20 **Abstract.** Gaseous carbonyl compounds serve as crucial precursors and intermediates
21 in atmospheric photochemical reactions, significantly contributing to ambient ozone
22 formation. To determine whether the impact of carbonyl compounds on regional ozone
23 pollution is driven by their abundance or by specific secondary chemical processes,
24 simultaneous field observations and observation-based modelling of ambient carbonyls
25 were conducted at nine sites within the Chengdu Plain Urban Agglomeration (CPUA),
26 China during August 4-18, 2019, when three episodes of regional heavy ozone pollution
27 occurred across eight cities within CPUA. Throughout the study, the total mixing ratios
28 of 15 carbonyls ranged from 10.7_{±4.2} to 35.2_{±13.4} ppbv. The spatial distribution reveal
29 that regions with higher concentrations of carbonyl compounds, such as around
30 Chengdu, are also areas with more severe ozone pollution. Both the abundance and the

删除了: To investigate the impact of gaseous carbonyls on regional ozone pollution,

删除了: 18

删除了: ,

36 chemical reactivity of carbonyl compounds, especially formaldehyde and acetaldehyde,
37 play crucial roles in ozone formation in the CPUA. On ozone pollution days, carbonyl
38 concentrations significantly increased by 22.8% to 66.2%.While the abundance of
39 carbonyls is an important factor, their significant role in heavy ozone pollution within
40 the CPUA is primarily driven by secondary chemical processes, particularly those
41 involving alkenes and BVOCs. Sites with higher average ozone concentrations during
42 observations were mainly in the VOCs-limited regime, while others were in the
43 transitional regime. Additionally, the mutual transport of carbonyl compounds between
44 cities in the CPUA suggests that regional collaboration is essential to address ozone
45 pollution effectively. These findings offer valuable insights for developing effective
46 strategies to control regional ozone pollution.

50 1. Introduction

51 Atmospheric carbonyl compounds play a pivotal role in tropospheric chemistry,
52 acting as crucial precursors to both ozone (O₃) and secondary organic aerosols (SOA),
53 a fact recognized for decades (Altshuller, 1993; Grosjean and Seinfeld, 1989). Their
54 importance has been confirmed by numerous studies over the years(Guo et al., 2004;
55 Hallquist et al., 2009; Wang et al., 2020; Ye et al., 2021; Coggon et al., 2019),
56 highlighting their significant contribution to atmospheric photochemistry and air
57 pollution. Over the past two decades, severe air pollution in China has driven substantial
58 research efforts to understand the contributions of carbonyl compounds to these
59 environmental challenges. Studies have shown that photolysis of carbonyl compounds
60 is a major source of RO_x radicals (Grosjean and Seinfeld, 1989; Zhang et al., 2016).
61 These compounds can be photolyzed and react with OH radicals to form a large number
62 of HO₂ and RO₂ radicals, which increase the atmospheric oxidation capacity and
63 participate in the NO_x photochemical cycle, leading to ozone formation. (Zhang et al.,

删除了: in which formaldehyde (48.1%), acetone (19.9%), and acetaldehyde (17.5%) were most abundant within the CPUA. Ambient levels of carbonyls and ozone showed some positive correlations in space (especially pronounced around Chengdu in both northern and southern directions) and in diurnal variations with higher concentrations of carbonyls during ozone pollution episodes. Photochemical reactivity analysis emphasized the significant contributions of carbonyls, especially formaldehyde and acetaldehyde, to ozone formation.

删除了: The ozone formation sensitivity for sites experiencing severe ozone pollution were classified as VOCs-limited regime, while others were categorized as transitional regime.

删除了: Local primary emissions, mutual air transportation among cities within the CPUA and photochemical secondary processes were recognized to contribute significantly to the production or the contamination of carbonyls in ambient air, with alkenes and alkanes being important secondary precursors of carbonyls. **This study highlights the pivotal role of carbonyls in heavy ozone pollution within the CPUA, China, providing valuable scientific insights to guide the development of effective countermeasures for regional ozone pollution control in the future.**

108 2016; Meng et al., 2017). Additionally, dialdehydes such as glyoxal and methylglyoxal
 109 undergo heterogeneous reactions with aqueous particulate matter, rapidly forming SOA
 110 (Lou et al., 2010; Xue et al., 2016; Yuan et al., 2012). Ambient carbonyl compounds
 111 not only affect the environment but also pose direct health risks to humans. They can
 112 harm ecosystems through deposition and adsorption processes (Yang et al., 2018). They
 113 also pose direct health risks to humans, including sensitization, carcinogenesis, and
 114 mutagenicity (Fuchs et al., 2017).

115 Recent research has increasingly focused on understanding the spatial and
 116 temporal variability of carbonyl compounds in highly polluted regions, particularly in
 117 China, where rapid industrialization has led to severe air quality challenges. Xue et al.
 118 (2013) and Duan et al. (2012) reported typical ambient concentrations of carbonyl
 119 compounds ranging from a few $\mu\text{g}\cdot\text{m}^{-3}$ to tens of $\mu\text{g}\cdot\text{m}^{-3}$ in urban areas, depending on
 120 the specific compounds and regions studied. For example, formaldehyde concentrations
 121 in highly polluted areas can exceed $10\ \mu\text{g}\cdot\text{m}^{-3}$. Shen et al. (2013) and Fu et al. (2008)
 122 observed significant diurnal variation, with higher concentrations of carbonyl
 123 compounds during the daytime, particularly in the afternoon, driven by photochemical
 124 production. Concentrations can increase by as much as 50-100% during peak sunlight
 125 hours compared to nighttime levels. Pang and Mu (2006) and Rao et al. (2016)
 126 identified key sources of carbonyl compounds, including vehicular emissions, industrial
 127 activities, and secondary formation from VOC oxidation in the atmosphere. In urban
 128 environments, vehicular emissions are often a dominant primary source, while
 129 secondary formation contributes significantly during daytime due to photochemical
 130 processes. The results highlight severe and spatiotemporal variations of carbonyl
 131 pollution in China. High levels are found mainly in the North China Plain(NCP), the
 132 Yangtze River Delta(YRD), and the Pearl River Delta(PRD)(Duan et al., 2008; Shao et
 133 al., 2009; Tan et al., 2018; Wang et al., 2018; Xue et al., 2014, 2013; Yang et al., 2017).
 134 Urban areas generally exhibit higher carbonyl levels than suburban and rural areas due
 135 to human activities(Xue et al., 2013). Despite the progress made, significant gaps

243 remain in understanding the spatiotemporal distribution and source apportionment of
244 carbonyl compounds, particularly in urban agglomerations. Existing research has
245 primarily focused on urban areas in rapidly developing regions like the NCP, YRD, and
246 PRD. Moreover, studies have often emphasized the overall role of VOCs in ozone
247 pollution, with less attention given to specific carbonyl compounds and their individual
248 contributions to atmospheric oxidation capacity and ozone formation (Meng et al.,
249 2017).

设置了格式: 非突出显示

250 Monitoring carbonyl compounds in the atmosphere is challenging due to their
251 typically low concentrations (ppt-ppb levels), necessitating highly sensitive analytical
252 methods. The diversity of carbonyl compounds, including multiple isomers, requires
253 highly selective analytical techniques for differentiation. Current measurement
254 technologies limit our understanding of the spatiotemporal distribution of carbonyl
255 compounds, affecting the accurate assessment of their environmental behavior, sources,
256 and transport (Xue et al., 2013; Sahu and Saxena, 2015). While numerous studies have
257 explored the role of carbonyl compounds in ozone production, many focus on general
258 mechanisms rather than specific compounds or regional variations (Atkinson and Arey,
259 2003; Monks et al., 2015).

