20 **Abstract.** Gaseous carbonyl compounds serve as crucial precursors and intermediates  
21 in atmospheric photochemical reactions, significantly contributing to ambient ozone  
22 formation. To investigate the impact of gaseous carbonyls on regional ozone pollution,  
23 simultaneous field observations and observation-based modelling of ambient carbonyls  
24 were conducted at nine sites within the Chengdu Plain Urban Agglomeration (CPUA),  
25 China during August 4-18, 2019, when three episodes of regional heavy ozone pollution  
26 occurred across eight cities within CPUA. Throughout the study, the total mixing ratios  
27 of 15 carbonyls ranged from 10.70±4.16 to 35.18±13.37 ppbv, in which formaldehyde  
28 (48.1%), acetone (19.9%), and acetaldehyde (17.5%) were most abundant within the  
29 CPUA. Ambient levels of carbonyls and ozone showed some positive correlations in  
30 space (especially pronounced around Chengdu in both northern and southern directions)

31 and in diurnal variations with higher concentrations of carbonyls during ozone pollution  
32 episodes. Photochemical reactivity analysis emphasized the significant contributions of  
33 carbonyls, especially formaldehyde and acetaldehyde, to ozone formation. Sites with  
34 higher average ozone concentrations during observations were mainly in the VOCs-  
35 limited regime, while others were in the transitional regime. Local primary emissions,  
36 mutual air transportation among cities within the CPUA and photochemical secondary  
37 processes were recognized to contribute significantly to the production or the  
38 contamination of carbonyls in ambient air, with alkenes and alkanes being important  
39 precursors of secondary carbonyls. This study highlights the pivotal role of carbonyls  
40 in heavy ozone pollution within the CPUA, China, providing valuable scientific insights  
41 to guide the development of effective countermeasures for regional ozone pollution  
42 control in the future.

## 46 1. Introduction

47 Atmospheric carbonyl compounds play a pivotal role in tropospheric chemistry,  
48 acting as crucial precursors to both ozone ( $O_3$ ) and secondary organic aerosols (SOA),  
49 a fact recognized for decades (Altshuller, 1993; Grosjean and Seinfeld, 1989). Their  
50 importance has been confirmed by numerous studies over the years (Guo et al., 2004;  
51 Hallquist et al., 2009; Wang et al., 2020; Ye et al., 2021; Coggon et al., 2019),  
52 highlighting their significant contribution to atmospheric photochemistry and air  
53 pollution. Over the past two decades, severe air pollution in China has driven substantial  
54 research efforts to understand the contributions of carbonyl compounds to these  
55 environmental challenges. Studies have shown that photolysis of carbonyl compounds  
56 is a major source of  $RO_X$  radicals (Grosjean and Seinfeld, 1989; Zhang et al., 2016).  
57 These compounds can be photolyzed and react with OH radicals to form a large number  
58 of  $HO_2$  and  $RO_2$  radicals, which increase the atmospheric oxidation capacity and

59 participate in the NO<sub>x</sub> photochemical cycle, leading to ozone formation (Zhang et al.,  
60 2016; Meng et al., 2017). Additionally, dialdehydes such as glyoxal and methylglyoxal  
61 undergo heterogeneous reactions with aqueous particulate matter, rapidly forming SOA  
62 (Lou et al., 2010; Xue et al., 2016; Yuan et al., 2012). Ambient carbonyl compounds  
63 not only affect the environment but also pose direct health risks to humans. They can  
64 harm ecosystems through deposition and adsorption processes (Yang et al., 2018). They  
65 also pose direct health risks to humans, including sensitization, carcinogenesis, and  
66 mutagenicity (Fuchs et al., 2017).

67 Recent research has increasingly focused on understanding the spatial and  
68 temporal variability of carbonyl compounds in highly polluted regions, particularly in  
69 China, where rapid industrialization has led to severe air quality challenges. Xue et al.  
70 (2013) and Duan et al. (2012) reported typical ambient concentrations of carbonyl  
71 compounds ranging from a few  $\mu\text{g}\cdot\text{m}^{-3}$  to tens of  $\mu\text{g}\cdot\text{m}^{-3}$  in urban areas, depending on  
72 the specific compounds and regions studied. For example, formaldehyde concentrations  
73 in highly polluted areas can exceed  $10\ \mu\text{g}\cdot\text{m}^{-3}$ . Shen et al. (2013) and Fu et al. (2008)  
74 observed significant diurnal variation, with higher concentrations of carbonyl  
75 compounds during the daytime, particularly in the afternoon, driven by photochemical  
76 production. Concentrations can increase by as much as 50-100% during peak sunlight  
77 hours compared to nighttime levels. Pang and Mu (2006) and Rao et al. (2016)  
78 identified key sources of carbonyl compounds, including vehicular emissions, industrial  
79 activities, and secondary formation from VOC oxidation in the atmosphere. In urban  
80 environments, vehicular emissions are often a dominant primary source, while  
81 secondary formation contributes significantly during daytime due to photochemical  
82 processes. The results highlight severe and spatiotemporal variations of carbonyl  
83 pollution in China. High levels are found mainly in the North China Plain(NCP), the  
84 Yangtze River Delta(YRD), and the Pearl River Delta(PRD)(Duan et al., 2008; Shao et  
85 al., 2009; Tan et al., 2018; Wang et al., 2018; Xue et al., 2014, 2013; Yang et al., 2017).  
86 Urban areas generally exhibit higher carbonyl levels than suburban and rural areas due

87 to human activities(Xue et al., 2013). Despite the progress made, significant gaps  
88 remain in understanding the spatiotemporal distribution and source apportionment of  
89 carbonyl compounds, particularly in urban agglomerations. Existing research has  
90 primarily focused on urban areas in rapidly developing regions like the NCP, YRD, and  
91 PRD. Moreover, studies have often emphasized the overall role of VOCs in ozone  
92 pollution, with less attention given to specific carbonyl compounds and their individual  
93 contributions to atmospheric oxidation capacity and ozone formation (Meng et al.,  
94 2017).

95 Monitoring carbonyl compounds in the atmosphere is challenging due to their  
96 typically low concentrations (ppt-ppb levels), necessitating highly sensitive analytical  
97 methods. The diversity of carbonyl compounds, including multiple isomers, requires  
98 highly selective analytical techniques for differentiation. Current measurement  
99 technologies limit our understanding of the spatiotemporal distribution of carbonyl  
100 compounds, affecting the accurate assessment of their environmental behavior, sources,  
101 and transport (Xue et al., 2013; Sahu and Saxena, 2015). While numerous studies have  
102 explored the role of carbonyl compounds in ozone production, many focus on general  
103 mechanisms rather than specific compounds or regional variations (Atkinson and Arey,  
104 2003; Monks et al., 2015).

105 Atmospheric carbonyl compounds originate from both primary and secondary  
106 sources (Pang and Mu, 2006; Rao et al., 2016). Primary sources include the incomplete  
107 combustion of fossil fuels and biomass, industrial emissions, emissions from the  
108 catering industry, and releases from plants. Secondary sources arise from the  
109 atmospheric photochemical oxidation of VOCs (Xue et al., 2013), particularly  
110 alkenes, aromatics, and isoprene, which typically dominate the secondary formation of  
111 carbonyls. However, distinguishing between primary and secondary contributions  
112 remains challenging. Existing source apportionment methods, such as characteristic  
113 species ratios and multiple linear regression, often lack the resolution to differentiate  
114 these sources accurately, especially for non-vehicular emissions and secondary

115 formation. The limitations of these methods underscore the need for more advanced  
116 approaches to better quantify the secondary formation mechanisms of carbonyl  
117 compounds and their regional impact on ozone formation. Despite significant  
118 advancements in studying atmospheric carbonyls, key gaps remain in understanding  
119 their precise spatiotemporal distribution and source apportionment. Specifically, there  
120 is a need for studies that examine how carbonyls vary across different environments—  
121 urban, suburban, and rural—and during varying pollution events. Without such targeted  
122 analysis, our understanding of the behavior of carbonyl compounds and their  
123 contribution to ozone pollution remains incomplete, particularly in regions  
124 experiencing severe pollution.

125 In this context, this study focuses on atmospheric carbonyl compounds and their  
126 roles in photochemical pollution within the Chengdu Plain Urban Agglomeration  
127 (CPUA) of China. The CPUA includes eight cities: Chengdu, Mianyang, Deyang,  
128 Leshan, Meishan, Yaan, Suining, and Ziyang. This region has a developed economy  
129 and a high degree of internationalization. The CPUA is located on the western edge of  
130 the Sichuan Basin, surrounded by mountain ranges, which easily block airflow. The  
131 unique climatic environment of the CPUA features low wind speeds year-round, high  
132 frequency of static winds, short hours of sunshine, frequent winter inversions, and a  
133 pronounced heat island effect in summer. These climatic characteristics significantly  
134 impact the variations in air pollutant concentrations, making the region prone to ozone  
135 pollution in summer and haze pollution in winter. (Li et al., 2013; Hu et al., 2017; Zhang  
136 et al., 2010). Although previous studies have shown that ozone formation in urban  
137 Chengdu is primarily VOCs-limited (Tan et al., 2018), with aromatic hydrocarbons and  
138 alkenes contributing significantly to ozone generation in summer (Xu et al., 2020),  
139 these studies mainly focus on single cities and overall VOCs. There is limited  
140 understanding of the distribution, sources, and specific roles of carbonyl compounds  
141 across the entire CPUA and their contributions to regional ozone pollution and mutual  
142 air transport mechanisms.

