023), including agriculture, water supply, health, the energy sector, ecosystem services, and socio-political stability. Drought is one of the socio-economically most damaging natural hazards (Yin et al., 2023; Esha Zaveri et al., 2023). Contrary to other climate extremes, drought manifests on a vast spatiotemporal scale, extending up to thousands of kilometers, and can persist for periods lasting up to years (Mondal et al., 2023). Drought episodes are becoming increasingly frequent, extreme, and prolonged driven by climate change (Hoylman et al., 2022; IPCC, 2021). Drought as the state of water shortage is exacerbated by anthropogenic activities such as unsustainable water use, allocation and water extraction (van Loon et al., 2022; van Loon et al., 2016a; Chiang et al., 2021). This led to the reconsideration of the definition of drought as rather a being a process than a system state (van Loon et al., 2016a; AghaKouchak et al., 2021; van Loon et al., 2024). Drought poses therefore a substantial risk for and across sectors and systems (Voosen, 2020; Walker and van Loon, 2023; Hagenlocher et al., 2023), including agriculture, water supply, health, the energy sector, ecosystem services, and socio-political stability.

65

55 Drought impacts ecosystems by modifying ecological processes, altering of community structures and composition (Canarini et al., 2021). These changes can lead to adaptations such as improved water use efficiency in response to water storage(Poppe Terán et al., 2023). The total land area and population affected by severe terrestrial water storage drought could more than

70 double by the end of the twenty-first century (Pokhrel et al., 2021). Over the first twenty years of the 21st century, extreme drought and drinking water shortages have plagued more than 80 major cities worldwide (Savelli et al., 2023). Food production and security have already been largely compromised by drought (Spinoni et al., 2020; Rossi L et al., 2023). For instance, the size of the dry zones across the global grain production area increased by 1.1 % per decade in the period from 1951 to 2011 (Wang et al., 2018). Globally, the average national cereal production shrank by 10 % over the period 1964 to 2007 as a result

75 of extreme drought and heat (Lesk et al., 2016). In Europe, the adverse impacts of droughts and heatwaves on crop production tripled in the last 50 years Drought impacts ecosystems by modifying ecological processes, altering of community structures and composition (Canarini et al., 2021). These changes can lead to adaptations such as improved water use efficiency in response to water storage(Poppe Terán et al., 2023). ▲ Without climate action, annual drought damages for the EU and the UK could escalate from €9 billion to over €65 billion per year by 2100, doubling in terms of financial impact (Naumann et al., 2021). Given the potential damage caused by drought, it is crucial to conceptualize, develop, plan, implement, monitor, and assess effective sustainable adaptation strategies for the benefit of society at large. Exploring the long term research timeline for drought enables the research community, funding bodies, and policymakers to more effectively align their efforts, prioritize resources, and design strategies aimed at mitigating adverse impacts, enhancing resilience, and supporting sustainable adaptation to escalating drought events.

90 Without climate action, annual drought damages for the EU and the UK could escalate from €9 billion to over €65 billion per year by 2100, doubling in terms of financial impact (Naumann et al., 2021). Drought also impacts human health (Vins et al., 2015) e.g. through reducing stream flow, increasing concentration of pathogens, enabling some vector-borne diseases (Cann et al., 2013) and as risk factor of child undernutrition in particular in low-income conditions (Belesova et al., 2019). The impacts of drought are scale specific, event specific and often difficult to quantify due to their indirect and often systemic character - affecting not only human health and agriculture but also energy and social systems (van Loon et al., 2019; Blauth et al., 2015).

100

This study is motivated by the need to enhance our understanding of the evolving landscape of drought research, particularly in light of the escalating challenges posed by climate change and water scarcity. While previous reviews outlined the need to synthesize the immense body of literature on drought research (Stein et al., 2022), our analysis distinguishes itself through the use of a data-driven, unsupervised machine learning approach to examine over 130,000 peer-reviewed articles. By exploring long-term research trends, we identify critical shifts in thematic focus, fundamental and emerging trends, and interdisciplinary collaboration opportunities that have shaped the field. This unique approach allows us to reveal previously overlooked patterns and gaps in the literature, offering insights into how research priorities have been set by the global research communities. Our findings contribute to the development of more effective and systemic drought resilience frameworks by quantifying the connections between diverse research topics, ultimately guiding more strategic alignment of efforts among scientists, funding bodies, and policymakers.

2 Methods

We based the analysis on 131,748 abstracts curated in the licensed Scopus database under the search term drought on March 22, 2023. Data on title, keywords, language, abstract and publication year were retrieved from the Scopus database via the Scopus Search API and the elaspy search library. We removed duplicates, copyright information and non-English abstracts. Scopus provides the largest curated database of scientific literature and grants access to data- and text mining to licensed users for academic purpose. To discern pertinent topics and subtopics within the dataset, we used the latent Dirichlet Allocation (LDA) (Blei et al., 2003; Radim Rehurek and Petr Sojka, 2010) method. LDA, an iterative Bayesian method of unsupervised machine learning, identifies multiple topic clusters within documents based on keyword distribution, co-occurrence, and frequency. Depending on the chosen granularity, classification can yield either broad or highly specific topics. Remarkably, while LDA is a well-established method (Eker et al., 2018; Ewert et al., 2023; Cebral Loureda et al., 2023; Rahman et al., 2022), its application to vast scientific abstract corpora is rare. To explore the drought research areas, we identified rather general topics and more specific topics. This was done by pre-defining the number of topics to the algorithm and LDA did cluster the documents based on keywords into the given number of topics. We assessed coherence scores for a consecutively increasing number of topics, found that coherence increases until fifty topics, and decided to cap granularity at fifty topics, which would still yield 2634 documents on average per topic. We then selected five topics as a reasonable number for the general classification level, and twelve topics for a median level of granularity and fifty topics for the finest level granularity. Naming conventions for topics were derived from pivotal keywords within the context of drought research. To evaluate the evolving significance of research themes over time, we charted relative shares of each topic annually. For topic congruence, we calculated the cosine similarity between topic pairs. Cosine similarity normalizes the similarity score by the overall share of the two topics. This allows for a better direct comparison for topics with high shares and those with low shares. Here, a high

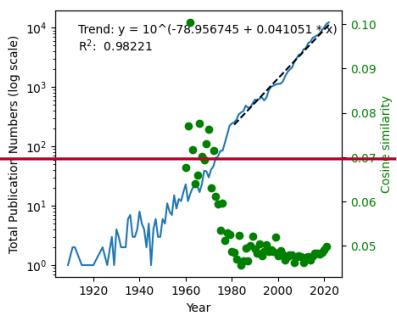

similarity score indicates that two topics appear more frequently together in the same document. A low similarity score indicates lesser joint appearance. Topical overall similarity index is calculated as mean cosine similarity of a topic for the other $n-1$ topics. Heat maps of cosine similarity are ranked by overall similarity score of a topic starting with the highest to lowest.

135 We visualized the topic trajectory using a Sankey diagram to highlight how general topics with coarse granularity narrow down to more specific topics. Consistent with Sankey diagrams, the width of the connecting lines is proportional to the document counts they represent. The geographic reference of drought research to individual continents was identified by keyword search. Abstracts were associated to a region i.e. continent, or country (for the US also the states) was mentioned in the title, keyword or abstract. One document could be associated with several regions in case several 140 mentions. Topical shares by region were then calculated based on the documents found.

3 Results

3.1 Major and specific topics in drought research

Here, we employed a generative statistical model (Latent Dirichlet Allocation (Blei et al., 2003; Radim Rehurek and Petr 145 Sojka, 2010) [LDA]), to assess 131,748 peer-reviewed articles revealing changes in the patterns of drought related topics indexed in Scopus from 1901 up to the present. LDA enabled us to capture heterogeneity within research topics, using an unsupervised machine learning approach to reveal latent topics from linguistic data (Eker et al., 2018; Ewert et al., 2023). The number of drought related peer-reviewed publications has increased exponentially adding 12,338 articles in 2022 alone (Figure 150 1). We let the LDA identify five major topics across the document pool (tier 1), twelve more focused yet still rather general topics (tier 2) and fifty even more specific topics (tier 3, Figure 2). While keyword frequency and co-occurrence generate topic clusters, they also allow domain experts to name the topics according to their context. A list of publications with the highest share of each topic (i.e. topical relevance $> 98\%$) confirms the topic naming.