删除了:

设置了格式: 非突出显示

260 Atmospheric carbonyl compounds originate from both primary and secondary
261 sources (Pang and Mu, 2006; Rao et al., 2016). Primary sources include the incomplete
262 combustion of fossil fuels and biomass, industrial emissions, emissions from the
263 catering industry, and releases from plants. Secondary sources arise from the
264 atmospheric photochemical oxidation of VOCs (Xue et al., 2013), particularly
265 alkenes, aromatics, and isoprene, which typically dominate the secondary formation of
266 carbonyls. However, distinguishing between primary and secondary contributions
267 remains challenging. Existing source apportionment methods, such as characteristic
268 species ratios and multiple linear regression, often lack the resolution to differentiate
269 these sources accurately, especially for non-vehicular emissions and secondary
270 formation. The limitations of these methods underscore the need for more advanced

设置了格式: 突出显示

设置了格式: 非突出显示

272 approaches to better quantify the secondary formation mechanisms of carbonyl
273 compounds and their regional impact on ozone formation. Despite significant
274 advancements in studying atmospheric carbonyls, key gaps remain in understanding
275 their precise spatiotemporal distribution and source apportionment. Specifically, there
276 is a need for studies that examine how carbonyls vary across different environments—
277 urban, suburban, and rural—and during varying pollution events. Without such targeted
278 analysis, our understanding of the behavior of carbonyl compounds and their
279 contribution to ozone pollution remains incomplete, particularly in regions
280 experiencing severe pollution.

281 This study focuses on atmospheric carbonyl compounds and their roles in
282 photochemical pollution within the Chengdu Plain Urban Agglomeration (CPUA) of
283 China. The CPUA includes eight cities: Chengdu, Mianyang, Deyang, Leshan, Meishan,
284 Yaan, Suining, and Ziyang. This region has a developed economy and a high degree of
285 internationalization. The CPUA is located on the western edge of the Sichuan Basin,
286 surrounded by mountain ranges, which easily block airflow. The unique climatic
287 environment of the CPUA features low wind speeds year-round, high frequency of
288 static winds, short hours of sunshine, frequent winter inversions, and a pronounced heat
289 island effect in summer. These climatic characteristics significantly impact the
290 variations in air pollutant concentrations, making the region prone to ozone pollution
291 in summer and haze pollution in winter (Li et al., 2013; Hu et al., 2017; Zhang et al.,
292 2010). Although previous studies have shown that ozone formation in urban Chengdu
293 is primarily VOCs-limited (Tan et al., 2018), with aromatic hydrocarbons and alkenes
294 contributing significantly to ozone generation in summer (Xu et al., 2020), these studies
295 mainly focus on single cities and overall VOCs. There is still limited understanding of
296 whether the significant roles of carbonyl compounds in ozone formation are primarily
297 due to their abundance or whether specific chemical reactions involving carbonyls drive
298 this process. This study aims to address these gaps by investigating the spatial
299 distribution, sources, and specific chemical pathways of carbonyl compounds across

删除了: At present, the analysis methods for the sources of carbonyl compounds mainly include characteristic species ratio, source tracer proportion, multiple linear regression, parameterization method based on photochemical age, and acceptor model. There are usually differences in the source classifications obtained in different studies, due to the different methods of source analysis employed. But generally, for formaldehyde and acetaldehyde with high reactivities, their sources vary significantly across studies; and for acetone with low reactivity, the sources are relatively similar. However, current knowledge of the sources of carbonyl compounds is far from providing scientific support for air quality improvements. Meanwhile, most of the research on their health effects has focused on indoor carbonyl compounds (Yuan et al., 2013). Research on the health effects of atmospheric carbonyl compounds should be strengthened.

删除了: The Chengdu Plain Urban Agglomeration (CPUA) of China is centered

360 the entire CPUA and assessing their contributions to regional ozone pollution and inter-
361 city air transport mechanisms.

362 To address these research gaps, this study involves an intensive field observation
363 experiment conducted by the Sichuan Academy of Environmental Sciences, Peking
364 University, Sichuan University and Chinese Academy of Environmental Sciences.
365 Atmospheric carbonyl compounds were observed at nine sites in eight cities within the
366 CPUA for 15 days during a period of heavy ozone pollution in August 2019. Samples
367 were analyzed using 2,4-dinitrophenylhydrazine solid phase adsorption/high
368 performance liquid chromatography (HPLC). The study aims to characterize the
369 atmospheric carbonyl compounds in the CPUA, assess their influence on
370 photochemical pollution, identify key carbonyl compounds that may play crucial roles
371 in heavy ozone pollution in the CPUA, and evaluate the contribution of primary
372 emissions, air pollution transport, and secondary generation to key carbonyl compounds
373 through a combination of multivariate linear regression modeling and Observation-
374 Based Modeling (OBM). This research aims to provide technical support for controlling
375 carbonyl compounds pollution in the CPUA and to reduce their contributions to ozone
376 pollution.

377 2. Materials and methods

378 2.1 Observation Sites Profile

379 In this study, a total of 9 off-line sampling sites for atmospheric carbonyl
380 compounds were set up in 8 cities in the CPUA from August 4th to 18th, 2019(table S1).
381 Considering that this study focused on the pollution characterization of carbonyl
382 compounds in urban areas, one urban site was selected in each city. In addition, in order
383 to compare and study the pollution characteristics of carbonyl compounds in the
384 suburbs, a suburban site was set up in Xinjia County, Chengdu. For the selection of
385 urban sites in each city, priority is given to those choices of set-up in the vicinity of the
386 state-controlled site, and the perimeter of the sites should be open, unobstructed and no

删除了: However, the previous studies on the causes and sources of ozone pollution in the CPUA mainly focused on the contribution and sources of ozone formation by VOCs other than carbonyl compounds in Chengdu urban area. And there is a lack of research on the overall atmospheric levels of atmospheric carbonyl compounds in the CPUA and their effect on ozone formation during the same period.

430 obvious pollution sources, with convenient transportation and power supply. The
431 distribution of specific sites is shown in Fig. 1.

432 Ozone concentrations were measured using the UV absorption method with a
433 Thermo O₃ analyzer (Model 49i), with data sourced from national control stations near
434 each sampling site. Nitrogen dioxide (NO₂) was measured by chemiluminescence
435 following chemical conversion to nitric oxide (NO) using a molybdenum catalyst;
436 however, this method is known to have interferences from other NO_x species. Carbon
437 monoxide (CO) was measured via infrared absorption with a Thermo instrument
438 (Model 20). All Thermo instruments were carefully maintained and calibrated daily at
439 01:00 to ensure measurement accuracy. Measurements for ozone, NO₂, and CO were
440 collected with a time resolution of one hour. Simultaneously, meteorological
441 parameters—temperature, relative humidity (RH), wind speed, and direction—were
442 recorded at each observation site using an automatic weather station (PC-4, JZYG,
443 China), also at a one-hour resolution.

451 2019), with ozone data obtained from national control stations near each sampling site. Black dots
452 represent the locations of the sampling sites, labeled as follows: MY (Mianyang), DY (Deyang),
453 CDHKY (Chengdu Environmental Science Research Institute), XJ (Xinjin), SN (Suining), ZY
454 (Ziyang), MS (Meishan), YA (Ya'an), and LS (Leshan). The color bar in the top left corner
455 corresponds to interpolated ozone concentrations, with each color representing a concentration
456 gradient.

457 2.2 Samples Collection

458 The sampling of atmospheric carbonyl compounds mainly referred to the TO-11A
459 standard of the United States Environmental Protection Agency (US EPA) and the
460 Chinese environmental protection standard HJ 683-2014 High Performance Liquid
461 Chromatography Method for the Determination of Atmospheric Carbonyl Compounds,
462 and the sampling was carried out by using silica gel sampling tubes (IC-DN3501 from
463 Tianjin Bonna-Agela) coated with DNPH (2,4-dinitrophenylhydrazine). In this study,
464 an automatic sampler for carbonyl compounds (Zhang et al., 2019) was used to
465 continuously collect atmospheric carbonyl compounds. From August 4th to 18th, 2019,
466 air samples were collected every 2 hours with a sampling flow rate of $0.8 \text{ L} \cdot \text{min}^{-1}$. In
467 addition, in order to prevent the impact of ozone and rainwater in the atmospheric air
468 on sample collection, a potassium iodide ozone removal column (KI 140 from Tianjin
469 Bonna-Agela) was installed and a water removal agent made by ourselves (Bao et al.,
470 2022; Wang et al., 2020) was added at the front end of the sample tube. Two blank
471 samples were collected before and after the sampling, and blank samples were also
472 collected for different batches of sampling tubes. The samples were frozen at -18°C and
473 analyzed within one month.