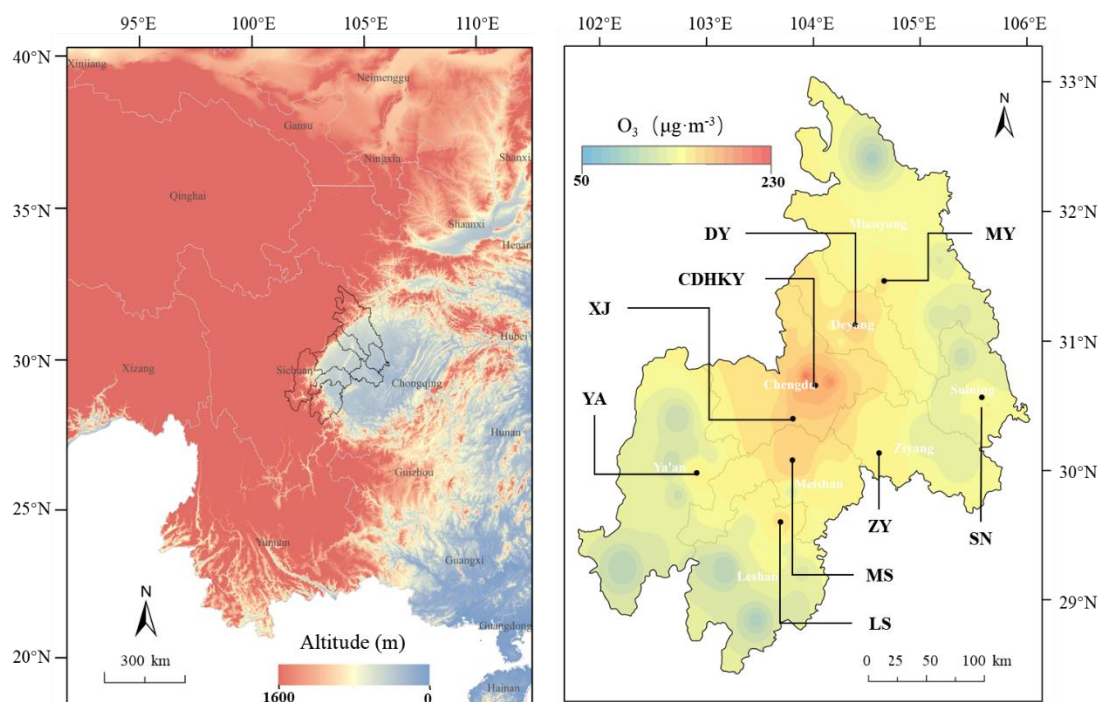

143 To address these research gaps, this study involves an intensive field observation  
144 experiment conducted by the Sichuan Academy of Environmental Sciences, Peking  
145 University, Sichuan University and Chinese Academy of Environmental Sciences.  
146 Atmospheric carbonyl compounds were observed at nine sites in eight cities within the  
147 CPUA for 15 days during a period of heavy ozone pollution in August 2019. Samples  
148 were analyzed using 2,4-dinitrophenylhydrazine solid phase adsorption/high  
149 performance liquid chromatography (HPLC). The study aims to characterize the  
150 atmospheric carbonyl compounds in the CPUA, assess their influence on  
151 photochemical pollution, identify key carbonyl compounds that may play crucial roles  
152 in heavy ozone pollution in the CPUA, and evaluate the contribution of primary  
153 emissions, air pollution transport, and secondary generation to key carbonyl compounds  
154 through a combination of multivariate linear regression modeling and Observation-  
155 Based Modeling (OBM). This research aims to provide technical support for controlling  
156 carbonyl compounds pollution in the CPUA and to reduce their contributions to ozone  
157 pollution.

## 158 **2. Materials and methods**

### 159 **2.1 Observation Sites Profile**

160 In this study, a total of 9 off-line sampling sites for atmospheric carbonyl  
161 compounds were set up in 8 cities in the CPUA from August 4<sup>th</sup> to 18<sup>th</sup>, 2019(table S1).  
162 Considering that this study focused on the pollution characterization of carbonyl  
163 compounds in urban areas, one urban site was selected in each city. In addition, in order  
164 to compare and study the pollution characteristics of carbonyl compounds in the  
165 suburbs, a suburban site was set up in Xinjin County, Chengdu. For the selection of  
166 urban sites in each city, priority is given to those choices of set-up in the vicinity of the  
167 state-controlled site, and the perimeter of the sites should be open, unobstructed and no  
168 obvious pollution sources, with convenient transportation and power supply. The  
169 distribution of specific sites is shown in Fig. 1.

170 Ozone concentrations were measured using the UV absorption method with a  
 171 Thermo O<sub>3</sub> analyzer (Model 49i), with data sourced from national control stations near  
 172 each sampling site. Nitrogen dioxide (NO<sub>2</sub>) was measured by chemiluminescence  
 173 following chemical conversion to nitric oxide (NO) using a molybdenum catalyst;  
 174 however, this method is known to have interferences from other NO<sub>x</sub> species. Carbon  
 175 monoxide (CO) was measured via infrared absorption with a Thermo instrument  
 176 (Model 20). All Thermo instruments were carefully maintained and calibrated daily at  
 177 01:00 to ensure measurement accuracy. Measurements for ozone, NO<sub>2</sub>, and CO were  
 178 collected with a time resolution of one hour. Simultaneously, meteorological  
 179 parameters—temperature, relative humidity (RH), wind speed, and direction—were  
 180 recorded at each observation site using an automatic weather station (PC-4, JZYG,  
 181 China), also at a one-hour resolution.

182  
 183 **Figure 1.** Distribution of sampling sites. The left panel shows the elevation map of the Sichuan  
 184 Basin, highlighting the geographical features of the region, with elevation data sourced from the  
 185 Geospatial Data Cloud (<https://www.gscloud.cn/#page1/2>). The right panel presents the spatial  
 186 distribution of ozone concentrations in the CPUA during the observation period (August 4–18,  
 187 2019), with ozone data obtained from national control stations near each sampling site. Black dots  
 188 represent the locations of the sampling sites, labeled as follows: MY (Mianyang), DY (Deyang),  
 189 CDHKY (Chengdu Environmental Science Research Institute), XJ (Xinjin), SN (Suining), ZY

190 (Ziyang), MS (Meishan), YA (Ya'an), and LS (Leshan). The color bar in the top left corner  
191 corresponds to interpolated ozone concentrations, with each color representing a concentration  
192 gradient.

## 193 2.2 Samples Collection

194 The sampling of atmospheric carbonyl compounds mainly referred to the TO-11A  
195 standard of the United States Environmental Protection Agency (US EPA) and the  
196 Chinese environmental protection standard HJ 683-2014 High Performance Liquid  
197 Chromatography Method for the Determination of Atmospheric Carbonyl Compounds,  
198 and the sampling was carried out by using silica gel sampling tubes (IC-DN3501 from  
199 Tianjin Bonna-Agela) coated with DNPH (2,4-dinitrophenylhydrazine). In this study,  
200 an automatic sampler for carbonyl compounds (Zhang et al., 2019) was used to  
201 continuously collect atmospheric carbonyl compounds. From August 4th to 18th, 2019,  
202 air samples were collected every 2 hours with a sampling flow rate of  $0.8 \text{ L} \cdot \text{min}^{-1}$ . In  
203 addition, in order to prevent the impact of ozone and rainwater in the atmospheric air  
204 on sample collection, a potassium iodide ozone removal column (KI 140 from Tianjin  
205 Bonna-Agela) was installed and a water removal agent made by ourselves (Bao et al.,  
206 2022; Wang et al., 2020) was added at the front end of the sample tube. Two blank  
207 samples were collected before and after the sampling, and blank samples were also  
208 collected for different batches of sampling tubes. The samples were frozen at  $-18^{\circ}\text{C}$  and  
209 analyzed within one month.

210 Atmospheric VOCs were sampled using SUMMA tanks, stainless steel tanks with  
211 electropolished and silanized inner walls, manufactured by Entech in the United States,  
212 with a sampling volume of 3.2 liters. The sampling was controlled by a constant current  
213 integral sampler to sampling for an average of 1 hour. From August 4<sup>th</sup> to 18<sup>th</sup>, 2019,  
214 two VOCs samples were collected each day at each site, at 8:00-9:00 and 14:00-15:00  
215 (no samples were taken under special weather conditions, such as rain). On August 11<sup>th</sup>,  
216 12<sup>th</sup> and 16<sup>th</sup>, six samples were collected per day to capture diurnal variations under  
217 ozone pollution events, at the following times: 8:00-9:00, 10:00-11:00, 12:00-13:00,  
218 14:00-15:00, 16:00-17:00, and 18:00-19:00.