155 **2.1 Data**

We based the analysis on 131,748 abstracts curated in the licensed Scopus database under the search term drought on March 22, 2023. Data on title, keywords, language, abstract and publication year were retrieved from the Scopus database via the Scopus Search API and the elaspy search library. We removed duplicates, copyright information and non-English abstracts. Scopus provides the a curated database of scientific literature and grants access to data- and text mining to licensed users for academic purpose. The following alternative large databases for meta-information of scientific literature were considered: OpenAlex, Web of Science, Dimensions and Semantic Scholars. We chose Scopus because of its high quality of information and granted access for research purpose.

160 **2.2 Topic Modelling by Unsupervised Machine Learning**

To discern pertinent topics and subtopics within the dataset, we used the Latent Dirichlet Allocation (LDA) (Blei et al., 2003; Radim Rehurek and Petr Sojka, 2010) method. LDA, an iterative Bayesian method of unsupervised machine learning, identifies multiple topic clusters within documents based on keyword distribution, co-occurrence, and frequency. Depending on the chosen granularity, classification can yield either broad or highly-specific topics. Remarkably, while LDA is an established method (Eker et al., 2018; Ewert et al., 2023; Cebral-Loureda et al., 2023; Rahman et al., 2022; Callaghan et al., 2020), its application to vast scientific abstract corpora is rare. Compared to other alternatives, LDA allows for multiple topics within a single document. Also, LDA represents a compromise between computationally more expensive and more costly topic modelling approaches such as BERTTopic (Ogunleye et al., 2023), and simpler and computationally less expensive approaches such as Latent Semantic Analysis (Deerwester et al., 1990). To explore the drought research areas, we identified rather general topics and more specific topics. This was done by pre-defining the number of topics to the algorithm. We then calculated topic distributions with LDA for the documents and for given number of topics based on overall and document specific keyword distributions. We assessed coherence scores for a consecutively increasing number of topics, found that coherence increases until fifty topics, and decided to cap granularity at fifty topics, which would still yield 2634 documents on average per topic. We then selected five topics as a reasonable number for the general classification level, twelve topics for a median level of granularity and fifty topics for the finest level granularity (see results Section Figure 2). Naming conventions for topics were derived from pivotal keywords within the context of drought research. To evaluate the evolving significance of research themes over time, we charted relative shares of each topic annually.

175 **2.3 Data Post-Processing**

For topic congruence, we calculated the cosine similarity between topic pairs within each individual document. A high similarity score indicates that two topics appear more frequently together in the same document. A low similarity score indicates lesser joint appearance. Cosine similarity normalizes the similarity score by the overall share of the two topics. This allows for a better direct comparison for topics with high shares and those with low shares. Topical overall similarity index is

calculated as mean cosine similarity of a topic for the other n-1 topics. Heat maps of cosine similarity are ranked by overall similarity score of a topic starting with the highest to lowest. We visualized the topic trajectory using a Sankey diagram to highlight how general topics with coarse granularity narrow down to more specific topics. Consistent with Sankey diagrams, the width of the connecting lines is proportional to the document counts they represent. The geographic reference of drought

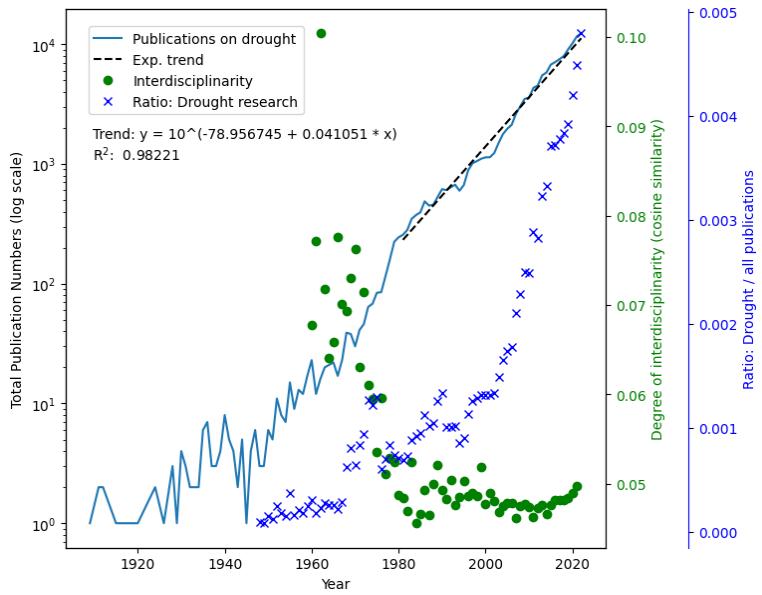

190 research to individual continents was identified by keyword search. Abstracts were associated to a region i.e. continent if a specific continent, or country (for the US also the states) was mentioned in the title, keyword or abstract. One document could be associated with several regions in case several mentions. Topical shares by region were then calculated based on the documents found.

195 **3 Results**

3.1 Major and specific topics in drought research

The number of drought-related peer-reviewed publications has increased exponentially adding 12,338 articles in 2022 alone (Figure 1). The proportion of articles focussing on drought increases year by year compared to the general scientific literature. This is expressed by the ratio of drought related research compared to the available scientific publications in webofscience

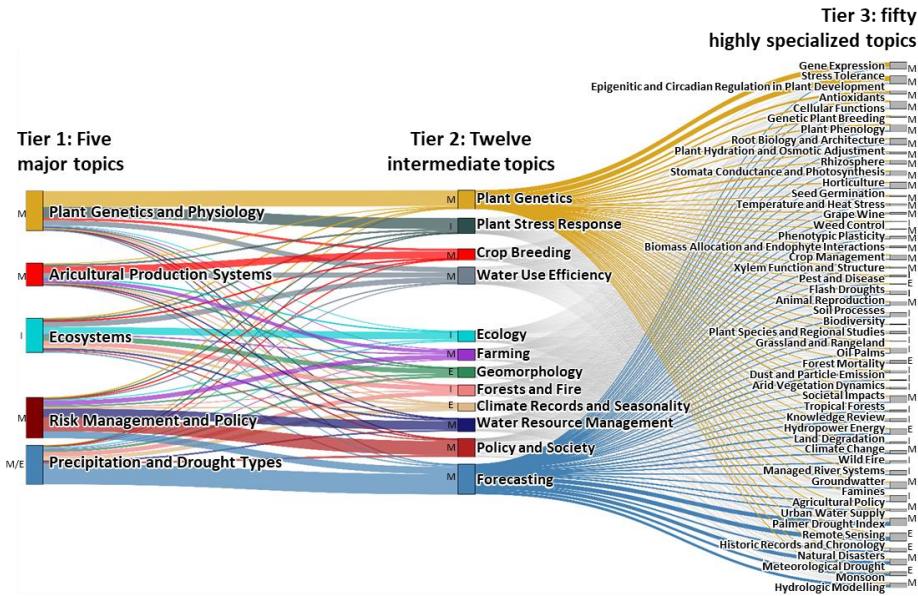

200 (Figure 1). We let the LDA identify five major topics across the document pool (tier 1), twelve more focused yet still rather general topics (tier 2) and fifty even more specific topics (tier 3, Figure 2). While keyword frequency and co-occurrence generate topic clusters, they also allow domain experts to name the topics according to their context. A list of publications with the highest share of each topic (i.e. topical relevance > 98%) confirms the topic naming.