474 Atmospheric VOCs were sampled using SUMMA tanks, stainless steel tanks with
475 electropolished and silanized inner walls, manufactured by Entech in the United States,
476 with a sampling volume of 3.2 liters. The sampling was controlled by a constant current
477 integral sampler to sampling for an average of 1 hour. From August 4th to 18th, 2019,
478 two VOCs samples were collected each day at each site, at 8:00-9:00 and 14:00-15:00
479 (no samples were taken under special weather conditions, such as rain). On August 11th,
480 12th and 16th, six samples were collected per day to capture diurnal variations under

489 ozone pollution events, at the following times: 8:00-9:00, 10:00-11:00, 12:00-13:00,
490 14:00-15:00, 16:00-17:00, and 18:00-19:00.

删除了: (8:00-9:00, 10:00-11:00, 12:00-13:00, 14:00-15:00, 16:00-17:00, and 18:00-19:00).

491 2.3 Samples Analysis

492 The carbonyl compounds samples were qualitatively and quantitatively analyzed
493 by using High Performance Liquid Chromatography (HPLC) (LC-20AD, Shimadzu,
494 Japan) and an ultraviolet detector (SPD-20A, Shimadzu, Japan), mainly based on the
495 US EPA TO-11A standard and the Chinese HJ 683-2014 standard. The DNPH sampling
496 column after sampling was slowly eluted into a volumetric flask using acetonitrile
497 (chromatographically pure, Thermo Fisher Scientific China) to 5.0 mL. Then 1.5 mL of
498 the sample was transferred into an HPLC sample bottle, and sealed and stored in a
499 refrigerator at <4 °C to complete the pre-treatment. Prior to sample analysis, a standard
500 solution of the concentration gradient was prepared using TO-11A standard solution
501 (Supelco, USA) and used as the external standard. The correlation coefficient (R^2) of
502 the standard curve was greater than 0.995. The detection limit of the device was
503 0.56~5.57 ng·mL⁻¹, and the quantification limit was 1.87~18.56 ng·mL⁻¹ (Table S2).
504 Then 20 μL of the pretreated sample was extracted through the autosampler and injected
505 into the HPLC/UV system, detected by a UV detector with a wavelength of 360 nm,
506 qualified by retention time value, quantified by peak area value, and the qualitative and
507 quantitative analysis data of carbonyl compounds were obtained after conversion. The
508 HPLC conditions referred to Chinese environmental protection standard HJ 683-2014:
509 binary gradient washing was performed using acetonitrile and water, 60% acetonitrile
510 was held for 20 mins, acetonitrile was increased linearly from 60% to 100% within 20-
511 30 mins, and acetonitrile was reduced to 60% again within 30-32 mins and held for 8
512 mins; the column oven was kept at 40 °C. It should be noted that while the sampling
513 and analysis method was effective for most carbonyl compounds, ketones, including
514 methyl vinyl ketone (MVK), were not well sampled during the field observations. As a
515 result, data for MVK and other ketones were missing. During the observation period,
516 DNPH cartridges and HPLC analysis technique were used to detect a total of 15

524 carbonyl compounds (Table S2).

525 The atmospheric VOCs were analyzed using the TO-14 and TO-15 methods,
526 which are recommended by the US EPA. These methods involve frozen
527 preconcentration coupled with gas chromatography and mass spectrometry (GC-MS).
528 TO-15 is a method for detecting and quantifying a wide range of VOCs from air samples.
529 The VOCs were pre-concentrated by the Entech7100 system at a low temperature, then
530 quantified by an Agilent GC-MS. During the sample analysis, four internal standard
531 gases (bromochloromethane, 1,4-difluorobenzene, chlorobenzene-d5, and 4-
532 bromofluorobenzene) were used. A multi-point calibration curve was created using a
533 standard gas containing 118 VOCs, including PAMS compounds, TO-15 target analytes,
534 and carbonyl compounds. PAMS (Photochemical Assessment Monitoring Stations)
535 compounds are a subset of hydrocarbons known to contribute to ozone formation, such
536 as ethane, ethylene, propane, and others.

537 2.4 Data Analysis

538 2.4.1 Ozone pollution assessment criteria

539 According to the Technical Regulation on Ambient Air Quality Index (on trial),
540 National Environmental Protection Standard of the People's Republic of China HJ
541 633—2012, days with an ozone pollution index (IAQI) of 100 or higher during the
542 observation period were designated as pollution days, while days with an IAQI below
543 100 were considered clean days. This study compared the pollution characteristics of
544 carbonyl compounds between pollution days and clean days. Additionally, the
545 concentrations of formaldehyde, acetaldehyde, and acetone observed during the
546 summer of 2009-2013 in economically developed and industrialized areas such as
547 Beijing, Shanghai, and Guangzhou in China, as well as locations in South America
548 (Brazil), Asia (Thailand), Europe (France), and North America (United States), were
549 selected and compared.

550 2.4.2 Ozone formation sensitivity

The concentrated samples were separated by gas chromatography and then entered mass spectrometry for detection. A hydrogen flame ionization detector (FID) was used to detect 5 substances: ethane, ethylene, acetylene, propane, and propylene. During the sample analysis, four internal standard gases bromochloromethane, 1,4-difluorobenzene, chlorobenzene-d5 and 4-bromofluorobenzene were used. With a standard gas containing 118 substances such as PAMS, TO-15 and carbonyl compounds, a multi-point calibration standard working curve was established using 6 concentration gradients....

删除了: Ambient levels comparison

删除了: Ozone formation sensitivity inferring

572 Previous studies have shown that the formaldehyde to NO₂ ratio (FNR) can be
573 used to determine the sensitivity of O₃-NO_x-VOCs (Schroeder et al., 2017; Tonnesen
574 and Dennis, 2000; Vermeuel et al., 2019). Most studies used satellite remote sensing-
575 based FNR, but the FNR column concentration ratios inverted by satellite remote
576 sensing mainly represented the average photochemical of the troposphere, and the
577 concentration distributions of HCHO and NO₂ in the vertical direction were
578 inconsistent (Hong et al., 2022; Schroeder et al., 2017). So, there is a large uncertainty
579 to develop ground-level ozone pollution prevention and control measures. In this study,
580 sensitivity analysis of ground-level ozone formation was carried out based on the ratio
581 of ground-level HCHO to NO₂ during the observation period at the 9 sites of 8 cities in
582 the CPUA. FNR < 0.55±0.16 and FNR > 1.0±0.3 were defined to VOCs-limited and
583 NO_x-limited, respectively, and FNR ratio ranged from 0.55±0.16 to 1.0±0.3 defined to
584 NO_x and VOCs co-limited (Liu et al., 2021; Zhang et al., 2022).

585 2.4.3 Exploration of Secondary Formation Mechanisms

586 (1) Atmospheric chemical reactivity

587 In this study, the contribution of atmospheric chemical reactivity of carbonyl
588 compounds to ozone formation was evaluated using the OH free radical consumption
589 rate (L_{OH}) and ozone formation potential (OFP):

$$590 L_{OH} = [\text{OVOC}]_i \times k_i(\text{OH}) \quad (1)$$

591 Where, [OVOC]_i was the observed concentration of the ith (i=1 to n) carbonyl
592 compound, in molecule·cm⁻³; k_i(OH) was the rate constants of the ith carbonyl
593 compound reacting with OH radicals, in cm³·(molecule·s)⁻¹. The unit of L_{OH} is s⁻¹,
594 representing the rate of OH radical consumption. The selected k_i(OH) values were from
595 literature (Atkinson and Arey, 2003).

$$596 \text{OFP} = \text{MIR}_i \times [\text{OVOC}]_i \quad (2)$$

597 Where, MIR was the maximum incremental reactivity of the ith carbonyl
598 compound, in g O₃·(g VOC)⁻¹ (grams of ozone formed per gram of volatile organic

610 (2) Observation-based model (OBM)