### 219 2.3 Samples Analysis

220 The carbonyl compounds samples were qualitatively and quantitatively analyzed  
221 by using High Performance Liquid Chromatography (HPLC) (LC-20AD, Shimadzu,  
222 Japan) and an ultraviolet detector (SPD-20A, Shimadzu, Japan), mainly based on the  
223 US EPA TO-11A standard and the Chinese HJ 683-2014 standard. The DNPH sampling  
224 column after sampling was slowly eluted into a volumetric flask using acetonitrile  
225 (chromatographically pure, Thermo Fisher Scientific China) to 5.0 mL. Then 1.5 mL  
226 sample was taken into an HPLC sample bottle, and sealed and stored in a refrigerator  
227 at <4 °C to complete the pre-treatment. Prior to sample analysis, a standard solution of  
228 the concentration gradient was prepared using TO-11A standard solution (Supelco,  
229 USA) and used as the external standard. The correlation coefficient ( $R^2$ ) of the standard  
230 curve was greater than 0.995. The limit of detection of the device was 0.56~5.57  
231  $\text{ng}\cdot\text{mL}^{-1}$ , and the limit of quantification was 1.87~18.56  $\text{ng}\cdot\text{mL}^{-1}$  (Table S2). Then 20  
232  $\mu\text{L}$  of the pretreated sample was extracted through the autosampler and injected into the  
233 HPLC/UV system, detected by a UV detector with a wavelength of 360 nm, qualified  
234 by retention time value, quantified by peak area value, and the qualitative and  
235 quantitative analysis data of carbonyl compounds were obtained after conversion. The  
236 HPLC conditions referred to Chinese environmental protection standard HJ 683-2014:  
237 binary gradient washing was performed using acetonitrile and water, 60% acetonitrile  
238 was held for 20 mins, acetonitrile was increased linearly from 60% to 100% within 20-  
239 30 mins, and acetonitrile was reduced to 60% again within 30-32 mins and held for 8  
240 mins; the column oven was kept at 40 °C.

241 The atmospheric VOCs were analyzed using the TO-14 and TO-15 methods,  
242 which are recommended by the US EPA. These methods involve frozen  
243 preconcentration coupled with gas chromatography and mass spectrometry (GC-MS).  
244 TO-15 is a method for detecting and quantifying a wide range of VOCs from air samples.  
245 The VOCs were pre-concentrated by the Entech7100 system at a low temperature, then  
246 quantified by an Agilent GC-MS. During the sample analysis, four internal standard

247 gases (bromochloromethane, 1,4-difluorobenzene, chlorobenzene-d5, and 4-  
248 bromofluorobenzene) were used. A multi-point calibration curve was created using a  
249 standard gas containing 118 VOCs, including PAMS compounds, TO-15 target analytes,  
250 and carbonyl compounds. PAMS (Photochemical Assessment Monitoring Stations)  
251 compounds are a subset of hydrocarbons known to contribute to ozone formation, such  
252 as ethane, ethylene, propane, and others."

## 253 **2.4 Data Analysis**

### 254 **2.4.1 Ozone pollution assessment criteria**

255 According to the Technical Regulation on Ambient Air Quality Index (on trial),  
256 National Environmental Protection Standard of the People's Republic of China HJ  
257 633—2012, days with an ozone pollution index (IAQI) of 100 or higher during the  
258 observation period were designated as pollution days, while days with an IAQI below  
259 100 were considered clean days. This study compared the pollution characteristics of  
260 carbonyl compounds between pollution days and clean days. Additionally, the  
261 concentrations of formaldehyde, acetaldehyde, and acetone observed during the  
262 summer of 2009-2013 in economically developed and industrialized areas such as  
263 Beijing, Shanghai, and Guangzhou in China, as well as locations in South America  
264 (Brazil), Asia (Thailand), Europe (France), and North America (United States), were  
265 selected and compared.

### 266 **2.4.2 Ozone formation sensitivity**

267 Previous studies have shown that the formaldehyde to NO<sub>2</sub> ratio (FNR) can be  
268 used to determine the sensitivity of O<sub>3</sub>-NO<sub>x</sub>-VOCs (Schroeder et al., 2017; Tonnesen  
269 and Dennis, 2000; Vermeuel et al., 2019). Most studies used satellite remote sensing-  
270 based FNR, but the FNR column concentration ratios inverted by satellite remote  
271 sensing mainly represented the average photochemical of the troposphere, and the  
272 concentration distributions of HCHO and NO<sub>2</sub> in the vertical direction were

273 inconsistent (Hong et al., 2022; Schroeder et al., 2017). So, there is a large uncertainty  
274 to develop ground-level ozone pollution prevention and control measures. In this study,  
275 sensitivity analysis of ground-level ozone formation was carried out based on the ratio  
276 of ground-level HCHO to NO<sub>2</sub> during the observation period at the 9 sites of 8 cities in  
277 the CPUA. FNR < 0.55±0.16 and FNR > 1.0±0.3 were defined to VOCs-limited and  
278 NO<sub>x</sub>-limited, respectively, and FNR ratio ranged from 0.55±0.16 to 1.0±0.3 defined to  
279 NO<sub>x</sub> and VOCs co-limited (Liu et al., 2021; Zhang et al., 2022).

### 280 2.4.3 Exploration of Secondary Formation Mechanisms

#### 281 (1) Atmospheric chemical reactivity

282 In this study, the contribution of atmospheric chemical reactivity of carbonyl  
283 compounds to ozone formation was evaluated using the OH free radical consumption  
284 rate (L<sub>OH</sub>) and ozone formation potential (OFP):

$$285 \quad L_{OH} = [\text{OVOC}]_i \times k_i(\text{OH}) \quad (1)$$

286 Where, [OVOC]<sub>i</sub> was the observed concentration of the i<sup>th</sup> (i=1 to n) carbonyl  
287 compound, in molecule·cm<sup>-3</sup>; k<sub>i</sub>(OH) was the rate constants of the i<sup>th</sup> carbonyl  
288 compound reacting with OH radicals, in cm<sup>3</sup>·(molecule·s)<sup>-1</sup>. The unit of L<sub>OH</sub> is s<sup>-1</sup>,  
289 representing the rate of OH radical consumption. The selected k<sub>i</sub>(OH) values were from  
290 literature (Atkinson and Arey, 2003).

$$291 \quad \text{OFP} = \text{MIR}_i \times [\text{OVOC}]_i \quad (2)$$

292 Where, MIR was the maximum incremental reactivity of the i<sup>th</sup> carbonyl  
293 compound, in g O<sub>3</sub>·(g VOC)<sup>-1</sup> (grams of ozone formed per gram of volatile organic  
294 compound), and the MIR values of each species were from California Code of  
295 Regulations (<https://govt.westlaw.com>); [OVOC]<sub>i</sub> was the mass concentration of the i<sup>th</sup>  
296 carbonyl compound, in µg·m<sup>-3</sup>. The unit of OFP is µg·m<sup>-3</sup>, representing the potential  
297 ozone formation.

#### 298 (2) Observation-based model (OBM)

299 The Observation-Based Model (OBM) is a box model that uses actual  
300 observational data to evaluate the sensitivity of secondary pollutant formation  
301 mechanisms to their precursor emissions. By constraining the model with atmospheric  
302 observation data, typical secondary pollutants and parameters such as NO<sub>x</sub>, SO<sub>2</sub>, CO,  
303 VOCs, temperature, humidity, pressure, and JNO<sub>2</sub> are input into the model as hourly  
304 observational data to calculate the chemical formation and consumption of secondary  
305 pollutants and free radicals. In this study, the OBM model used the Master Chemical  
306 Mechanism (MCM) (v3.3.1, mcm.leeds.ac.uk), which is a nearly detailed chemical  
307 mechanism that describes the chemical processes of 143 VOC species from emission  
308 to degradation in the atmosphere, including approximately 6,700 species and 17,000  
309 inorganic and organic reactions. The MCM chemical mechanism can simulate  
310 atmospheric photochemical reaction processes under near-real conditions and calculate  
311 the concentrations of highly reactive species, quantifying the reaction rates of all  
312 species involved.

313 Relative Incremental Reactivity (RIR) was first used by Cardelino and Chameides  
314 (1995) to simulate the response of ozone to precursor changes through scenario tests  
315 using box model calculations. RIR was calculated by assuming that the concentration  
316 of a given carbonyl compound precursor decreased by a certain proportion could cause  
317 the change of the concentration of the carbonyl compound, so as to further judge the  
318 effect of VOCs on the formation of carbonyl compounds. Combining the concentrations  
319 and activity levels of 15 carbonyl compounds during the observation period, this study  
320 focused on formaldehyde, acetaldehyde, and acetone as the primary research targets.  
321 The impacts of various AVOCs (anthropogenic VOCs), including alkanes, alkenes,  
322 alkynes, and aromatic hydrocarbons, as well as BVOCs (biogenic VOCs) like isoprene,  
323 on the formation of formaldehyde, acetaldehyde, and acetone were assessed using  
324 observation-based OBM classification. Specific species of anthropogenic source VOCs  
325 (alkanes, alkenes, alkynes, and aromatic hydrocarbons) and biogenic VOCs (isoprene)  
326 are detailed in Table S3.