205

Figure 1: Publications by year in drought research. Research abstracts listed in Scopus and analyzed over the past century with regard to interdisciplinarity. Drought research exhibits an exponential trend ($R^2 = 0.98$). This trend is highlighted by the increasing ratio of drought research to overall research publications. Interdisciplinarity is calculated as cosine similarity index which is the normalized cross-topic intersection within a document. Focus on range of specific topics increased until 1980s when which is marked by a decline in interdisciplinarity. 1980 onwards plant genetics took a rise, leading to ups and downs in interdisciplinarity. From 2007 onwards inter-disciplinary rose again consistently.

210

215
220
Figure 2: Hierarchical Depth of Research Topics in Drought Research. The breadth of drought research encompasses a diverse array of subjects. Each column represents the entire research corpus, encompassing 131,748 articles. This figure displays the share of each topic against the whole corpus. Three levels of specificity are distinguished: five broad topics (left), twelve intermediate topics (center), and fifty highly specialized topics (right). Visual emphasis is placed on the flows of plant genetics and forecasting, given their upward trends and dominance in the research field. Line width and width of bars is proportional to the share per topic. Topics are categorized into methods and processes (M), events and historical analysis (E), and impacts on socio-ecosystem compartments (I). For high resolution interactive Figure, please see the Supplement Figure S1.

Formatiert: Schriftart: 9 Pt.

225
The five general topics were categorized as *plant genetics and physiology*, *agricultural production systems*, *ecosystems*, *risk management and policy*, and *precipitation and drought types*. At the medium granularity with 42-twelve topic classification, we identified *forecasting* methods including drought types and events on the one end and *plant genetics* at the other end as most dominant research topics. For the twelve topic classification, a network graph visualizes the connections of topics and keywords (Figure 3). Here, the dataset's structure is visualized with limited number of most important keywords in two dimensional space. As a result of the LDA, and topical distribution, *forecasting* is mainly associated to *risk management and*

230 *policy and precipitation and drought types* from tier 1, with lesser association to the other three topics of tier 1 (Figure 2). This reflects how *forecasting* focuses on answering questions on risk using quantitative methods. In contrast, *water use efficiency* is strongly associated with three topics of tier 1, reflecting a higher transdisciplinarity and positioning it at the intersection of natural *ecosystems*, *agriculture* and *plant physiology*. *Farming*, as tier 2 topic, is particularly interesting as it bridges the gap through its strong association to *risk* and *agricultural production systems* (Figure 2). Other topics at level two are
235 *geomorphology*, *forests and fire*, *climate records and seasonality*, *groundwater*, *water resource management*, and *policy and society* (Figure 3).

240

Figure 3: Network graph of drought research. Visualizes the network of the twelve drought research topics. Colors denote topics with strongest association, bubble size identifies abundance of keywords, keywords are located below the bubbles, links between keywords identify strongest co-occurrences, and keywords are located in order to minimize connection lengths. For high resolution figure, please see the Supplement Figure S2.

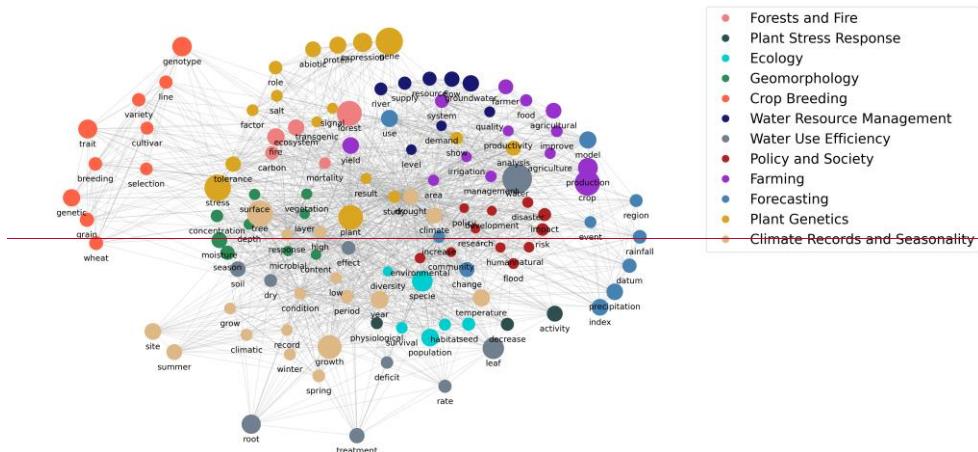

245

Formatiert: Schriftart: 9 Pt.

Topic identification and naming at the finest granularity reveal 50 specialized, potentially emerging topics, with an average of 2634 papers per topic. In the Sankey diagram, for these fifty topics, shares by topic ranged between 134 documents and 5901 documents with a median of 2337 documents. In the Sankey diagram (Figure 2), the association of Tier 3 topics with Tier 2
250 topics is indicated by a) their vertical alignment and b) the strength of the links. The topics *gene expression* and *stress tolerance* are at the top, with a strong link to *plant genetics*. At the bottom of Figure 2, the topics *monsoon* and *hydrologic modelling*

have a strong link to *forecasting*. These results quantify the extent, importance and the role of **specific** research topics with respect to drought research. The results demonstrate the importance to render and limit the topical scopes of reviews.

Formatiert: Block, Zeilenabstand: 1,5 Zeilen

255

Other categorizations and classifications are possible. For example, research can be grouped into publications focussing on the analysis of methods and processes, of events and historical analysis, and impacts on socio-ecosystem compartments. Method Figure 3: Network graph of drought research. Visualizes the network of the twelve drought research topics. Colors denote topics with strongest association, bubble size identifies abundance of keywords, keywords are located below the bubbles, links between keywords identify strongest co-occurrences, and keywords are located in order to minimize connection lengths. Formatiert: Schriftart: 9 Pt.

260

Topics for instances strongly associated to forecasting methods can be grouped into studies with a focus on methods (e.g. remote sensing, hydrologic modelling, meteorological drought) and on events (e.g. historic drought records and chronology, monsoon (Figure 2). Here, method related research focuses on processes, tools, and methods for adaptation and mitigation of drought. Event studies focus on specific event types and historical analysis to guide development of methods. In addition, many topics Topics focussing on impact mostly focus on impacts of drought on a specific socio-ecosystem compartment Following this categorization, within the tier 3 specific topics in the lower half of the Sankey diagram method with a strong link to forecasting can be grouped for example into methods related topics are (e.g. remote sensing, hydrologic modelling, remote sensing, agricultural policy, managed river systems, meteorological drought) and knowledge review events related topics (e.g. historic drought records and chronology, monsoon (Figure 2). In the upper half, tier 3 topics that focus on methods are e.g. improving gene expression, stress tolerance, epigenetic and circadian regulation in plant development, genetic plant breeding, adapting plant phenology. Impact related topics, from top to bottom, include

Formatiert: Schriftart: Kursiv

Formatiert: Schriftart: Kursiv

grape wine, pest and disease, animal reproduction, biodiversity, grassland and rangeland, oil palms, forest mortality (Figure

275 2). Event-type tier 3 topics, from top to bottom, include *flash droughts, dust and particle emission, natural disasters, etc.*) The density of method-related topics is much higher in the areas of *plant genetics, physiology, and agricultural management* than in forecasting-related topics. Impact-related topics for tier 3 are mostly found in the center, while topics related to events are predominantly situated in the lower section. This categorization was assessed for tier 1 and tier 2 topics. (Figure 2). The results highlight a significant interconnection between research on events, impacts, and methods. This interplay, however, sometimes 280 leads to challenges in distinctly categorizing topics, as evidenced by occasional overlaps and blurred boundaries among these areas (Figure 2).categories.