611 The Observation-Based Model (OBM) is a box model that uses actual
612 observational data to evaluate the sensitivity of secondary pollutant formation
613 mechanisms to their precursor emissions. By constraining the model with atmospheric
614 observation data, typical secondary pollutants and parameters such as NO_x, SO₂, CO,
615 VOCs, temperature, humidity, pressure, and JNO₂ are input into the model as hourly
616 observational data to calculate the chemical formation and consumption of secondary
617 pollutants and free radicals. In this study, the OBM model used the Master Chemical
618 Mechanism (MCM) (v3.3.1, mcm.leeds.ac.uk), which is a nearly detailed chemical
619 mechanism that describes the chemical processes of 143 VOC species from emission
620 to degradation in the atmosphere, including approximately 6,700 species and 17,000
621 inorganic and organic reactions. In this version of the MCM, a total of 19 carbonyl
622 compounds are included, comprising 9 aldehydes and 10 ketones. Of these, 9 carbonyl
623 compounds were measured in this study, including formaldehyde, acetaldehyde,
624 acetone, propionaldehyde, crotonaldehyde, butyraldehyde, isovaleraldehyde,
625 valeraldehyde, and hexaldehyde. The MCM chemical mechanism can simulate
626 atmospheric photochemical reaction processes under near-real conditions and calculate
627 the concentrations of highly reactive species, quantifying the reaction rates of all
628 species involved. For VOCs, especially carbonyls, that were not directly measured, the
629 MCM uses estimated values derived from emission inventories, literature data, and
630 assumptions based on similar species to provide estimates for their concentrations and
631 reaction rates.

632 Relative Incremental Reactivity (RIR) was first used by Cardelino and Chameides

634 (1995) to simulate the response of ozone to precursor changes through scenario tests
635 using box model calculations. RIR was calculated by assuming that the concentration
636 of a given carbonyl compound precursor decreased by a certain proportion could cause
637 the change of the concentration of the carbonyl compound, so as to further judge the
638 effect of VOCs on the formation of carbonyl compounds. Combining the concentrations
639 and activity levels of 15 carbonyl compounds during the observation period, this study
640 focused on formaldehyde, acetaldehyde, and acetone as the primary research targets.
641 The impacts of various AVOCs (anthropogenic VOCs) including alkanes, alkenes,
642 alkynes, and aromatic hydrocarbons, as well as BVOCs (biogenic VOCs) like isoprene,
643 on the formation of formaldehyde, acetaldehyde, and acetone were assessed using
644 observation-based OBM classification. Specific species of anthropogenic source VOCs
645 (alkanes, alkenes, alkynes, and aromatic hydrocarbons) and biogenic VOCs (isoprene)
646 are detailed in Table S3.

删除了: The relative incremental activity

删除了: (RIR)

647 VOCs observations, conventional gases (NO₂, CO and SO₂) and meteorological
648 parameters (temperature, relative humidity and pressure) were imputed into the model.
649 It was assumed that the pollutants are well mixed. Under the constraints of the measured
650 hourly concentration data of pollutants, the atmospheric chemical process was
651 simulated to obtain the source-effect relationship of the measured pollutants. By
652 assuming the reduction of the source effect, the RIRs of different carbonyl compounds
653 precursors were calculated, and the sensitivities of carbonyl compounds to different
654 pollutants were obtained, and then the secondary formation mechanism of carbonyl
655 compounds was determined. The formula to calculate the RIR is as follows:

$$656 \quad RIR(X) = \left[\frac{\Delta P_Y(X)/P_Y(X)}{\Delta S(X)/S(X)} \right] \quad (3)$$

$$657 \quad P_Y = Y_{\text{net formation}} - Y_{\text{net consumption}} \quad (4)$$

658 Where X was a specific species; P_Y(X) was the net formation rate of species y;
659 S(X) was the total amount of emissions of species X in a certain period, i.e., the source
660 effect of species X. ΔS(X) was the change in total emissions of X caused by the
661 hypothetical change in source effect, ΔP_Y(X) was the change in P_Y(X) after the change

删除了:

删除了:

666 in source effect $S(X)$, and $RIR(X)$ was the relative incremental reactivity of species X.
667 The species Y in this study were formaldehyde, acetaldehyde and acetone, respectively,
668 and pollutant X was reduced by 20%.

669 The absolute RIR of the precursor reflects the sensitivity of carbonyl compounds
670 formation to the precursor. The higher the absolute RIR, the more sensitive the carbonyl
671 compounds formation to the precursor. A positive RIR value indicates that reducing the
672 species can reduce the formation rate of species Y, and a negative RIR value indicates
673 that reducing the species can increase the formation rate of species Y.

674 2.4.4 Sources Analysis

675 (1) Multi-linear regression model

676 There is a good correlation between concentrations of compounds of the same or
677 similar source in the atmosphere. Based on this property, it was assumed that the
678 primary and secondary sources of carbonyl compounds were linearly correlated with
679 the selected tracers, and then a quantitative source model was established by multiple
680 linear statistical regression analysis (Kanjanasiranont et al., 2016a; Li et al., 2010; Ling
681 et al., 2017; Luecken et al., 2012; Lui et al., 2017; Wang et al., 2017). In general, CO is
682 the marker product of typical anthropogenic combustion source emissions, mainly from
683 vehicle exhaust emissions and coal combustion. Ozone, as an indicator of
684 photochemical smog, is a typical secondary formation pollutant. In this study, CO and
685 ozone were selected as the tracers of primary source and secondary source of carbonyl
686 compounds, respectively. The formula is as follows:

$$687 \quad [carbonyl] = \beta_0 + \beta_1[CO] + \beta_2[O_3] \quad (6)$$

688 Where $[carbonyl]$, $[CO]$ and $[O_3]$ represented the observed mixing ratios of
689 carbonyl compounds, CO and ozone, respectively, in ppbv. β_0 , β_1 and β_2 were
690 coefficients obtained by multiple linear regression fitting model, in ppbv/ppbv. β_0
691 represented the background concentration of a given carbonyl compound, β_1
692 represented the emission ratio of the carbonyl compound relative to CO. $\beta_1[CO]$ and

693 $\beta_2[O_3]$ represented the concentrations of carbonyl compound in primary emission and
694 secondary formation, respectively, in ppbv.

695 In addition, the relative contribution of primary emissions, secondary formation
696 and background concentrations of carbonyl compounds can be calculated using the
697 following formula:

$$698 \quad P_{primary} = \frac{\beta_1[CO]_i}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (7)$$

$$699 \quad P_{secondary} = \frac{\beta_2[O_3]_i}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (8)$$

$$700 \quad P_{background} = \frac{\beta_0}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (9)$$

701 Where, $P_{primary}$ represented the contribution of the primary emission of a given
702 carbonyl compound, %; $P_{secondary}$ represented the contribution of the secondary
703 formation of the carbonyl compound species, %; $P_{background}$ represented the contribution
704 of the carbonyl compounds species from sources other than primary emissions and
705 secondary formation, %.

706 (2) Backward trajectory model

707 The effects of long-distance air mass transport on the pollution of carbonyl
708 compounds in the CPUA were studied using MeteoInfo software and TrajStat plug-in
709 (<http://www.meteothink.org/downloads/index.html>). In this model, meteorological
710 data were relevant meteorological data from the global data assimilation system (GDAS)
711 database (<ftp://arlftp.arl.hq.noaa.gov/pub/archives/gdas/>). A trajectory simulation height
712 of 500 m above ground level (AGL) was selected. The duration of backward trajectory
713 was 48 h. The daily start time was 00:00 UTC. The analog frequency was 2 h. The
714 backward trajectory diagram was calculated. Meanwhile, the clustering method in
715 TrajStat software and the Euclidean distance algorithm were used to cluster the airflow
716 trajectory to the CPUA. And then the statistical analysis was carried out in combination
717 with the corresponding pollutant mass concentration characteristics.