327 VOCs observations, conventional gases (NO<sub>2</sub>, CO and SO<sub>2</sub>) and meteorological  
328 parameters (temperature, relative humidity and pressure) were imputed into the model.  
329 It was assumed that the pollutants are well mixed. Under the constraints of the measured  
330 hourly concentration data of pollutants, the atmospheric chemical process was  
331 simulated to obtain the source-effect relationship of the measured pollutants. By  
332 assuming the reduction of the source effect, the RIRs of different carbonyl compounds  
333 precursors were calculated, and the sensitivities of carbonyl compounds to different  
334 pollutants were obtained, and then the secondary formation mechanism of carbonyl  
335 compounds was determined. The formula to calculate the RIR is as follows:

$$336 \quad RIR(X) = \left[ \frac{\Delta P_Y(X)/P_Y(X)}{\Delta S(X)/S(X)} \right] \quad (3)$$

$$337 \quad P_Y = Y_{\text{net formation}} - Y_{\text{net consumption}} \quad (4)$$

338 Where X was a specific species; P<sub>Y</sub>(X) was the net formation rate of species y;  
339 S(X) was the total amount of emissions of species X in a certain period, i.e., the source  
340 effect of species X. ΔS(X) was the change in total emissions of X caused by the  
341 hypothetical change in source effect, ΔP<sub>Y</sub>(X) was the change in P<sub>Y</sub>(X) after the change  
342 in source effect S(X), and RIR(X) was the relative incremental reactivity of species X.  
343 The species Y in this study were formaldehyde, acetaldehyde and acetone, respectively,  
344 and pollutant X was reduced by 20%.

345 The absolute RIR of the precursor reflects the sensitivity of carbonyl compounds  
346 formation to the precursor. The higher the absolute RIR, the more sensitive the carbonyl  
347 compounds formation to the precursor. A positive RIR value indicates that reducing the  
348 species can reduce the formation rate of species Y, and a negative RIR value indicates  
349 that reducing the species can increase the formation rate of species Y.

#### 350 2.4.4 Sources Analysis

##### 351 (1) Multi-linear regression model

352 There is a good correlation between concentrations of compounds of the same or

353 similar source in the atmosphere. Based on this property, it was assumed that the  
 354 primary and secondary sources of carbonyl compounds were linearly correlated with  
 355 the selected tracers, and then a quantitative source model was established by multiple  
 356 linear statistical regression analysis (Kanjanasiranont et al., 2016a; Li et al., 2010; Ling  
 357 et al., 2017; Luecken et al., 2012; Lui et al., 2017; Wang et al., 2017). In general, CO is  
 358 the marker product of typical anthropogenic combustion source emissions, mainly from  
 359 vehicle exhaust emissions and coal combustion. Ozone, as an indicator of  
 360 photochemical smog, is a typical secondary formation pollutant. In this study, CO and  
 361 ozone were selected as the tracers of primary source and secondary source of carbonyl  
 362 compounds, respectively. The formula is as follows:

$$363 \quad [carbonyl] = \beta_0 + \beta_1[CO] + \beta_2[O_3] \quad (6)$$

364 Where [carbonyl], [CO] and [O<sub>3</sub>] represented the observed mixing ratios of  
 365 carbonyl compounds, CO and ozone, respectively, in ppbv.  $\beta_0$ ,  $\beta_1$  and  $\beta_2$  were  
 366 coefficients obtained by multiple linear regression fitting model, in ppbv/ppbv.  $\beta_0$   
 367 represented the background concentration of a given carbonyl compound,  $\beta_1$   
 368 represented the emission ratio of the carbonyl compound relative to CO.  $\beta_1[CO]$  and  
 369  $\beta_2[O_3]$  represented the concentrations of carbonyl compound in primary emission and  
 370 secondary formation, respectively, in ppbv.

371 In addition, the relative contribution of primary emissions, secondary formation  
 372 and background concentrations of carbonyl compounds can be calculated using the  
 373 following formula:

$$374 \quad P_{primary} = \frac{\beta_1[CO]_i}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (7)$$

$$375 \quad P_{secondary} = \frac{\beta_2[O_3]_i}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (8)$$

$$376 \quad P_{background} = \frac{\beta_0}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (9)$$

377 Where,  $P_{primary}$  represented the contribution of the primary emission of a given  
 378 carbonyl compound, %;  $P_{secondary}$  represented the contribution of the secondary  
 379 formation of the carbonyl compound species, %;  $P_{background}$  represented the contribution

380 of the carbonyl compounds species from sources other than primary emissions and  
381 secondary formation, %.

## 382 (2) Backward trajectory model

383 The effects of long-distance air mass transport on the pollution of carbonyl  
384 compounds in the CPUA were studied using MeteoInfo software and TrajStat plug-in  
385 (<http://www.meteothink.org/downloads/index.html> ). In this model, meteorological  
386 data were relevant meteorological data from the global data assimilation system (GDAS)  
387 database (<ftp://arlftp.arlhq.noaa.gov/pub/archives/gdas1>). A trajectory simulation height  
388 of 500 m was selected. The duration of backward trajectory was 48 h. The daily start  
389 time was 00:00 UTC. The analog frequency was 2 h. The backward trajectory diagram  
390 was calculated. Meanwhile, the clustering method in TrajStat software and the  
391 Euclidean distance algorithm were used to cluster the airflow trajectory to the CPUA.  
392 And then the statistical analysis was carried out in combination with the corresponding  
393 pollutant mass concentration characteristics.