Formatiert: Schriftart: Kursiv

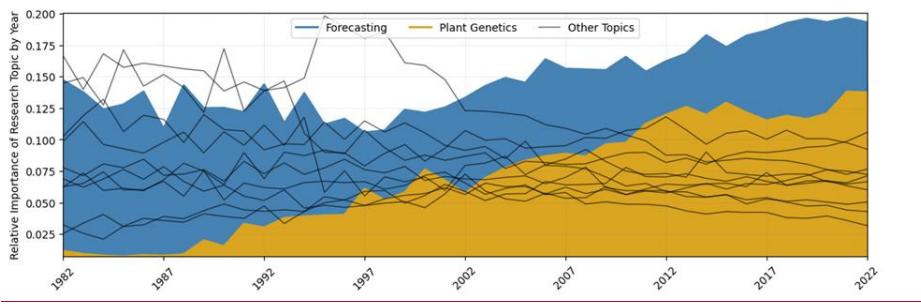

Formatiert: Schriftart: Kursiv

3.2 General and emerging trends

Interest in research topics fluctuates over time. Shifts in research priorities are influenced by societal interest and advancements

285 in technological capabilities. We explored the development over time for drought-related research topics and their relative contributions over the past four decades (Figure 4) and more recently, referring to the years 2012-2022. We chose the last four decades because the data showed a rather high variation in relative contributions for the year before 1982. *Plant genetics and forecasting* as well as *crop breeding* are getting an increasing relative share of the research over the last four decades (Figure 4 and Appendix Figure B). *Ecology* and *water use efficiency* have received comparatively less attention with declining shares. 290 Surprisingly, *water use efficiency* is not the specific aim of *plant genetics* and *crop breeding* efforts but rather stands next to these in tier 2. Crop scientists have long targeted drought-tolerant crops to tackle food production challenges in dry regions. The introduction of new genomic technologies has greatly enhanced this effort (Anders et al., 2021), a trend reflected in our analysis. Amongst *plant genetic* and *plant breeding*, specific research on cellular and molecular functions exhibit positive trends for recent years such as the *epigenetic and circadian regulation in plant development* or the role of *antioxidants* that 295 may reduce oxidative damage during drought stress (Bailey-Serres et al., 2019). Plant physiological processes such as *plant phenology* and *stomata conductance* and *photosynthesis* recently became less relevant although strongly related to *plant genetics* and *plant breeding*.

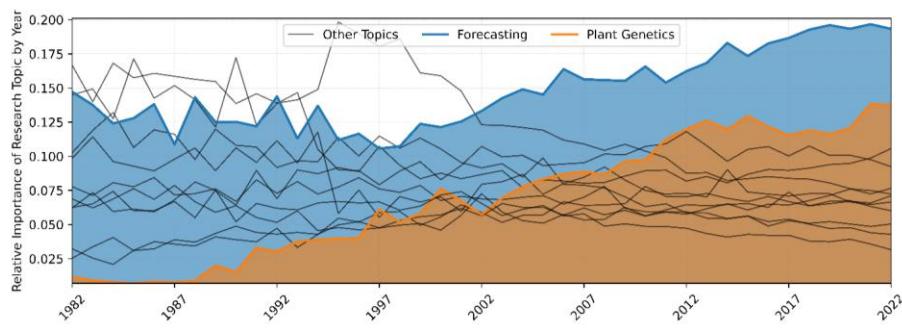

300 Despite the rise in machine learning approaches being applied for drought forecasting (Al Mamun et al., 2024; Prodhan et al., 2022), in this analysis machine learning and artificial intelligence were not identified as individual topics. In addition, early warning systems and compound events were not identified as distinctive topics although urgency for progress in these topics is perceived as high (FAO-WFP early warning analysis of acute food insecurity hotspots, 2020; Yin et al., 2023; Ridder et al., 2022). There are two possible reasons for this. Firstly, these topics have not emerged as distinct individual topics within drought research and are potentially well distributed across the research domain. Secondly, the fraction of research on these topics was 305 too small to result in an individual cluster.

3.21.1 General and emerging trends

Interest in research topics fluctuates over time. Shifts in research priorities are influenced by societal interest and advancements 310 in technological capabilities. We explored the development over time for drought related research topics and their relative contributions over the past four decades and more recently, referring to the years 2012–2022. *Plant genetics* and *forecasting* as well as *crop breeding* are getting an increasing relative share of the research over the last four decades (Figure 4 and Supplement Fig. A). *Ecology* and *water use efficiency* have received comparatively less attention with declining shares. Surprisingly, *water use efficiency* is not the specific aim of *plant genetics* and *crop breeding* efforts but rather stands next to 315 these in tier 2. Crop scientists have long targeted drought tolerant crops to tackle food production challenges in dry regions. The introduction of new genomic technologies has greatly enhanced this effort (Anders et al., 2021), a trend reflected in our analysis. Amongst *plant genetic* and *plant breeding*, specific research on cellular and molecular functions exhibit positive trends for recent years such as the *epigenetic* and *circadian regulation in plant development* or the role of *antioxidants* that may reduce oxidative damage during drought stress (Bailey-Serres et al., 2019). Plant physiological processes such as *plant* 320 *phenology* and *stomata conductance* and *photosynthesis* recently became less relevant although strongly related to *plant*

genetics and plant breeding. Hence, future yield projections under climate change scenarios for food security should expect and incorporate biological advances in plant's genetic and molecular functions to become more drought tolerant.

325 **Figure 4: Temporal Dynamics of Research Topics.** The evolution of research topics and their proportionate dominance
326 from 1982 onwards, highlighting the ascendance of plant genetics and forecasting as dominant trending topics. For
327 high resolution Figure, please see the **Supplement Figure S3**.

Formatiert: Schriftart: 10 Pt.

Formatiert: Schriftart: Fett

330 Other tier 2 topics, such as *groundwater*, *water resource management*, *geomorphology*, *policy and society*, have also
331 demonstrated a generally declining relative contribution to drought research over the last 40 years (Figure 4 and **Supplementary**
332 **Fig. A**). It is vital to clarify that the decrease in relative share for e.g. *ecology* or *groundwater* topics does not imply a decrease
333 in the absolute number of research studies on these subjects. Instead, the number of documents on these topics continues to
334 grow, but the rate of growth was comparatively slower (Supplement Fig. B). In tier 2, *forecasting* methods and events
335 represented the largest contribution among all topics across the study period (Figure 3). The urgent need for better drought
336 preparedness through accurate forecasting based on mechanism understanding, coupled with the pressing demand to maintain
337 food security for a growing population under more frequent drought conditions, may be the primary reason for the increase in
338 the share of drought-related research in these domains (Krishnamurthy R et al., 2022). The emergence of fast developing
339 drought events may also be another factor to explain such increase together with the occurrence of temporally persistent and
340 large scale events (e.g. in the La Plata basin in South America, in west Africa) (Geirinhas et al., 2023). *Meteorological drought*,
341 *remote sensing*, *climate change*, *natural disasters* and *palmer drought index* are emerging topics with strong association to
342 *forecasting*. Given the stark data requirement, need for data integration platforms, environmental monitoring systems and
343 artificial intelligence as method for generating indices, these may be important factors behind the growing importance of
344 drought *forecasting* (Wardlow et al., 2017; Pasteris et al., 2005).

345 **3.3 — Interdisciplinarity of drought research**

Each document consists of a variety of topics expressed as percentage i.e. share with the total sum of one for each document. While the algorithm for topic identification aims to discern individual topics within the corpus, the major share of a specific topic may dominate a specific document. In another case the topical shares may be dispersed across many topics. We measure interdisciplinarity by cosine similarity, a measure for similarity between two topics and a measure that scales well with the size of the two topics. We find for tier 2 topics (and Appendix Figure B). It is vital to clarify that the decrease in relative share for e.g. *ecology* or *water resource management* topics does not imply a decrease in the absolute number of research studies on these subjects. Instead, the number of documents on these topics continues to grow, but the rate of growth was comparatively slower (Appendix Figure A). In tier 2, *forecasting* methods and events represented the largest contribution among all topics across the study period (Figure 3).

355

Looking at Tier 3 topics, we identified the top 10 emerging topics. *Meteorological drought, remote sensing, climate change, natural disasters and palmer drought index* are the five emerging topics with strong association to *forecasting*. *Antioxidants, Epigenetic and circadian regulation in plant development, and gene expression* are the three emerging topics with strong link to *plant genetics*. *Agricultural policy and rhizosphere* are also amongst the ten emerging topics. Here, *agricultural policy* is strongly associated to *policy and society*. Interestingly, *rhizosphere* is the only topic of these with rather evenly strong links to many of the Tier 2 topics.