718 3. Results and Discussion

722 3.1 Overview of air quality during observation period

723 Due to the influence of cooling and precipitation caused by cold air intrusion, the
724 early observation period (from August 4th to 6th, 2019) in the Chengdu Plain Urban
725 Agglomeration (CPUA) experienced slightly lower temperatures (25.1°C) and higher
726 humidity (87.6%). These conditions were unfavorable for ozone formation. Although
727 ozone itself is not easily removed by rain, precipitation reduces ozone pollution by
728 washing away its precursors, such as nitrogen oxides (NO_x) and polar volatile organic
729 compounds (VOCs), such as aldehydes, ketones, and others, decreasing sunlight
730 exposure, and enhancing atmospheric dispersion. However, as temperatures increased
731 and humidity dropped in the subsequent days, more favorable conditions for ozone
732 formation emerged, leading to heavy and persistent regional ozone pollution in the
733 CPUA. By August 12th, the mean temperature had gradually increased to 29.1°C, while
734 it averaged 27.7°C from August 13th to 14th. During this time, cumulative precipitation
735 reached 975 mm, resulting in temporary alleviation of ozone pollution. Subsequently,
736 temperatures rose again from August 15th to 18th, with the mean temperature persisting
737 above 28.4°C for several days, accompanied by a decrease in humidity to a minimum
738 of 64.8% on August 17th. Overall, during the observation period (from August 4th, 2019,
739 0:00 to August 18th, 2019, 24:00), three episodes of severe ozone pollution occurred,
740 namely EP1 (August 7th to 9th), EP2 (August 10th to 13th), and EP3 (August 15th to 18th),
741 as depicted in Fig. 2.

742 Fig.3 illustrates the temporal and spatial variations of ozone and NO₂
743 concentrations, as well as temperature and humidity at each site during the observation
744 period. After observing the spatial distribution of ozone concentration during EP1, it's
745 evident that the severity of pollution reached heavily polluted levels, with Chengdu
746 recording an MDA8 concentration of 297 μg·m⁻³ on August 7th. This distribution
747 demonstrated a radial decrease from Chengdu to the surrounding areas. However, the
748 subsequent episodes, EP2 and EP3, exhibited even broader ranges of ozone pollution
749 and more pronounced spatial movements. During the early stages of EP2 and EP3 (from

756 August 10th to 11th and from August 14th to 15th, respectively), high ozone
757 concentrations were observed in the Chengdu-Deyang-Mianyang region. In the middle
758 stages (August 12th and from August 16th to 17th, respectively), influenced by northerly
759 airflow, regions with high ozone concentrations expanded to the central (Meishan,
760 Ziyang, and Suining) and southwestern (Leshan and Ya'an) parts of the CPUA. In the
761 later stages (August 13th and August 18th), under the influence of northwesterly airflow,
762 regions with high ozone concentrations (Meishan and Leshan) moved southward again,
763 while ozone pollution in other areas of the CPUA gradually weakened. On August 11th
764 to 12th and August 16th to 17th, ozone concentrations in the eight cities of the CPUA
765 reached light pollution levels or higher, with the heaviest pollution recorded on August
766 12th. Specifically, Deyang, Mianyang, Suining, and Meishan reached moderate
767 pollution levels, while Chengdu reached heavy pollution with a concentration of 324
768 $\mu\text{g}\cdot\text{m}^{-3}$.

776 3.2 Comparative characterization of carbonyl compounds

777 3.2.1 Ambient levels

778 During the observation period, we utilized 2,4-dinitrophenylhydrazine (DNPH)
 779 cartridge and high-performance liquid chromatography (HPLC) analysis technique to
 780 quantify 15 carbonyl compounds. The concentrations and relative proportions of these
 781 compounds are summarized in Table 1. The average total concentration of the 15
 782 carbonyls in the CUA was 17.4 ± 5.3 ppb. Overall, areas with elevated concentrations
 783 of carbonyl compounds were primarily concentrated in and around Chengdu in both
 784 northern and southern directions. MY site, located to the north of Chengdu, exhibited
 785 the highest concentration of carbonyl compounds (35.2 ± 13.4 ppb), while YA site,
 786 situated southwest of Chengdu, showed the lowest concentration (10.7 ± 4.2 ppb).

1237

1238 Fig.S1 illustrates the relationship between ozone concentration and carbonyl
1239 compounds concentration at each site during the observation period. It is evident that
1240 the spatial distribution of carbonyl compound concentrations is similar to that of ozone
1241 concentration. Regions with severe ozone pollution tend to exhibit higher
1242 concentrations of carbonyl compounds. The variation in carbonyl compound
1243 concentrations is primarily attributed to anthropogenic emissions and prevailing
1244 summer wind directions in the CPUA. Chengdu is the most economically developed
1245 city in the CPUA, with notably higher GDP and industrial production values than other
1246 regions. Chengdu's major industries include coal-fired power plants, chemical plants,
1247 metallurgy and building materials plants, and high concentrations of carbonyls were
1248 observed in here. The unique basin climate of the CPUA, characterized by intense
1249 sunlight and stable atmospheric conditions, facilitates the accumulation of pollutants.
1250 Large amount of industrial emissions and strong photochemical reaction contributes to
1251 ozone pollution. Additionally, during the summer, prevailing northerly winds in the
1252 CPUA facilitate the downwind transport of pollutants from upwind sources, leading to
1253 regional pollution. It is noteworthy that the concentration of carbonyl compounds at the
1254 MY site significantly exceeds that at the CDHKY site. Mianyang, with its industrial
1255 roots, consistently maintains its position as the second-highest GDP contributor in
1256 Sichuan Province. The electronics information industry stands as Mianyang's primary
1257 economic driver, constituting approximately half of the city's total output value. Studies
1258 investigating the volatile organic compound (VOC) source profile in Chengdu(Zhou et
1259 al., 2021) reveal that ethanol and carbonyls predominantly characterize electronics
1260 manufacturing emissions.

1261 3.2.2 Compositional characteristics

1262 According to the composition characteristics of 15 carbonyl compounds in the
1263 ambient air of each city during the observation period (Table S4). Formaldehyde was

1266 the most abundant carbonyl, found in these sites followed by acetone and acetaldehyde,
1267 which is widely observed in previous studies. The measured ratios of formaldehyde,
1268 acetone, and acetaldehyde across different sites ranged from 36.4% to 59.4% (average
1269 48.1%), 12.4% to 28.1% (average 19.9%), and 8.2% to 47.3% (average 17.5%),
1270 respectively. In this study, the total measured of formaldehyde, acetaldehyde, and
1271 acetone (FAT) account for over 78% of the total carbonyls concentrations. At the MY
1272 and ZY sites, this proportion even exceeded 90%. It is noteworthy that isobutyraldehyde
1273 (MACR) ranks fourth in the volume concentration of 15 carbonyls measured in the
1274 ambient air surrounding XJ, accounting for 5.3%. MACR, a characteristic product of
1275 isoprene photooxidation from biogenic sources, possibly originates from the abundant
1276 vegetation surrounding XJ. It reflects the period's relatively active photochemical
1277 reactions, with substantial contributions from secondary formation to the measured
1278 carbonyls composition.

1279 The observed levels of FAT in different areas were influenced by various factors
1280 including sampling period, geographic location, meteorological conditions, chemical
1281 removal, and source emissions(Z. Zhang et al., 2016). Despite these influences,
1282 comparisons remain valuable in providing an overview of ambient carbonyl levels in
1283 the CPUA. During the summer of 2010, a national wide survey of ambient
1284 monocarbonyl compounds were conducted simultaneously in nine sites (Ho et al.,
1285 2015)found that the total FAT concentration was highest in Chengdu (14.96 ppb),
1286 followed by Beijing (11.83 ppb), and Wuhan (11.70 ppb). Beijing, as the capital of
1287 China, and Wuhan, being one of the top ten most populous cities in China, played
1288 significant roles in this comparison. In our study, the CDHKY site within CPUA
1289 exhibited the highest FAT concentration, with values of 18.25 ppb, surpassing those
1290 recorded in 2010. Furthermore, the total FAT concentrations observed at the CPUA and
1291 XJ sites, with values of 14.99 ppb and 14.90 ppb respectively in our study, closely
1292 resemble those reported in August 2010 in Chengdu. The consistently high levels of
1293 carbonyl compounds observed in Chengdu, both in 2010 and our current study, indicate

删除了: specie

删除了: concentration

删除了: concentrations

1297 that the city likely experiences higher concentrations of these pollutants compared to
1298 other regions across the country. However, more extensive temporal data would be
1299 beneficial to fully validate this pattern at a national scale. Comparing our findings to
1300 international studies, the FAT concentrations at the CDHKY site were lower than those
1301 reported in Rio De Janeiro, Brazil(da Silva et al., 2016), during July to October 2013
1302 (35.43 ppb), but higher than those in Bangkok, Thailand(Kanjanasiranont et al., 2016b),
1303 Orleans, France(Jiang et al., 2016), and the United States(Murillo et al., 2012), with
1304 values of 9.05 ppb, 6.12 ppb, and 5.76 ppb, respectively.