## 394 3. Results and Discussion

### 395 3.1 Overview of air quality during observation period

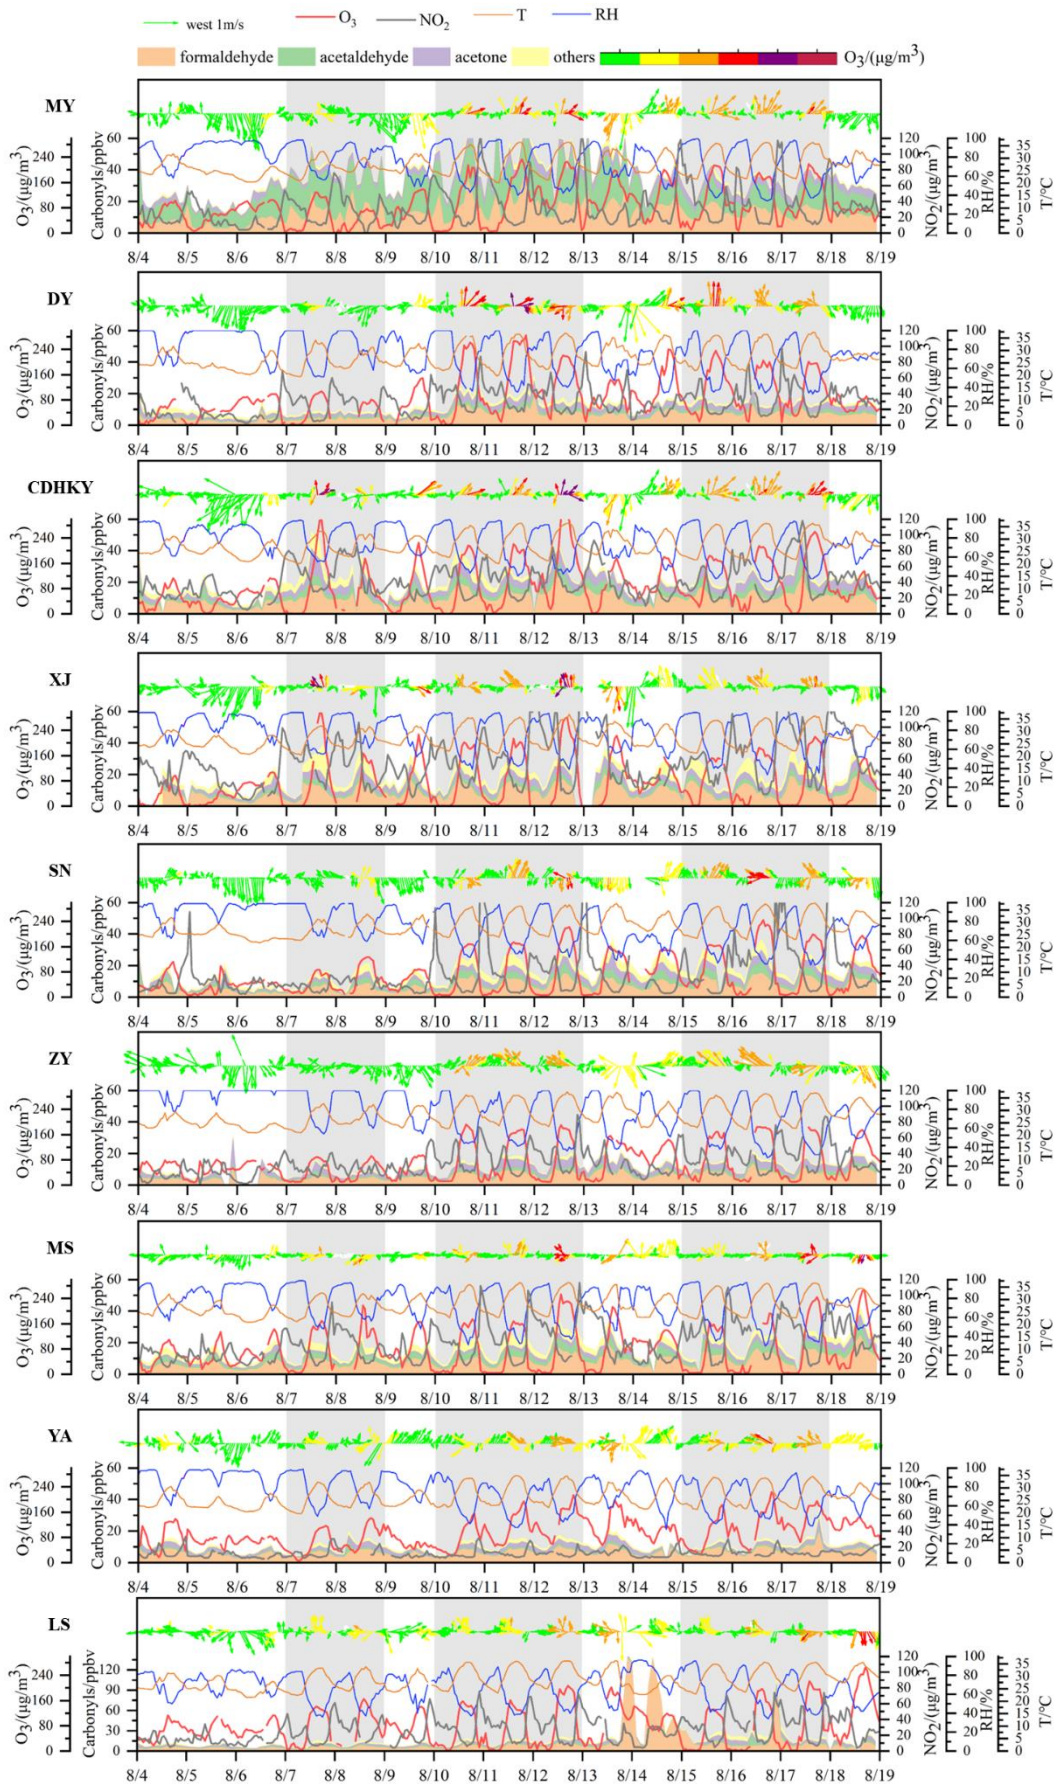

396 Due to the influence of cooling and precipitation caused by cold air intrusion, the  
397 early observation period (from August 4<sup>th</sup> to 6<sup>th</sup>, 2019) in the Chengdu Plain Urban  
398 Agglomeration (CPUA) experienced slightly lower temperatures (25.1°C) and higher  
399 humidity (87.6%). These conditions were unfavorable for ozone formation. Although  
400 ozone itself is not easily removed by rain, precipitation reduces ozone pollution by  
401 washing away its precursors, such as nitrogen oxides (NO<sub>x</sub>) and volatile organic  
402 compounds (VOCs), decreasing sunlight exposure, and enhancing atmospheric  
403 dispersion. However, as temperatures increased and humidity dropped in the  
404 subsequent days, more favorable conditions for ozone formation emerged, leading to  
405 heavy and persistent regional ozone pollution in the CPUA. By August 12<sup>th</sup>, the mean

406 temperature had gradually increased to 29.1°C, while it averaged 27.7°C from August  
407 13<sup>th</sup> to 14<sup>th</sup>. During this time, cumulative precipitation reached 975 mm, resulting in  
408 temporary alleviation of ozone pollution. Subsequently, temperatures rose again from  
409 August 15<sup>th</sup> to 18<sup>th</sup>, with the mean temperature persisting above 28.4°C for several days,  
410 accompanied by a decrease in humidity to a minimum of 64.8% on August 17<sup>th</sup>. Overall,  
411 during the observation period (from August 4<sup>th</sup>, 2019, 0:00 to August 18<sup>th</sup>, 2019, 24:00),  
412 three episodes of severe ozone pollution occurred, namely EP1 (August 7<sup>th</sup> to 9<sup>th</sup>), EP2  
413 (August 10<sup>th</sup> to 13<sup>th</sup>), and EP3 (August 15<sup>th</sup> to 18<sup>th</sup>), as depicted in Fig. 2.

414 Fig.3 illustrates the temporal and spatial variations of ozone and NO<sub>2</sub>  
415 concentrations, as well as temperature and humidity at each site during the observation  
416 period. After observing the spatial distribution of ozone concentration during EP1, it's  
417 evident that the severity of pollution reached heavily polluted levels, with Chengdu  
418 recording an MDA8 concentration of 297  $\mu\text{g}\cdot\text{m}^{-3}$  on August 7<sup>th</sup>. This distribution  
419 demonstrated a radial decrease from Chengdu to the surrounding areas. However, the  
420 subsequent episodes, EP2 and EP3, exhibited even broader ranges of ozone pollution  
421 and more pronounced spatial movements. During the early stages of EP2 and EP3 (from  
422 August 10<sup>th</sup> to 11<sup>th</sup> and from August 14<sup>th</sup> to 15<sup>th</sup>, respectively), high ozone  
423 concentrations were observed in the Chengdu-Deyang-Mianyang region. In the middle  
424 stages (August 12<sup>th</sup> and from August 16<sup>th</sup> to 17<sup>th</sup>, respectively), influenced by northerly  
425 airflow, regions with high ozone concentrations expanded to the central (Meishan,  
426 Ziyang, and Suining) and southwestern (Leshan and Ya'an) parts of the CPUA. In the  
427 later stages (August 13<sup>th</sup> and August 18<sup>th</sup>), under the influence of northwesterly airflow,  
428 regions with high ozone concentrations (Meishan and Leshan) moved southward again,  
429 while ozone pollution in other areas of the CPUA gradually weakened. On August 11<sup>th</sup>  
430 to 12<sup>th</sup> and August 16<sup>th</sup> to 17<sup>th</sup>, ozone concentrations in the eight cities of the CPUA  
431 reached light pollution levels or higher, with the heaviest pollution recorded on August  
432 12<sup>th</sup>. Specifically, Deyang, Mianyang, Suining, and Meishan reached moderate  
433 pollution levels, while Chengdu reached heavy pollution with a concentration of 324

434  $\mu\text{g}\cdot\text{m}^{-3}$ .

435

436 **Figure 2.** Overview of air quality at each site during the observation period. The gray shaded parts  
437 respectively represent the three heavy ozone pollution episodes (EP1, EP2,EP3).

438  
439 **Figure 3.** Temporal and spatial variations of (a) ozone concentration, (b) NO<sub>2</sub> concentration, (c)  
440 temperature and (d) humidity in the CUPA during the observation period.

### 441 3.2 Comparative characterization of carbonyl compounds

#### 442 3.2.1 Ambient levels

443 During the observation period, we utilized 2,4-dinitrophenylhydrazine (DNPH)  
444 cartridge and high-performance liquid chromatography (HPLC) analysis technique to  
445 quantify 15 carbonyl compounds. The concentrations and relative proportions of these  
446 compounds are summarized in Table 1. The average total concentration of the 15  
447 carbonyls in the CUPA was  $17.35 \pm 5.31$  ppb. Overall, areas with elevated  
448 concentrations of carbonyl compounds were primarily concentrated in and around  
449 Chengdu in both northern and southern directions. MY site, located to the north of  
450 Chengdu, exhibited the highest concentration of carbonyl compounds ( $35.18 \pm 13.37$

451 ppb), while YA site, situated southwest of Chengdu, showed the lowest concentration  
 452 ( $10.70 \pm 4.16$  ppb).

453

454 **Table 1.** Daily mean  $\pm$  standard error of carbonyl compound mixing ratios (ppbv) at each site in  
 455 the CPUA during the observation period. Sum: the total sum of carbonyl compound mixing ratios  
 456 across all compounds at each site.

Carbonyls	MY	DY	CDHKY	XJ	SN	ZY	MS	YA	LS

<b>Sum</b>	35.18 $\pm$ 13.37	12.16 $\pm$ 4.84	20.84 $\pm$ 8.85	19.04 $\pm$ 8.1	16.05 $\pm$ 7.73	11.47 $\pm$ 4.89	17.19 $\pm$ 7.61	10.70 $\pm$ 4.16	13.46 $\pm$ 6.12

457

458

459

460 Fig.S1 illustrates the relationship between ozone concentration and carbonyl  
461 compounds concentration at each site during the observation period. It is evident that  
462 the spatial distribution of carbonyl compound concentrations is similar to that of ozone  
463 concentration. Regions with severe ozone pollution tend to exhibit higher  
464 concentrations of carbonyl compounds. The variation in carbonyl compound  
465 concentrations is primarily attributed to anthropogenic emissions and prevailing  
466 summer wind directions in the CPUA. Chengdu is the most economically developed  
467 city in the CPUA, with notably higher GDP and industrial production values than other  
468 regions. Chengdu's major industries include coal-fired power plants, chemical plants,  
469 metallurgy and building materials plants, and high concentrations of carbonyls were  
470 observed in here. The unique basin climate of the CPUA, characterized by intense  
471 sunlight and stable atmospheric conditions, facilitates the accumulation of pollutants.  
472 Large amount of industrial emissions and strong photochemical reaction contributes to  
473 ozone pollution. Additionally, during the summer, prevailing northerly winds in the  
474 CPUA facilitate the downwind transport of pollutants from upwind sources, leading to  
475 regional pollution. It is noteworthy that the concentration of carbonyl compounds at the  
476 MY site significantly exceeds that at the CDHKY site. Mianyang, with its industrial  
477 roots, consistently maintains its position as the second-highest GDP contributor in  
478 Sichuan Province. The electronics information industry stands as Mianyang's primary  
479 economic driver, constituting approximately half of the city's total output value. Studies  
480 investigating the volatile organic compound (VOC) source profile in Chengdu(Zhou et  
481 al., 2021) reveal that ethanol and carbonyls predominantly characterize electronics  
482 manufacturing emissions.