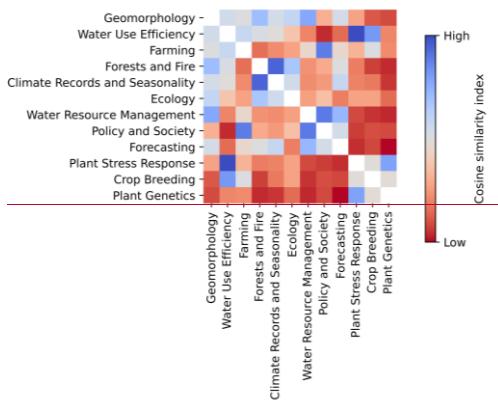

360 **3.3 Interdisciplinarity of drought research**

Each document consists of a variety of topics expressed as percentage i.e. share with the total sum of one for each document.

365 While the algorithm for topic identification aims to discern individual topics within the corpus, the major share of a specific topic may dominate a specific document. In another case the topical shares may be dispersed across many topics. We measure interdisciplinarity by cosine similarity, a measure for similarity between two topics and a measure that scales well with the size of the two topics. We find for tier 2 topics (Figure 5) several robust thematic overlaps. For example, *Plant stress response and water use efficiency* showed the highest thematic overlap. Also, *climate records and seasonality* are strongly manifested in sedimentary records and tree ring records, causing a high similarity with *forests and fire*. Pronounced similarity is also found between *policy and society* with the topics *farming* and *water resource management* (Figure 5). Here, *water resource management* which is crucial for fresh water supply and energy systems (Jasechko et al., 2024) as well as for irrigation and food security has strong impact and link to *policy and society* (Figure 5).

370 375 In contrast, *forecasting* is rather focusing on short-term responses with less pronounced similarities. → several robust thematic overlaps. *Plant stress response* and *water use efficiency* showed the highest thematic overlap. *Climate records and seasonality*

are strongly manifested in sedimentary records and tree ring records, which causes a strong similarity of both tier 2 topics. Also pronounced similarity is found between *policy and society* with the topics *farming* and *groundwater* (Figure 5). Here, groundwater which is crucial for fresh water supply and energy systems (Jasechko et al., 2024) as well as for irrigation and food security has strong impact and link to *policy and society*. Surprisingly, *geomorphology* and *water use efficiency* possess highest overall interdisciplinarity, indicating that these are generally important topics with impact across most drought research topics (Figure 5). In contrast, *forecasting* is rather focusing on short term responses with less pronounced similarities. Surprisingly, *geomorphology* and *water use efficiency* possess highest interdisciplinarity, indicating that these are generally important topics with impact across most drought research topics (Figure 5 and Figure 2). For example, research where *geomorphology* and *water use efficiency* well overlap focus on soil processes, soil formation and impacts on plant water uptake as well as irrigation. In contrast, *plant genetics* and *crop breeding*, jointly with *plant stress response* are less interdisciplinary with some similarities amongst each other. In this context, *forecasting* is only marginally linked to these three topics (Figure 5 and Figure 2).

380

385

390

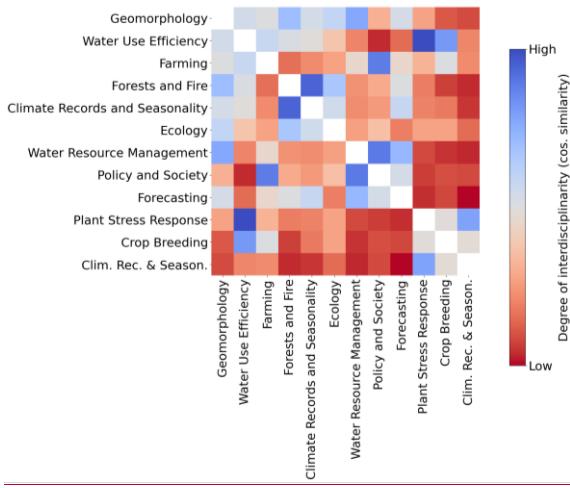

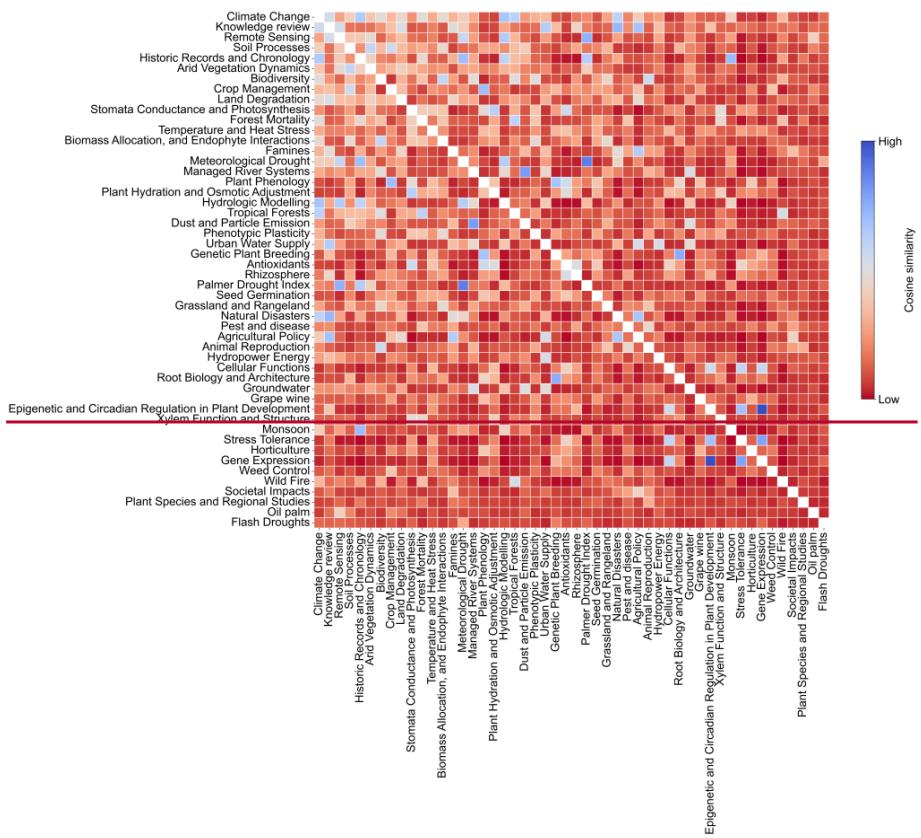

Figure 5: Thematic Overlap of Research Topics. Cosine similarity shows strength of overlaps between topics. It is the topic-wise similarity score that is the numerical value for cross-topic intersection. Stronger thematic overlaps (e.g., plant genetics and plant stress response) are identified by higher similarity, while minimal similarity score also stands for minimal intersections between two topics (e.g., plant genetics and forests and fire). Topics are sorted from highest overall similarity score (geomorphology) to lowest overall similarity score (plant genetics).