1305 3.3 Temporal variations of carbonyl compounds

1306 The diurnal variation of the total mixing ratio of ambient carbonyl compounds and
1307 ozone concentration around each site in the CUPA during the observation period is
1308 shown in Fig. 4. According to the observation results, the diurnal trend of ozone
1309 concentration at each site showed a "unimodal" variation characteristic, that was, it
1310 gradually increased from the morning to the peak of one day at noon, and then decreased.
1311 The diurnal variation of the total mixing ratio of carbonyl compounds at each site
1312 generally showed a characteristic of high during the daytime and low at night. The
1313 concentration of carbonyl compounds during the day (6:00-16:00) was 48.8% higher
1314 than that at night (18:00-4:00) at the XJ site. This indicated that the concentration of
1315 carbonyl compounds increased by photochemical production during the daytime.

1316 Additionally, deposition processes, particularly dry deposition at night, likely
1317 contribute to the observed diurnal variation in carbonyl levels. The diurnal variation
1318 characteristics of each site were different. For example, the diurnal variation
1319 characteristics of carbonyl compounds concentration at CDHKY, XJ and SN sites were
1320 consistent with those of ozone. The diurnal variation of carbonyl compounds
1321 concentrations at other sites showed "double peaks", peaking at 10:00-12:00 and 18:00-
1322 20:00, respectively. The concentrations of carbonyl compounds at night were also
1323 higher at MY, DY and LS sites. The diurnal minimum values of the total concentration
1324 of carbonyl compounds and ozone concentration appeared at similar time, usually at

删除了: This suggests that elevated concentrations of carbonyl compounds in Chengdu have been a longstanding issue on a national scale.

1328 4:00 a.m. or 6:00 a.m. The first peak of the total mixing ratio of carbonyl compounds
 1329 occurred earlier than the maximum ozone concentration of the day. The first peak of
 1330 the total mixing ratio of carbonyl compounds mostly occurred between 10:00 and 12:00.
 1331 And the maximum ozone concentration mostly occurs between 14:00 and 16:00. This
 1332 was related to the fact that carbonyl compounds were important precursors of ozone.

1333 In general, the diurnal variation of the total concentration of carbonyl
 1334 compounds on pollution days and clean days was high during the daytime and low at
 1335 night. The total mixing ratio of carbonyl compounds on pollution days was 22.8%-
 1336 66.2% higher than that on clean days. At the same time, the increase of concentration
 1337 of carbonyl compounds during the daytime on pollution days was higher than that on
 1338 clean days. This suggested that the increase in the concentration of carbonyl
 1339 compounds during the daytime contributed to ozone pollution.

1340
 1341 **Figure 4.** Diurnal variations of carbonyl compounds and ozone concentrations at each site in the
 1342 CPUA during the observation period

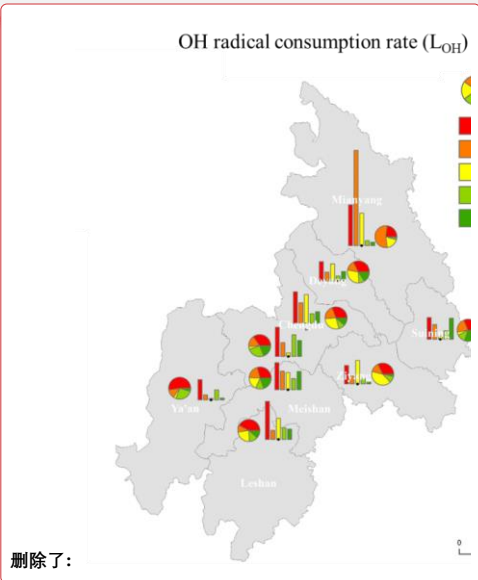

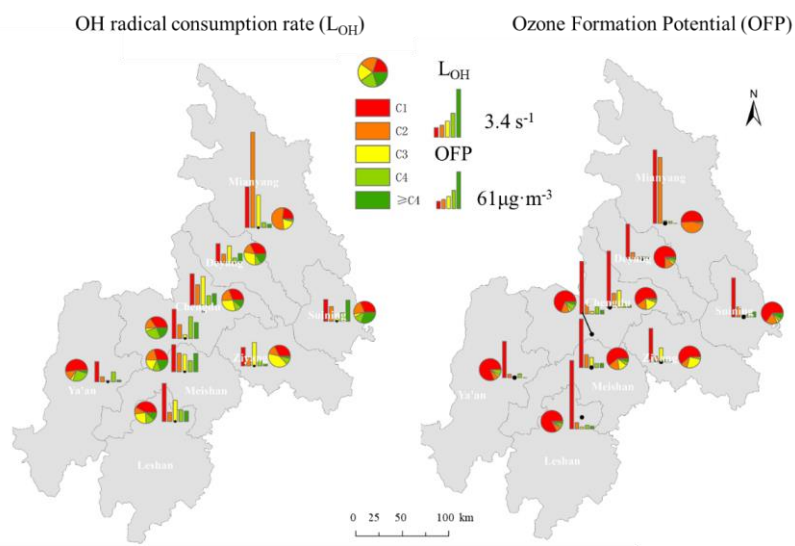

1343 **3.4 Atmospheric photochemical reactivity of carbonyl compounds**

1344 During the observation period, the total OH radical consumption rate (L_{OH}) and

删除了: The diurnal variation of the mixing ratio of ambient carbonyl compounds on weekdays and weekends in the eight cities of the CPUA is shown in Fig. S2. The total concentration of carbonyl compounds at each site on weekends was higher than that on weekdays, and the increase in carbonyl compounds at 0:00 (36.3%), 10:00 (16.3%) and 18:00-22:00 (17.6%) on weekends was higher than that on weekdays. Except for the XJ site, the increase in the concentration of carbonyl compounds at 0:00 on weekends was significantly higher than that on weekdays, which was mainly related to the increase of acetaldehyde, propionaldehyde and acetone on weekends. At 10:00, the higher increase at DY, CDHKY and SN sites was mainly related to the increase of propionaldehyde, acetaldehyde and formaldehyde concentrations. From 18:00 to 22:00, the higher increase at DY and YA sites was mainly related to the increase in the concentrations of propionaldehyde, acetone and acetaldehyde. Acetaldehyde, acetone and propionaldehyde were mainly from vehicle exhaust. In particular, when ethanol gasoline and biodiesel were used as alternative fuels, the content of acetaldehyde and acetone in the exhaust gas would be significantly increased. Therefore, the increase in the concentration of carbonyl compounds on weekends might be related to the increase in traffic at 10:00 and at night. In addition, the peak concentration of carbonyl compounds on weekends (10:00) was earlier than that on weekdays (12:00-14:00) at CDHKY, XJ and SN sites, and the diurnal trend of carbonyl compounds concentrations on weekdays and weekends had little difference at other sites.

1374 total ozone formation potential (OFP) of the 15 carbonyl compounds at each site are
 1375 depicted in Fig.5. The ranking of total L_{OH} and total OFP at each site is consistent,
 1376 except for the YA and ZY sites with lower concentrations of carbonyl compounds,
 1377 where the atmospheric photochemical reactivity ranking also aligns with the
 1378 concentration. Among all sites, the MY and CD sites display the highest reactivity,
 1379 while the YA and ZY sites exhibit the lowest reactivity. During the observation period,
 1380 carbonyl compounds significantly contributed to ozone formation. The contributions to
 1381 total VOCs (alkanes, alkenes, alkynes, aromatics, and carbonyl compounds) OFP at the
 1382 MY, SN, ZY, YA, and LS sites ranged from 19.5% to 48.6%. Formaldehyde and
 1383 acetaldehyde were identified as the most reactive species in the atmosphere, surpassing
 1384 other carbonyl compounds in reactivity due to their higher concentrations and inherent
 1385 reactivity, especially formaldehyde. However, acetone exhibited high inertness and a
 1386 prolonged atmospheric lifetime, leading to its accumulation in ambient air with
 1387 concentrations higher than other carbonyl compounds except for formaldehyde and
 1388 acetaldehyde. Thus, despite its elevated concentration, acetone's reactivity remained
 1389 relatively low.