### 483 3.2.2 Compositional characteristics

484 According to the composition characteristics of 15 carbonyl compounds in the  
485 ambient air of each city during the observation period (Table S4) . Formaldehyde was

486 the most abundant carbonyl found in these sites followed by acetone and acetaldehyde,  
487 which is widely observed in previous studies. The measured ratios of formaldehyde,  
488 acetone, and acetaldehyde across different sites ranged from 36.4% to 59.4% (average  
489 48.1%), 12.4% to 28.1% (average 19.9%), and 8.2% to 47.3% (average 17.5%),  
490 respectively. In this study, the total measured of formaldehyde, acetaldehyde, and  
491 acetone (FAT) account for over 78% of the total carbonyls concentrations. At the MY  
492 and ZY sites, this proportion even exceeded 90%. It is noteworthy that isobutyraldehyde  
493 (MACR) ranks fourth in the volume concentration of 15 carbonyls measured in the  
494 ambient air surrounding XJ, accounting for 5.3%. MACR, a characteristic product of  
495 isoprene photooxidation from biogenic sources, possibly originates from the abundant  
496 vegetation surrounding XJ. It reflects the period's relatively active photochemical  
497 reactions, with substantial contributions from secondary formation to the measured  
498 carbonyls composition.

499 The observed levels of FAT in different areas were influenced by various factors  
500 including sampling period, geographic location, meteorological conditions, chemical  
501 removal, and source emissions(Z. Zhang et al., 2016). Despite these influences,  
502 comparisons remain valuable in providing an overview of ambient carbonyl levels in  
503 the CPUA. During the summer of 2010, a national wide survey of ambient  
504 monocarbonyl compounds were conducted simultaneously in nine sites (Ho et al.,  
505 2015)found that the total FAT concentration was highest in Chengdu (14.96 ppb),  
506 followed by Beijing (11.83 ppb), and Wuhan (11.70 ppb). Beijing, as the capital of  
507 China, and Wuhan, being one of the top ten most populous cities in China, played  
508 significant roles in this comparison. In our study, the CDHKY site within CPUA  
509 exhibited the highest FAT concentration, with values of 18.25 ppb, surpassing those  
510 recorded in 2010. Furthermore, the total FAT concentrations observed at the CPUA and  
511 XJ sites, with values of 14.99 ppb and 14.90 ppb respectively in our study, closely  
512 resemble those reported in August 2010 in Chengdu. The consistently high levels of  
513 carbonyl compounds observed in Chengdu, both in 2010 and our current study, indicate

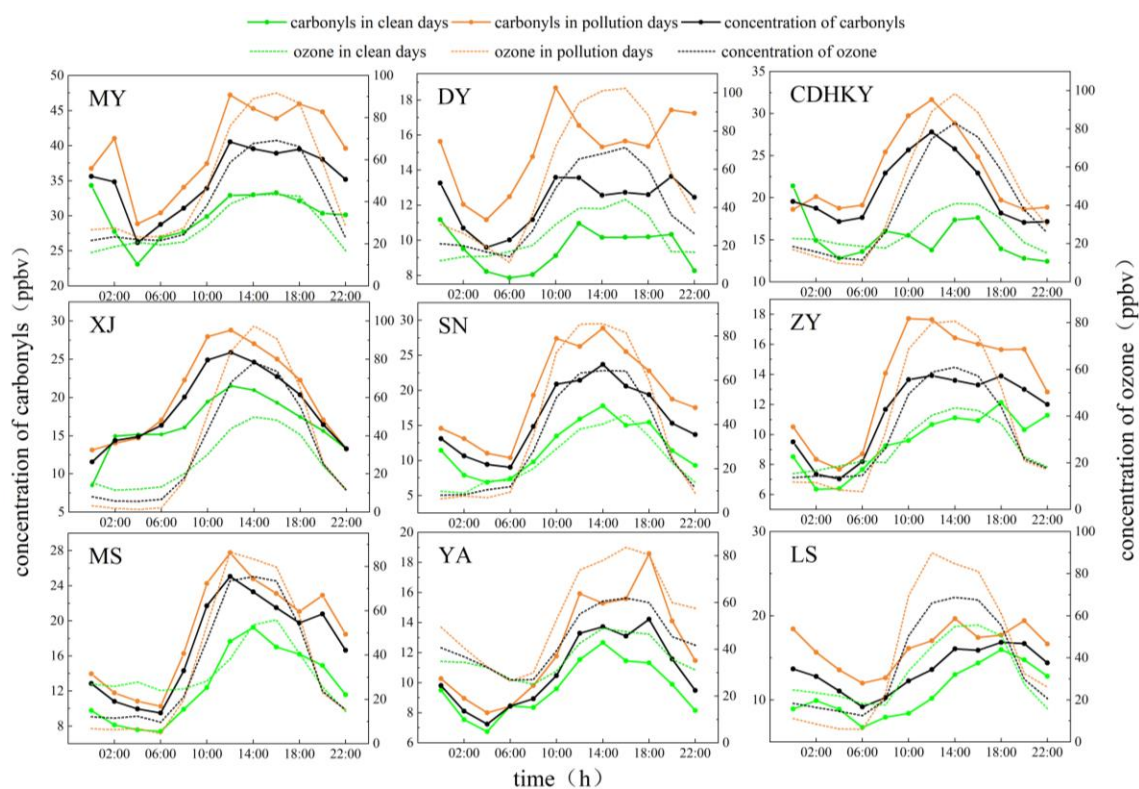

514 that the city likely experiences higher concentrations of these pollutants compared to  
515 other regions across the country. However, more extensive temporal data would be  
516 beneficial to fully validate this pattern at a national scale. Comparing our findings to  
517 international studies, the FAT concentrations at the CDHKY site were lower than those  
518 reported in Rio De Janeiro, Brazil(da Silva et al., 2016), during July to October 2013  
519 (35.43 ppb), but higher than those in Bangkok, Thailand(Kanjanasiranont et al., 2016b),  
520 Orleans, France(Jiang et al., 2016), and the United States(Murillo et al., 2012), with  
521 values of 9.05 ppb, 6.12 ppb, and 5.76 ppb, respectively.

### 522 3.3 Temporal variations of carbonyl compounds

523 The diurnal variation of the total mixing ratio of ambient carbonyl compounds and  
524 ozone concentration around each site in the CPUA during the observation period is  
525 shown in Fig. 4. According to the observation results, the diurnal trend of ozone  
526 concentration at each site showed a "unimodal" variation characteristic, that was, it  
527 gradually increased from the morning to the peak of one day at noon, and then decreased.  
528 The diurnal variation of the total mixing ratio of carbonyl compounds at each site  
529 generally showed a characteristic of high during the daytime and low at night. The  
530 concentration of carbonyl compounds during the day (6:00-16:00) was 48.8% higher  
531 than that at night (18:00-4:00) at the XJ site. This indicated that the concentration of  
532 carbonyl compounds increased by photochemical production during the daytime.  
533 Additionally, deposition processes, particularly dry deposition at night, likely  
534 contribute to the observed diurnal variation in carbonyl levels. The diurnal variation  
535 characteristics of each site were different. For example, the diurnal variation  
536 characteristics of carbonyl compounds concentration at CDHKY, XJ and SN sites were  
537 consistent with those of ozone. The diurnal variation of carbonyl compounds  
538 concentrations at other sites showed "double peaks", peaking at 10:00-12:00 and 18:00-  
539 20:00, respectively. The concentrations of carbonyl compounds at night were also  
540 higher at MY, DY and LS sites. The diurnal minimum values of the total concentration  
541 of carbonyl compounds and ozone concentration appeared at similar time, usually at

542 4:00 a.m. or 6:00 a.m. The first peak of the total mixing ratio of carbonyl compounds  
 543 occurred earlier than the maximum ozone concentration of the day. The first peak of  
 544 the total mixing ratio of carbonyl compounds mostly occurred between 10:00 and 12:00.  
 545 And the maximum ozone concentration mostly occurs between 14:00 and 16:00. This  
 546 was related to the fact that carbonyl compounds were important precursors of ozone.

547 In general, the diurnal variation of the total concentration of carbonyl  
 548 compounds on pollution days and clean days was high during the daytime and low at  
 549 night. The total mixing ratio of carbonyl compounds on pollution days was 22.8%-  
 550 66.2% higher than that on clean days. At the same time, the increase of concentration  
 551 of carbonyl compounds during the daytime on pollution days was higher than that on  
 552 clean days. This suggested that the increase in the concentration of carbonyl  
 553 compounds during the daytime contributed to ozone pollution.