395

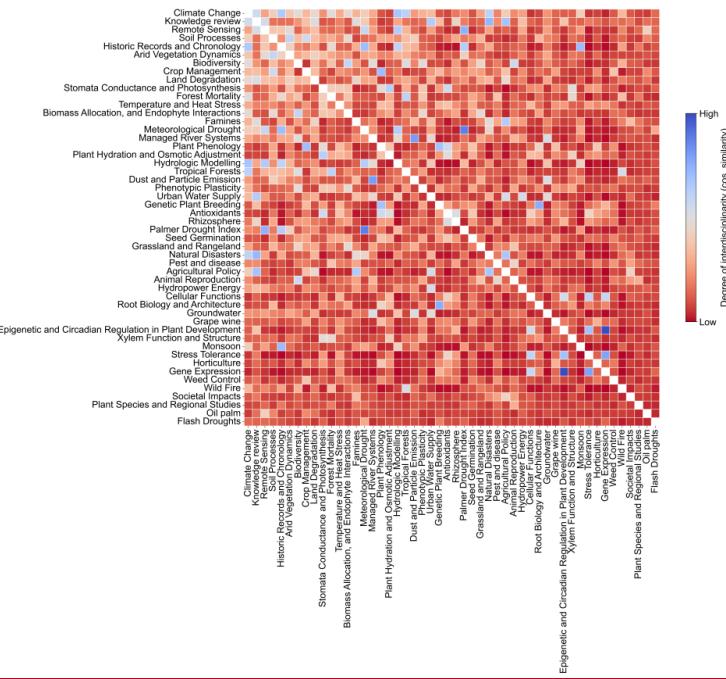

More specific topics of tier 3 reveal a different picture regarding inter-disciplinarity (Figure 6). These topics are more specific
 400 than the tier 2 topics. Here, *climate change*, *knowledge review*, *remote sensing* and *soil processes* lead the field in terms of overall interdisciplinarity (Figure 6). We note that these topics are highly inter-disciplinary based on the topical analysis results. *Knowledge reviews* seems to not only review a specific topic but make inter-connections beyond single topics. *Climate change* does relate to several topics e.g. through cause and impact. *Soil processes* affect a large number of fields apart from the mere research topic of its own. The same for *remote sensing* albeit here, with emphasis on two specific topics: *Meteorological* and
 405 *Palmer drought index* which themselves also possess a high similarity index (Figure 6). In contrast to interdisciplinary topics, *flash droughts*, *oil palm*, and *plant species and regional studies* are rather narrow in scope with low overall interdisciplinarity within drought research (Figure 6). Cosine similarity highlights further topics with strong similarity while for other topics we identify major difference and little overlap in terms of content. Here, interdisciplinarity appears to be more challenging rather than an opportunity to form larger content clusters. **We urge researchers who work on narrow, very specific topics – albeit**
 410 **important topics such as *flash droughts* and *plant species and regional studies* to expand on interdisciplinarity, and outline impacts in and relations to other areas.**

Formatiert: Schriftart: Nicht Fett

Formatiert: Standard, Tabstopps: Nicht an 0 cm

415 **Figure 6: Thematic Overlap of Research Topics** the fifty highly specialized research topics. Overlap of the 50-topic clustering results is based on the cosine similarity between topics as metric for similarity and inter-disciplinarity (high to low). The vertical axis is sorted for highest to lowest overall similarity score. Highest overall similarity score was calculated for climate change and knowledge review. Some topics such as gene expression exhibit very low overall similarity score marked by mostly dark red although there can be at times a strong relation to individual topics (dark blue) for instance gene expression and epigenetic and circadian regulation in plant development.

420

The multi-system impact of drought as natural hazard challenges the often topic specific approach of research projects by requiring a multi-system response. The trend-shift in 2007 towards drought research becoming more systemic again may 425 acknowledge this multi-system property of drought hazard, exposure and vulnerability. Until 2007, drought research evolved to become more disciplinary as explained by the annual similarity index (Figure 1). Notable trend shifts occurred in the 1980s when genetics was introduced into drought research and started to become a major topic in the 30 years following. This led to a first trend shift from becoming more disciplinary by 1983 to again becoming more interdisciplinary with high volatility throughout. The second trend shift happened in the years around 2007, when similarity was lowest and succeeded again from

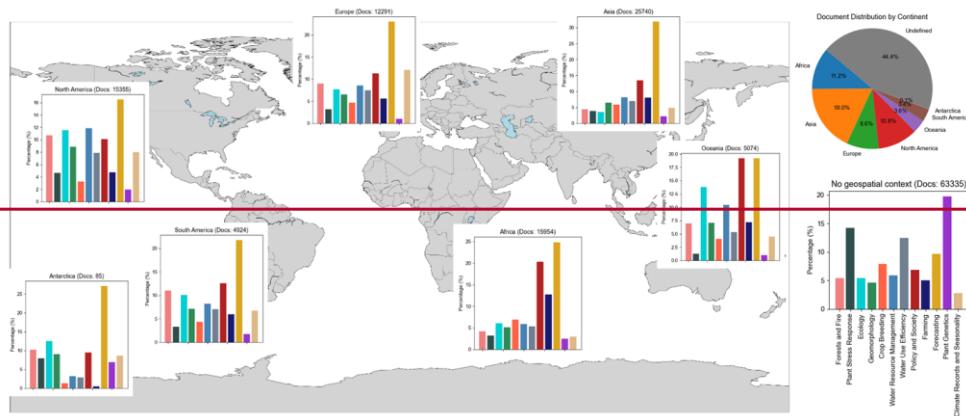

Formatiert: Schriftart: Nicht Fett, Hervorheben

Formatiert: Standard, Tabstopps: Nicht an 0 cm

430 a stable upward trend. Noting the systemic impact of drought, we welcome the trend of drought research to become more interdisciplinary because only systemic approaches can properly enhance drought impact resilience across systems.

3.4 Geographic patterns and priorities

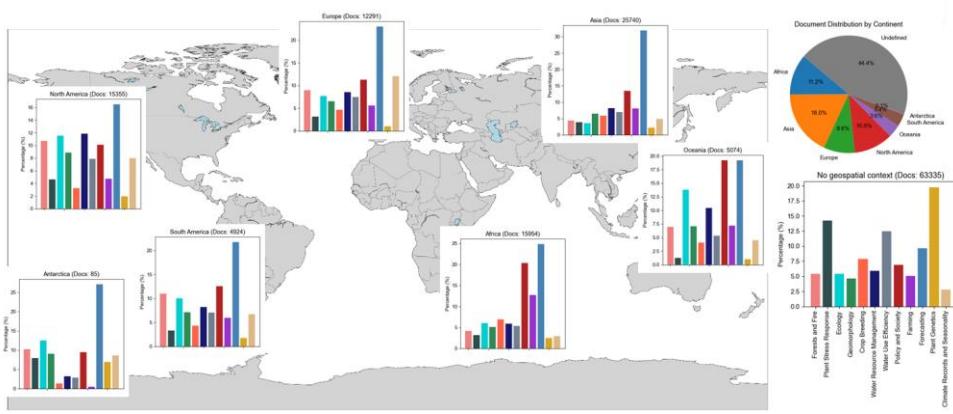

435 Research priorities vary with regard to geographic context. We analyzed continent specific topical signatures in drought research (Figure 7). The largest number of studies refers to Asian (18.0%) and African countries (11.2%) although research budgets in Europe and North America are generally higher than in Africa. This indicates that drought is well recognized as challenge to many African countries, even more so in Asia. As major pattern, forecasting dominates drought research in 440 geospatial context in all regions. In Africa and Oceania, *forecasting* is closely followed by research on *policy and society*. This pattern is less pronounced for Europe, Asia and South America (Figure 7). In Africa, *farming* is the third largest topic with still 12.5 percent and the other topics are less relevant. North American drought research prioritizes *groundwater*, *water resource management*, *ecology* and *forests and fire*, just after *forecasting* with less weight on *policy and society* as compared to the other regions. In Oceania and Antarctica, *ecology* is the third major topic. Although there are distinct regional differences amongst the geographic regions, the Southern and Northern hemisphere do not show distinct topical patterns (Figure 7). *Forecasting*, and *policy and society* are the two major topics with geospatial context. *Plant genetics* is the major topic for 445 research with no geospatial context, just before *plant stress response* and *water use efficiency*, due to the focus on biological, physiological, genetic and molecular scales.