删除了: Contrasting the L_{OH} and OFP during clean and polluted periods reveals higher values during ozone pollution periods than clean days. L_{OH} and OFP during different pollution periods show a strong positive correlation with the severity of ozone pollution; the heavier the ozone pollution, the higher the L_{OH} and OFP at the sites. Regardless of clean or polluted periods, the L_{OH} and OFP at the MY site are higher than other sites. However, despite this, the average ozone concentration at the MY site ranks lower among the nine sites observed. This might be associated with higher concentrations of aldehyde compounds at the MY site.

 1391 **Figure 5.** L_{OH} and OFP of carbonyl compounds at each site in the CPUA during the observation

1405 period

1406 3.5 Sensitivity analysis of ozone formation based on formaldehyde to NO₂ ratio (FNR)

1407 The change of O₃ formation sensitivity of each site in the CPUTA during the
1408 observation period is shown in Fig. 6. As can be seen from the Fig. 6, most sites remain
1409 in the VOCs-limited regime during the cleaning period and EP1 to EP3. Economically
1410 developed city such as Chengdu, Meishan, with high levels of formaldehyde and NO₂,
1411 remain in the VOCs-limited regime. Ya'an as a city with the lowest GDP ranking in the
1412 CPUTA, with low levels of formaldehyde and NO₂, remain in the transitional regime.

1413
1414 **Figure 6.** The change of O₃ formation sensitivity of each site in the CPUTA during the observation
1415 period. The arrows represent time step from clean period to EP1 to EP2 to EP3.

1416 The daily variation of O₃ formation sensitivity and ozone concentration at each
1417 site in the CPUTA during the observation period is shown in Fig. S4. The mean FNR of
1418 each site ranged from 0.48 to 1.29 during the observation period. The FNRs were lower
1419 than 0.55±0.16 at XJ, DY, ZY, CDHKY, and MS, and higher than 1.0 at LS, SN, YA
1420 and MY. At the same time, the mean ozone concentration at each site was between 138
1421 and 192 $\mu\text{g}\cdot\text{m}^{-3}$. The mean ozone concentration in XJ, DY, CDHKY and MS was 166-
1422 192 $\mu\text{g}\cdot\text{m}^{-3}$, it was 150-164 $\mu\text{g}\cdot\text{m}^{-3}$, in LS, SN, YA and MY. Therefore, it could be seen
1423 that most of the sites with high mean ozone concentrations during the observation

删除了: 3.9

删除了: $\mu\text{g}/\text{m}^3$

删除了: $\mu\text{g}/\text{m}^3$

1429 period, like CDHKY, XJ, MS and Deyan sites, were in the VOCs-limited regime, and
1430 most of the stations with low mean ozone concentrations during the observation period
1431 such as YA, SN, MY and LS were in the transitional regime. It was worth noting that
1432 the mean ozone concentration at ZY site (only 138 $\mu\text{g}\cdot\text{m}^{-3}$) during the observation
1433 period was much lower than that of other sites, but most of the ZY site was in VOCs-
1434 limited regime, which was mainly related to the low concentration of formaldehyde. In
1435 addition, the FNR value of the MY site was also relatively high, which was mainly
1436 caused by the high concentration of formaldehyde.

1437 Based on the ratio of formaldehyde to NO_2 mixing ratio, most sites remain in the
1438 VOCs-limited regime during the observation period. And the sites with heavy ozone
1439 pollution were in the VOCs-limited regime, and the sites with light ozone pollution
1440 were in the transitional regime. Photochemical reactivity (L_{OH} and OFP) analysis
1441 showed that formaldehyde and acetaldehyde contributed significantly to the
1442 enhancement of atmospheric oxidation and ozone formation potential. Therefore, when
1443 heavy ozone pollution occurs in the CPUA, special attention should be paid to the
1444 control of VOCs, especially formaldehyde and acetaldehyde in carbonyl compounds,
1445 under the coordinated control of NO_x and VOCs. Overall, this study reveals the
1446 important contribution of carbonyl compounds to ozone pollution in the CPUA, and
1447 provides scientific support for the establishment of ozone pollution prevention and
1448 control measures.

1449 3.6 Source Analysis of carbonyl compounds

1450 3.6.1 Quantitative source analysis of key carbonyl compounds

1451 The table S7 provides a summary of the background and primary emissions
1452 concentrations of formaldehyde, acetaldehyde, and acetone at nine sites across the eight
1453 cities of the CPUA, along with the proportion of secondary formation contributing to
1454 their concentrations. Background concentrations and primary emissions of
1455 formaldehyde, acetaldehyde, and acetone ranged from 50% to 80%, 46% to 83%, and

删除了: $\mu\text{g}/\text{m}^3$

1457 45% to 78%, respectively. Secondary formation accounted for 20% to 50%, 17% to
 1458 54%, and 22% to 55% of their concentrations, respectively. Notably, in SN and YA, the
 1459 secondary formation of formaldehyde contributed half of the observed concentration,
 1460 indicating it as the predominant source, while acetaldehyde's secondary formation also
 1461 prevailed in these sites. Conversely, acetone, with lower reactivity, primarily originated
 1462 from background concentrations and primary emissions at other sites except YA.
 1463 Moreover, background concentrations and primary emissions were identified as the
 1464 main contributors to carbonyl compounds in XJ and LS.

1465 Fig.7 illustrates the secondary formation concentrations of formaldehyde,
 1466 acetaldehyde, and acetone at each site in the CPUA under both clean and polluted
 1467 conditions. Under polluted conditions, the secondary concentrations of formaldehyde,
 1468 acetaldehyde, and acetone exceeded those in clean conditions by 58.8%, 54.6%, and
 1469 57.6%, respectively. The most significant increases in secondary concentrations were
 1470 observed at the SN site, while relatively smaller increases were observed at LS and XJ.

1471 **Figure 7.** Concentrations of formaldehyde, acetaldehyde and acetone in secondary formation
 1472 under different pollution conditions at each site in the CPUA during the observation period
 1473

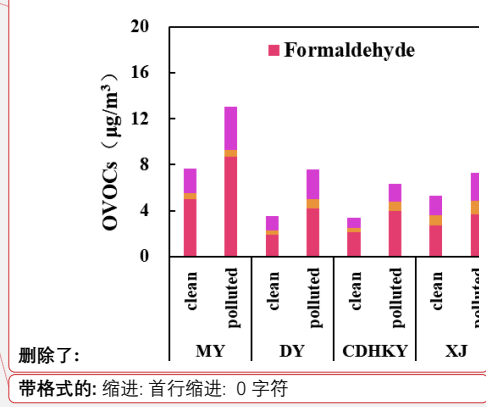

1474 **3.6.2 Exploration of secondary formation mechanism of key carbonyl compounds**

1475 In this study, we utilized VOC data collected on August 11, 12, and 16, when all
 1476 eight cities in the CPUA were experiencing mild to severe ozone pollution. We
 1477 calculated the Relative Incremental Reactivity (RIR) of formaldehyde, acetaldehyde,

删除了: The effects of anthropogenic source VOCs and plant source VOCs on the formation of formaldehyde, acetaldehyde and acetone at MY, SN, ZY, YA and LS sites were researched during a regional ozone pollution period when all 8 cities of the CPUA had mild or above ozone pollution (August 11th, 12th and 16th)

设置了格式: 非突出显示

1489 and acetone at the MY, SN, ZY, YA, and LS sites on these days. The OBM analysis
 1490 allowed us to assess the impact of anthropogenic VOCs (alkanes, alkenes, alkynes,
 1491 aromatics) and biogenic VOCs (e.g., isoprene) on carbonyl compound formation in the
 1492 context of regional ozone pollution events (Fig.8). Overall, the sensitivities of different
 1493 anthropogenic source and plant source VOCs to formaldehyde, acetaldehyde and
 1494 acetone was consistent among sites. For formaldehyde, reducing alkenes in
 1495 anthropogenic source VOCs and plant VOCs was the most effective way to control
 1496 formaldehyde concentration, while reducing alkenes in anthropogenic source VOCs
 1497 was also beneficial to reduce the formation of acetaldehyde. For acetone with low
 1498 reactivity, the alkanes in anthropogenic source VOCs were the most sensitive to the
 1499 formation of acetone, followed by alkenes and BVOCs. Only the RIR value of alkanes
 1500 were greater than zero, and the RIR values of both alkenes and BVOCs were less than
 1501 zero, indicating that reducing alkanes could reduce the formation of acetone, while
 1502 reducing alkenes and BVOCs was not conducive to acetone concentration control.