554  
 555 **Figure 4.** Diurnal variations of carbonyl compounds and ozone concentrations at each site in the  
 556 CPUA during the observation period

### 557 3.4 Atmospheric photochemical reactivity of carbonyl compounds

558 During the observation period, the total OH radical consumption rate ( $L_{OH}$ ) and

559 total ozone formation potential (OFP) of the 15 carbonyl compounds at each site are  
 560 depicted in Fig.5. The ranking of total  $L_{OH}$  and total OFP at each site is consistent,  
 561 except for the YA and ZY sites with lower concentrations of carbonyl compounds,  
 562 where the atmospheric photochemical reactivity ranking also aligns with the  
 563 concentration. Among all sites, the MY and CD sites display the highest reactivity,  
 564 while the YA and ZY sites exhibit the lowest reactivity. During the observation period,  
 565 carbonyl compounds significantly contributed to ozone formation. The contributions to  
 566 total VOCs (alkanes, alkenes, alkynes, aromatics, and carbonyl compounds) OFP at the  
 567 MY, SN, ZY, YA, and LS sites ranged from 19.5% to 48.6%. Formaldehyde and  
 568 acetaldehyde were identified as the most reactive species in the atmosphere, surpassing  
 569 other carbonyl compounds in reactivity due to their higher concentrations and inherent  
 570 reactivity, especially formaldehyde. However, acetone exhibited high inertness and a  
 571 prolonged atmospheric lifetime, leading to its accumulation in ambient air with  
 572 concentrations higher than other carbonyl compounds except for formaldehyde and  
 573 acetaldehyde. Thus, despite its elevated concentration, acetone's reactivity remained  
 574 relatively low.

575

576 **Figure 5.**  $L_{OH}$  and OFP of carbonyl compounds at each site in the CPUA during the observation

577

period

### 578 3.5 Sensitivity analysis of ozone formation based on formaldehyde to NO<sub>2</sub> ratio (FNR)

579 The change of O<sub>3</sub> formation sensitivity of each site in the CPUTA during the  
580 observation period is shown in Fig.6. As can be seen from the Fig. 6, most sites remain  
581 in the VOCs-limited regime during the cleaning period and EP1 to EP3. Economically  
582 developed city such as Chengdu, Meishan, with high levels of formaldehyde and NO<sub>2</sub>,  
583 remain in the VOCs-limited regime. Ya'an as a city with the lowest GDP ranking in the  
584 CPUTA, with low levels of formaldehyde and NO<sub>2</sub>, remain in the transitional regime.

585

586 **Figure 6.** The change of O<sub>3</sub> formation sensitivity of each site in the CPUTA during the observation  
587 period. The arrows represent time step from clean period to EP1 to EP2 to EP3.

588 The daily variation of O<sub>3</sub> formation sensitivity and ozone concentration at each  
589 site in the CPUTA during the observation period is shown in Fig. S4. The mean FNR of  
590 each site ranged from 0.48 to 1.29 during the observation period. The FNRs were lower  
591 than 0.55±0.16 at XJ, DY, ZY, CDHKY, and MS, and higher than 1.0 at LS, SN, YA  
592 and MY. At the same time, the mean ozone concentration at each site was between 138  
593 and 192 μg·m<sup>-3</sup>. The mean ozone concentration in XJ, DY, CDHKY and MS was 166-  
594 192 μg·m<sup>-3</sup>, it was 150-164 μg·m<sup>-3</sup> in LS, SN, YA and MY. Therefore, it could be seen  
595 that most of the sites with high mean ozone concentrations during the observation

596 period, like CDHKY, XJ, MS and Deyan sites, were in the VOCs-limited regime, and  
597 most of the stations with low mean ozone concentrations during the observation period  
598 such as YA, SN, MY and LS were in the transitional regime. It was worth noting that  
599 the mean ozone concentration at ZY site (only  $138 \mu\text{g}\cdot\text{m}^{-3}$ ) during the observation  
600 period was much lower than that of other sites, but most of the ZY site was in VOCs-  
601 limited regime, which was mainly related to the low concentration of formaldehyde. In  
602 addition, the FNR value of the MY site was also relatively high, which was mainly  
603 caused by the high concentration of formaldehyde.

604 Based on the ratio of formaldehyde to  $\text{NO}_2$  mixing ratio, most sites remain in the  
605 VOCs-limited regime during the observation period. And the sites with heavy ozone  
606 pollution were in the VOCs-limited regime, and the sites with light ozone pollution  
607 were in the transitional regime. Photochemical reactivity ( $L_{\text{OH}}$  and OFP) analysis  
608 showed that formaldehyde and acetaldehyde contributed significantly to the  
609 enhancement of atmospheric oxidation and ozone formation potential. Therefore, when  
610 heavy ozone pollution occurs in the CPUA, special attention should be paid to the  
611 control of VOCs, especially formaldehyde and acetaldehyde in carbonyl compounds,  
612 under the coordinated control of  $\text{NO}_x$  and VOCs. Overall, this study reveals the  
613 important contribution of carbonyl compounds to ozone pollution in the CPUA, and  
614 provides scientific support for the establishment of ozone pollution prevention and  
615 control measures.

## 616 3.6 Source Analysis of carbonyl compounds

### 617 3.6.1 Quantitative source analysis of key carbonyl compounds

618 The table S7 provides a summary of the background and primary emissions  
619 concentrations of formaldehyde, acetaldehyde, and acetone at nine sites across the eight  
620 cities of the CPUA, along with the proportion of secondary formation contributing to  
621 their concentrations. Background concentrations and primary emissions of  
622 formaldehyde, acetaldehyde, and acetone ranged from 50% to 80%, 46% to 83%, and

623 45% to 78%, respectively. Secondary formation accounted for 20% to 50%, 17% to  
 624 54%, and 22% to 55% of their concentrations, respectively. Notably, in SN and YA, the  
 625 secondary formation of formaldehyde contributed half of the observed concentration,  
 626 indicating it as the predominant source, while acetaldehyde's secondary formation also  
 627 prevailed in these sites. Conversely, acetone, with lower reactivity, primarily originated  
 628 from background concentrations and primary emissions at other sites except YA.  
 629 Moreover, background concentrations and primary emissions were identified as the  
 630 main contributors to carbonyl compounds in XJ and LS.

631 Fig.7 illustrates the secondary formation concentrations of formaldehyde,  
 632 acetaldehyde, and acetone at each site in the CPUA under both clean and polluted  
 633 conditions. Under polluted conditions, the secondary concentrations of formaldehyde,  
 634 acetaldehyde, and acetone exceeded those in clean conditions by 52.4%, 80.3%, and  
 635 58.5%, respectively. The most significant increases in secondary concentrations were  
 636 observed at the SN site, while relatively smaller increases were observed at LS and XJ.

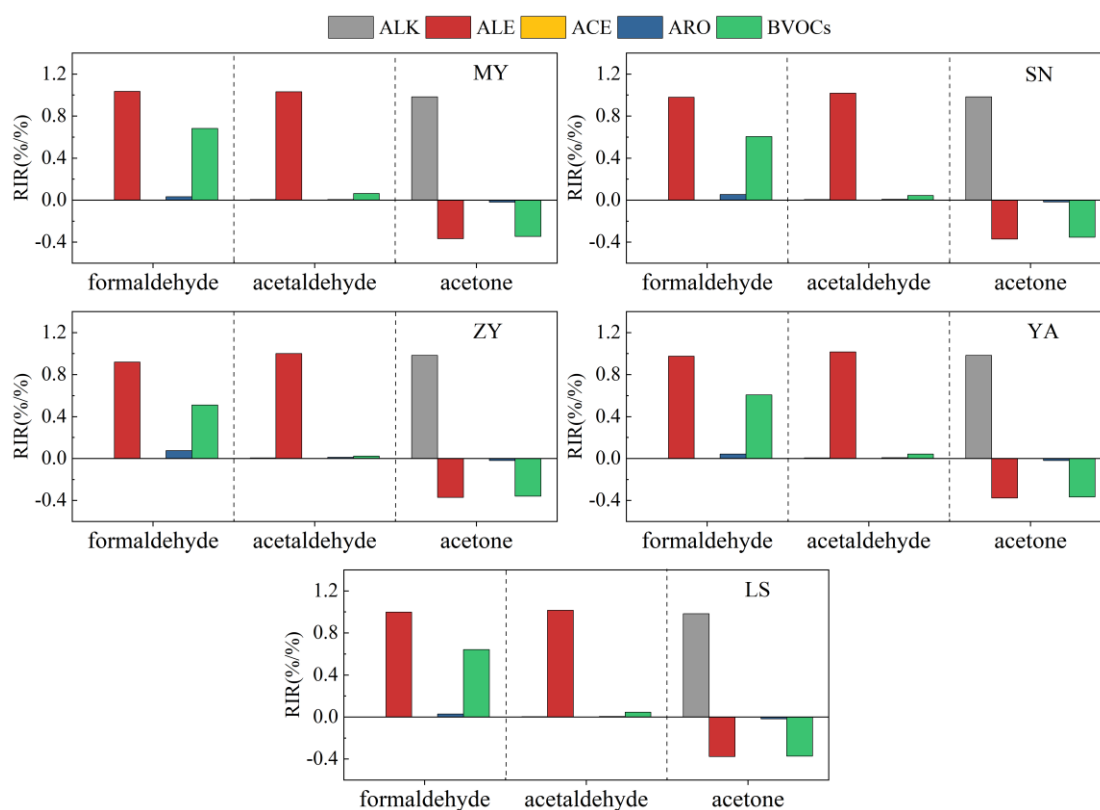

637  
 638 **Figure 7.** Concentrations of formaldehyde, acetaldehyde and acetone in secondary formation  
 639 under different pollution conditions at each site in the CPUA during the observation period