4 Discussion

460 This study analyzed over 130,000 peer-reviewed articles on drought research published between 1901 and 2022, identifying key trends, emerging topics, and interdisciplinary shifts within the field. The analysis revealed that drought research has undergone significant transformations, with increasing attention to plant genetics and forecasting methods, while traditional areas like ecology, water resource management, and forestry have seen a relative decline. Regional analysis showed that forecasting methods are a dominant focus globally, whereas policy and societal dimensions play a particularly important role in Africa and Oceania. Furthermore, interdisciplinarity in drought research decreased until 1983, followed by a rise from 2007
 465 onwards, signaling a growing trend toward more integrative approaches. These findings provide a foundation for evaluating the evolving priorities in drought research and their implications for addressing drought risk in diverse contexts.

4.1 Definition and use of drought in literature

470 An important aspect of analyzing the results is understanding the definition, mention, and meaning of the word drought. The definition of drought has been widely discussed in literature. The discussions cover quantitative aspects, such as different

drought indicators (Satoh et al., 2021), specific drought events such as flash droughts (Schwartz et al., 2023), and a more generalized concept of drought as driven by and as threat to societal systems (Mishra and Singh, 2010; van Loon et al., 2016b). In line with these discussions, our results identify flash droughts, the Meteorological Drought Index, and the Palmer Drought Index as distinct, highly specialized topics within the broader drought research literature (see e.g. highly specialized topics in

475 Figure 2). At a more general level, drought is perceived as systemic, encompassing ecosystem, societal, and economic dimensions. At this level, case studies are particularly useful for quantifying connection strengths and impacts within specific environments (van Loon et al., 2019; van Loon et al., 2024). In genetic and plant physiological research, drought is defined as a system state that hampers plant growth (Gaudin et al., 2013; Moran et al., 2017). In plant genetics, highly specialized topics focus on methods to foster drought tolerance and drought resistance of plants through e.g. enhancing water use efficiency.

480 In agreement with literature, this analysis' results and the topological maps of drought research indicate, that there is not a unique understanding of drought. Rather, the different understandings, scale and concepts are interconnected at both general and specific levels. The results build on the strength of LDA as a method, to calculate connection strengths based on co-occurrence and frequency of multiple keywords and topics rather than focussing on specific terms and meanings. Hence, this 485 method results in maps of connection strengths between different systems, foci and perspectives (Figure 5 and Figure 6).

4.2 Forecasting Methods

490 Forecasting has emerged as a major and increasingly relevant topic in drought research. This growing importance is driven by several factors, including the substantial data requirements, the need for data integration platforms, environmental monitoring systems, and the application of artificial intelligence to generate indices. The identified emerging trends in the highly specialized Tier 3 topics and these factors contribute significantly to the rising prominence of drought forecasting (Wardlow et al., 2017; Pasteris et al., 2005). Additionally, recent occurrences of rapidly developing and large-scale drought events, such as in the La Plata Basin in South America and West Africa (Geirinhas et al., 2023). Highlight the need for enhanced mechanistic understanding and forecasting capabilities. Improved forecasting will improve the readiness to manage more frequent drought 495 conditions and support food security for a growing global population (Krishnamurthy R et al., 2022).

500 Despite the and Future Directions increasing application of machine learning approaches in drought forecasting (Al Mamun et al., 2024; Prodhan et al., 2022), our analysis did not identify machine learning and artificial intelligence as distinct topics. Similarly, early warning systems (Funk et al., 2019) and compound events (Ridder et al., 2022; Yin et al., 2023; Lesk et al., 2022) were not identified as distinct topics although urgency for progress in these topics is perceived (FAO-WFP, 2020). There are two possible explanations for this. First, these topics may not have emerged as distinct areas within the drought research domain and could be distributed across broader research themes. Second, the volume of research on these topics may be

insufficient to form distinct clusters. To make a meaningful impact on drought research, these emerging topics need to gain further momentum through increased publication numbers, research focus and funding mechanisms.

505

4.3 Bridging the Arch of Drought Research

Given the challenges in food and water security, it is now the time to bridge the gap between forecasting drought impacts e.g. under climate change and the consideration of genetic advances in drought tolerance for agricultural production. However, it is particularly challenging to bridge this gap given the distance in the arch of drought research and current similarity between

510 plant genetics and forecasting (Figure 2). Some projects already address this challenge by aiming to include genetic variability of plants in crop models or use crop growth models for identification of climate adapted varieties (Parent and Tardieu, 2014; Chenu et al., 2017). Hence, crop yield forecasts under climate change scenarios must give stronger consideration to genetic advances and plant molecular processes than currently is explored (Stella et al., 2023). Nevertheless, increasing drought crop's drought resilience and forecasting will not suffice as sole mechanisms. Other mitigation strategies at political and ecosystem

515 level can provide equally important and case specific solutions. Knowledge reviews are one tool and required to bridge interdisciplinarity which they already do as illustrated by reviews leading the overall interdisciplinarity score (Figure 6).

4

← Formatiert: Standard

4.14.4 Implications for research, policy and institutions

These findings have significant implications for scientific community, policymakers and institutions addressing drought issues.

520 The current topical research emphasis lies on drought forecasting methods and plant genetics (Figure 4). Both topics guard food security and imply food security as human priority for funding and research interest. Plant genetics provides methods to identify genes and produce variants with higher drought tolerance by altering a variety of physiologic processes (Figure 2). Forecasting explores methods to forecast drought with regard to risk monitoring often related to agricultural impacts and drought indicators; and for specific events (Figure 2). In contrast, topics that address drought impact on socio-ecosystem 525 compartments such as ecology and groundwaterwater resource management held greater importance in the past compared to their current relevance. Policy and funding agencies must decide based on their priorities whether this is a desirable trend or not, and align funding strategies accordingly.

← Formatiert: Schriftart: Kursiv

530 It is now the time to bridge the gap between forecasting drought impacts under climate change and the consideration of genetic advances in crop traits albeit it is particularly challenging, considering the arch of drought research and current similarity between these topics. Some projects already address this challenge by aiming to include genetic variability of plants in crop models or use crop growth models for identification of climate adapted varieties (Parent and Tardieu, 2014; Chenu et al., 2017). Given our results, we urge that crop yield forecasts under climate change scenarios must give stronger consideration to genetic advances and plant molecular processes than currently is explored (Stella et al., 2023). Growing computational

535 resources will provide sufficient technical hardware required. In addition, knowledge reviews as are required to bridge interdisciplinarity which they already do (Figure 6).

Surprisingly, several more recently advocated topics of interest were not fully perceived as emerging topics by our data-driven analysis. Although we identified for example remote sensing and drought indices as emerging topics, machine learning (AI 540 Mamun et al., 2024; Prodhan et al., 2022), compound events (Yin et al., 2023; Lesk et al., 2022) and early warning systems (Funk et al., 2019; FAO-WFP early warning analysis of acute food insecurity hotspots, 2020) were not amongst the emerging topics. Here, topics that should make a meaningful contribution to drought research must gain more momentum and more substance through publication numbers, research focus and funding mechanisms.

545 **4.5 Finally, we inform the development of systemic drought resilience frameworks by identifying the breadth of and quantifying connection strength between topics in drought research. The trend of increasing interdisciplinarity since 2007 must be consolidated and embraced by building drought resilience frameworks that are more systemic in character (Hagenlocher et al., 2023). Central components of drought research such as groundwater, 550 a resource for drinking water supply, cooling and irrigation (Jasechko et al., 2024), and ecosystems, a critical component of Limitation of Latent Dirichlet Allocation**

The data for this research was limited to abstracts, titles, and keywords. While this approach allowed for a large volume of articles to be analyzed over an extended temporal period, it comes with certain limitations. The primary advantage is that abstracts, titles, and keywords are well standardized and harmonized, enabling the inclusion of a vast number of articles. However, a key disadvantage is the uncertainty regarding how accurately these abstracts and keywords reflect the full content 555 and findings of the articles. The results are heavily dependent on the effectiveness of the peer-review process, underscoring the critical role of abstracts in research communication.

A more in-depth study, potentially utilizing more advanced models or normalization procedures, would require additional computational resources (e.g. compare (Callaghan et al., 2020; Ogunleye et al., 2023). For instance, normalizing word 560 frequency could help account for differences in document length. It's important to note that a full-text analysis might reveal that specialized research is more interdisciplinary than it appears from abstract-only analysis. Additionally, the use of semantic analysis could extract further insights and generate more detailed information (Geeganage et al., 2024; Niu et al., 2022).