1503 **Figure 8.** Mean RIRs of formaldehyde, acetaldehyde and acetone to different anthropogenic

1508 3.6.3 Influence of regional transportation contribution

1509 The TrajStat trajectory model was used to calculate and cluster the 24-hour
1510 backward trajectories of air quality at the sampling sites. The backward trajectory
1511 during sampling is shown in Fig.S5. During the observation period, the pollution of
1512 carbonyl compounds in the cities of the CPUA was affected by the mutual transport
1513 among cities in Sichuan Province, especially along the MY-DY-CDHKY route. In
1514 addition, the surrounding provinces and cities of Sichuan Province (Gansu and
1515 Chongqing) also contributed to the carbonyl compounds of the CPUA.

删除了: 6

1516 The potential sources of carbonyl compounds at different pollution stages at the
1517 CDHKY during the observation period are shown in Fig. 9. It can be seen from the
1518 figure that there are differences in the potential sources of carbonyl compounds among
1519 different pollution stages at the CDHKY site. The concentration of local carbonyl
1520 compounds in CDHKY was high during the early observation period and EP1, which
1521 existed local sources, and was also affected by the northern airflow, and carbonyl
1522 compounds was also affected by the transport from MY, DY and other northern regions.
1523 Under the effect of the continuous northern airflow, the local source emissions
1524 decreased during EP1, and the potential source of carbonyl compounds changed to from
1525 the junction between CDHKY and ZY. During EP3, under the combined influence of
1526 the western airflow, the contribution of transport from SN and ZY to carbonyl
1527 compounds increased, while emissions from local sources also increased.

删除了: The potential sources of carbonyl compounds at different pollution stages at the Chengdu Institute of Environmental Sciences site during the observation period are shown in Fig. 9. It can be seen from the figure that there are differences in the potential sources of carbonyl compounds among different pollution stages at the CDHKY site. The concentration of local carbonyl compounds in CDHKY was high during the early observation period and EP1, which existed local sources, and was also affected by the northern airflow, and carbonyl compounds was also affected by the transport from MY, DY and other northern regions. Under the effect of the continuous northern airflow, the local source emissions decreased during EP1, and the potential source of carbonyl compounds changed to from the junction between CDHKY and ZY. During EP3, under the combined influence of the western airflow, the contribution of transport from SN and ZY to carbonyl compounds increased, while emissions from local sources also increased.

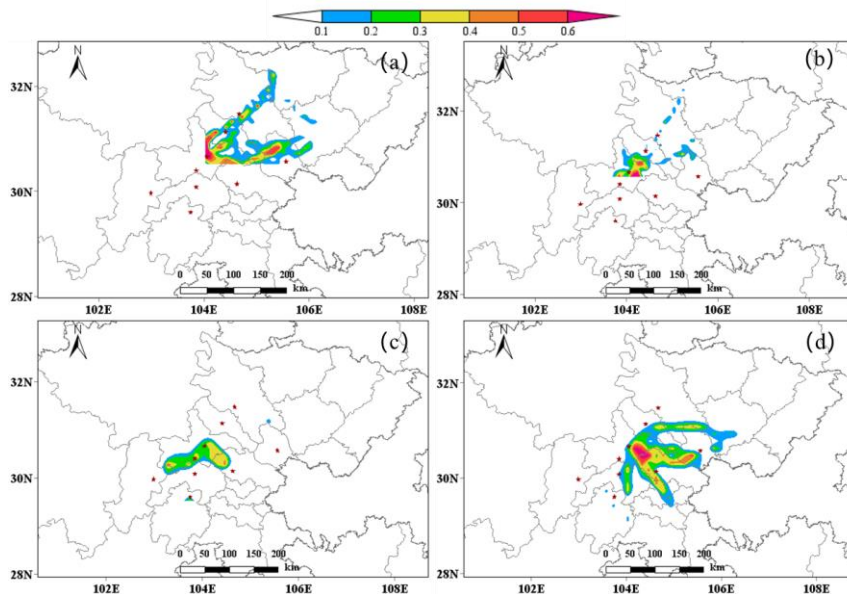

Figure 9. Analysis of potential sources of carbonyl compounds at different periods at the CDHKY site during the observation period (a) August 4th-6th (b) August 7th-9th (c) August 10th-13th (d) August 15th-18th

4. Conclusions

During a comprehensive atmospheric observation campaign conducted at nine sites across the CPUA from August 4th to 18th, 2019, three regional heavy ozone pollution episodes (EP1 to EP3), were observed. This study extensively examines the concentration variations, atmospheric chemical reactivity, and sources of carbonyls during this period. The average total concentrations of 15 carbonyl compounds across the nine sites within eight cities of the CPUA were measured at 17.4 ± 5.3 ppb. Spatial analysis indicated that areas with higher carbonyl concentrations were concentrated around Chengdu, extending both north and south. Notably, regions with elevated carbonyl compound concentrations also tended to experience more severe ozone pollution. Formaldehyde (36.4%-64.3%), acetone (12.4%-28.1%), and acetaldehyde (8.2%-47.3%) constituted the predominant species by volume concentration. Chengdu

1577 exhibited FAT concentrations surpassing national and international levels, indicating
1578 heightened levels compared to other regions.

1579 Compared to clean days, carbonyl compound concentrations were significantly
1580 higher on ozone pollution days, with increases ranging from 22.8% to 66.2%. Between
1581 19.5% and 48.6% of the total volatile organic compound (VOC) ozone formation
1582 potential (OFP) was attributed to the 15 carbonyl compounds, highlighting their
1583 substantial contribution to ozone formation, particularly formaldehyde and
1584 acetaldehyde. While primary emissions are the main sources of these compounds,
1585 secondary formation processes contributed over 30% on average to the concentrations
1586 of formaldehyde, acetaldehyde, and acetone. Under ozone pollution conditions, the
1587 secondary formation concentrations of these three compounds were notably higher than
1588 on clean days, with increases of 58.8%, 54.6%, and 57.6%, respectively, emphasizing
1589 the critical role of secondary processes in exacerbating regional ozone pollution. OBM

1590 modeling revealed that formaldehyde and acetaldehyde primarily originated from the
1591 secondary formation of alkenes and BVOCs, while acetone mainly stemmed from the
1592 secondary formation of alkanes. These findings highlight that while the concentration
1593 of carbonyl compounds is important, their significant impact on ozone formation is
1594 primarily driven by secondary chemistry. Specifically, the secondary formation of these
1595 compounds from alkenes and biogenic BVOCs plays a key role in this process.

1596 Ground-level observations of the formaldehyde to NO₂ ratio (FNR) were utilized
1597 to assess the sensitivity of ground-level ozone formation. Analysis of FNR revealed that
1598 sites experiencing heavy ozone pollution exhibited lower FNRs, indicating a VOCs-
1599 limited regime, while sites with lighter ozone pollution were categorized into a
1600 transitional regime. Furthermore, it is recommended to establish a scientific control
1601 mechanism for both NO_x and VOCs, with special attention to formaldehyde,
1602 acetaldehyde, and acetone, and their alkenes precursors. Additionally, considering the
1603 regional nature of pollution, this study suggests that carbonyl compound pollution is
1604 influenced by mutual transport among cities within the CPUA, notably along the MY-

删除了:

删除了: Diurnal variations showed peaks during the day and lows at night, with notable spikes on ozone pollution days. A distinctive "weekend effect" was observed, particularly evident in carbonyl compounds associated with motor vehicle emissions, such as acetaldehyde and acetone, peaking during morning rush hours and nighttime on weekends. This suggests significant contributions from both daytime photochemical processes and nighttime vehicular emissions to carbonyl compounds. At the MY site,