5 Conclusions and Future Directions

565 This study offers a comprehensive data-driven topology of drought research, providing valuable insights for decision-makers, researchers, and institutions. By mapping the current topical priorities, geographical distribution, emerging trends, and interconnections between research areas, we contribute to the development of systemic drought resilience frameworks. These

frameworks ideally embrace the increasing interdisciplinarity observed since 2007, ensuring a holistic approach to drought resilience (Hagenlocher et al., 2023). Key topics to consider in this context include *climate change impacts, reviews, and remote sensing* which exhibited highest overall interdisciplinarity – and are potentially critical to the effectiveness of systemic drought resilience frameworks (Hagenlocher et al., 2019). Additionally, central components of drought research, such as water resource management – essential for societal applications like drinking water supply, cooling, and irrigation—must be integral to these frameworks (Jasechko et al., 2024).

570 While this analysis highlights current trends, it also identifies areas that are potentially overlooked in drought research. Future research directions should also focus on underrepresented areas, such as the integration of drought impacts on less-studied ecosystems, which are critical to the Earth's life support system (IPCC, 2021) must be included in drought resilience frameworks as well as climate change impacts (Hagenlocher et al., 2019), the topic with highest interdisciplinarity amongst topics of comparable size. Furthermore, the socio-political implications of water scarcity and the development of more 575 localized and culturally sensitive drought resilience strategies deserve greater attention. Notably, the study did not identify machine learning approaches, studies of compound events, and early warning systems as distinct topics, despite their recognized importance in the field. Addressing these gaps will ensure that future drought research not only follows trends but also explores crucial areas that are currently underrepresented, leading to more comprehensive and effective strategies for mitigating drought impacts.

580 585 The trends, geographic patterns, and connection strengths between topics revealed in this study serve as a tool to guide the development of future drought resilience frameworks. While much of the drought research falls into highly specialized areas, our results highlight where topical connections between these topics are strong and where they are weaker. Although this study is grounded in natural language processing of a large scientific corpus, it does not replace a qualitative 590 assessments of scale and event-specific impacts. Instead, it offers a broad overview that complements more specialized research by revealing the overarching connections and trends within drought research. Decision makers, policy institutes and researchers working on response strategies to address drought issues must consider potentially do well by considering the full breadth of outlined topics.

56 Appendix

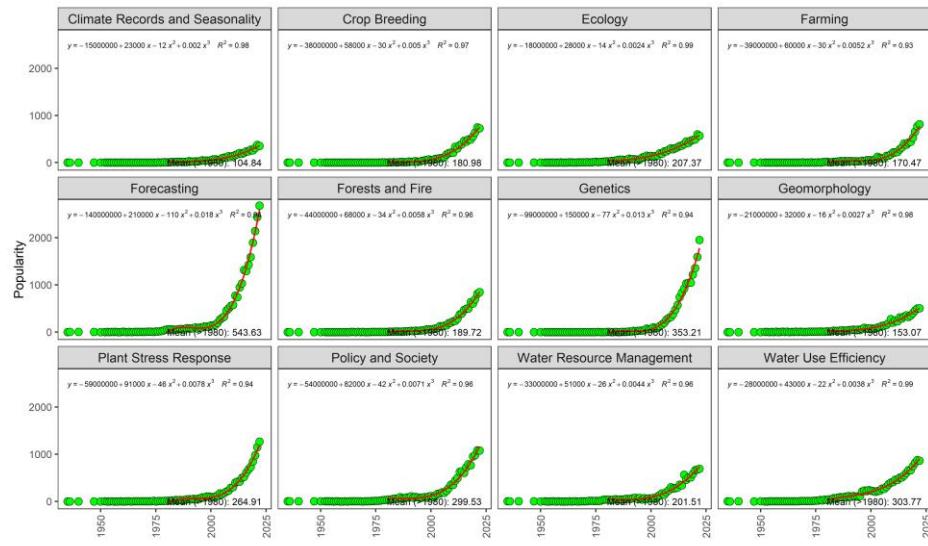

Figure A: Data and trends of total annual publications. Data and polynomial trends of annual publications by major topics per document. Popularity is the number of publication on the particular topic with the polynomial fitted function to indicate the trend since 1980 to 2022 and the mean for this period is given.

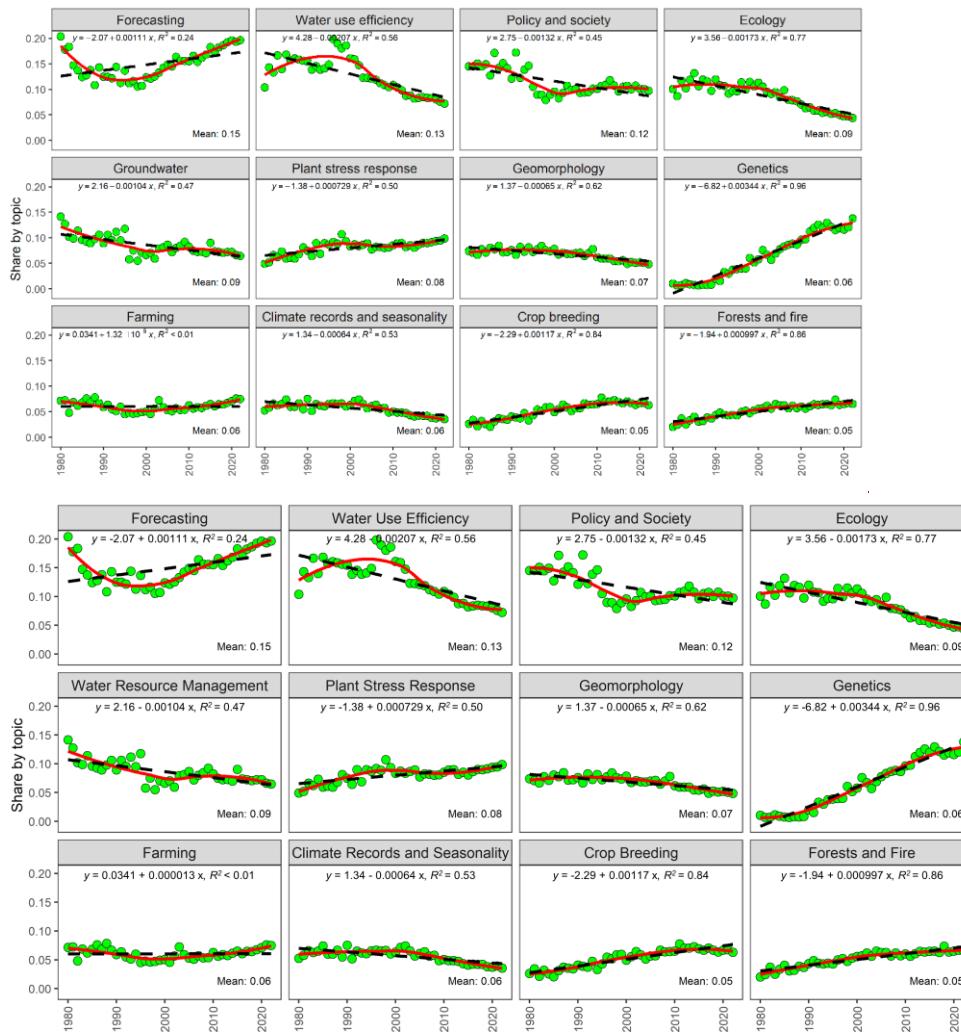

Figure B: Annual share of topics to drought research. Annual shares of research topics ranked by mean annual share. The formula for linear regression provides the trend over the last four decades (black dashed line). Genetics has the highest positive trend with

highest Pearson correlation coefficient. Total publication growth is exponential while annual share refers to the single year, which leads to forecasting and genetics as the topics with highest overall share.