### 640 3.6.2 Exploration of secondary formation mechanism of key carbonyl compounds

641 In this study, we utilized VOC data collected on August 11, 12, and 16, when all  
 642 eight cities in the CPUA were experiencing mild to severe ozone pollution. We  
 643 calculated the Relative Incremental Reactivity (RIR) of formaldehyde, acetaldehyde,

644 and acetone at the MY, SN, ZY, YA, and LS sites on these days. The OBM analysis  
 645 allowed us to assess the impact of anthropogenic VOCs (alkanes, alkenes, alkynes,  
 646 aromatics) and biogenic VOCs (e.g., isoprene) on carbonyl compound formation in the  
 647 context of regional ozone pollution events (Fig.8). Overall, the sensitivities of different  
 648 anthropogenic source and plant source VOCs to formaldehyde, acetaldehyde and  
 649 acetone was consistent among sites. For formaldehyde, reducing alkenes in  
 650 anthropogenic source VOCs and plant VOCs was the most effective way to control  
 651 formaldehyde concentration, while reducing alkenes in anthropogenic source VOCs  
 652 was also beneficial to reduce the formation of acetaldehyde. For acetone with low  
 653 reactivity, the alkanes in anthropogenic source VOCs were the most sensitive to the  
 654 formation of acetone, followed by alkenes and BVOCs. Only the RIR value of alkanes  
 655 were greater than zero, and the RIR values of both alkenes and BVOCs were less than  
 656 zero, indicating that reducing alkanes could reduce the formation of acetone, while  
 657 reducing alkenes and BVOCs was not conducive to acetone concentration control.

658

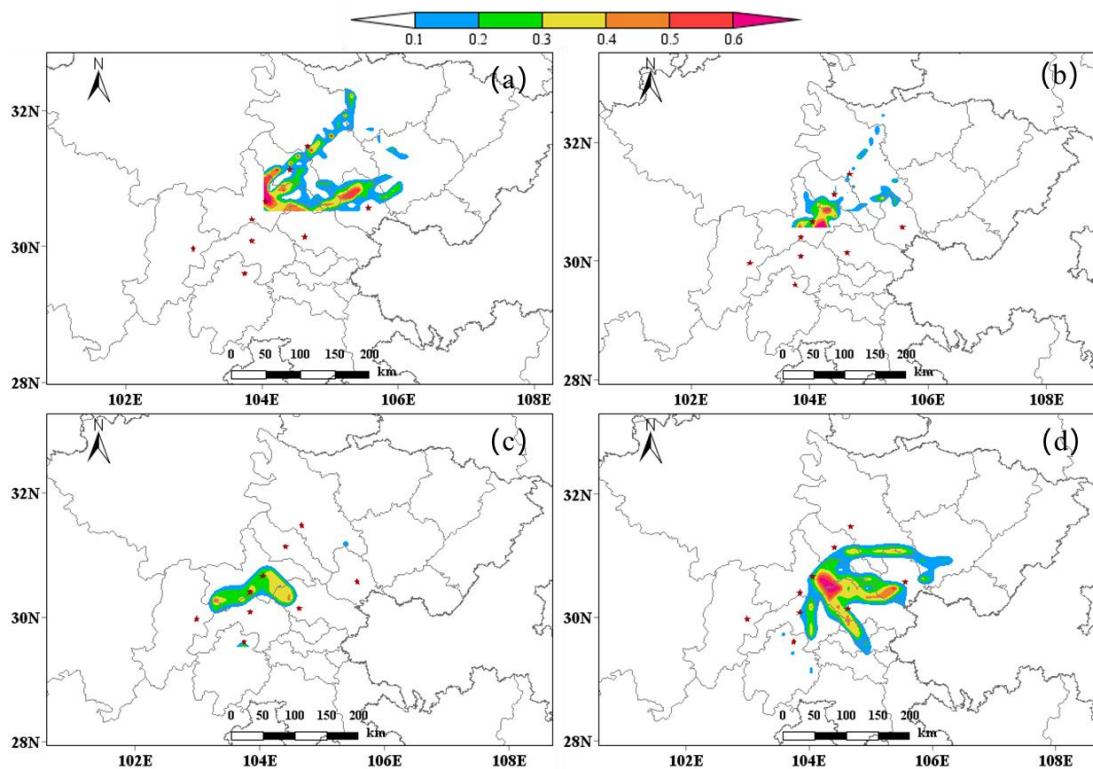

659 **Figure 8.** Mean RIRs of formaldehyde, acetaldehyde and acetone to different anthropogenic

660 source VOCs and biogenic source VOCs at MY, SN, ZY, YA and LS sites on August 11<sup>th</sup>, 12<sup>th</sup> and

### 662 3.6.3 Influence of regional transportation contribution

663 The TrajStat trajectory model was used to calculate and cluster the 24-hour  
664 backward trajectories of air quality at the sampling sites. The backward trajectory  
665 during sampling is shown in Fig.S5. During the observation period, the pollution of  
666 carbonyl compounds in the cities of the CPUA was affected by the mutual transport  
667 among cities in Sichuan Province, especially along the MY-DY-CDHKY route. In  
668 addition, the surrounding provinces and cities of Sichuan Province (Gansu and  
669 Chongqing) also contributed to the carbonyl compounds of the CPUA.

670 The potential sources of carbonyl compounds at different pollution stages at the  
671 CDHKY during the observation period are shown in Fig. 9. It can be seen from the  
672 figure that there are differences in the potential sources of carbonyl compounds among  
673 different pollution stages at the CDHKY site. The concentration of local carbonyl  
674 compounds in CDHKY was high during the early observation period and EP1, which  
675 existed local sources, and was also affected by the northern airflow, and carbonyl  
676 compounds was also affected by the transport from MY, DY and other northern regions.  
677 Under the effect of the continuous northern airflow, the local source emissions  
678 decreased during EP1, and the potential source of carbonyl compounds changed to from  
679 the junction between CDHKY and ZY. During EP3, under the combined influence of  
680 the western airflow, the contribution of transport from SN and ZY to carbonyl  
681 compounds increased, while emissions from local sources also increased.

682

683 **Figure 9.** Analysis of potential sources of carbonyl compounds at different periods at the CDHKY

684 site during the observation period (a) August 4<sup>th</sup>-6<sup>th</sup> (b) August 7<sup>th</sup>-9<sup>th</sup> (c) August 10<sup>th</sup>-13<sup>th</sup> (d)

August 15<sup>th</sup>-18<sup>th</sup>

#### 686 4. Conclusions

687 During a concurrent atmospheric observation campaign conducted at nine sites in  
 688 the CPUA from August 4<sup>th</sup> to 18<sup>th</sup>, 2019, three regional heavy ozone pollution episodes,  
 689 labeled EP1 to EP3, were observed. This study extensively examines the concentration  
 690 variations, atmospheric chemical reactivity, and sources of carbonyls during this period.  
 691 The average total concentrations of 15 carbonyl compounds across the nine sites within  
 692 eight cities of the CPUA were measured at  $17.35 \pm 5.31$  ppb. Spatial analysis revealed  
 693 a positive correlation between carbonyl levels and ozone concentrations, particularly  
 694 concentrated around Chengdu in both northern and southern directions. Formaldehyde  
 695 (36.4%-64.3%), acetone (12.4%-28.1%), and acetaldehyde (8.2%-47.3%) constituted  
 696 the predominant species by volume concentration. Intriguingly, Chengdu exhibited FAT  
 697 concentrations surpassing national and international levels, indicating heightened levels

698 compared to other regions. Diurnal variations showed peaks during the day and lows at  
699 night, with notable spikes on ozone pollution days. A distinctive "weekend effect" was  
700 observed, particularly evident in carbonyl compounds associated with motor vehicle  
701 emissions, such as acetaldehyde and acetone, peaking during morning rush hours and  
702 nighttime on weekends. This suggests significant contributions from both daytime  
703 photochemical processes and nighttime vehicular emissions to carbonyl compounds. At  
704 the MY site, 48.6% of the total volatile organic compounds (VOCs) ozone formation  
705 potential (OFP) was attributed to the 15 carbonyl compounds, emphasizing their  
706 substantial impact on ozone formation, especially formaldehyde and acetaldehyde.

707 Ground-level observations of FNR were utilized to assess the sensitivity of  
708 ground-level ozone formation. FNR from ground-level observations were used to  
709 determine the sensitivity of ground-level ozone formation. Analysis of FNR revealed  
710 that sites experiencing heavy ozone pollution exhibited lower FNRs, indicating a  
711 VOCs-limited regime, while sites with lighter ozone pollution were categorized into a  
712 transitional regime. Carbonyl compound sources include primary emissions and  
713 secondary formation processes. Multivariate linear regression quantitatively analyzed  
714 formaldehyde, acetaldehyde, and acetone sources. Secondary formation contributed  
715 over 30% on average to formaldehyde, acetaldehyde, and acetone, despite primary  
716 emissions being primary sources. OBM modeling revealed that formaldehyde and  
717 acetaldehyde primarily originated from the secondary formation of alkenes and BVOCs,  
718 while acetone mainly stemmed from the secondary formation of alkanes. Furthermore,  
719 it is recommended to establish a scientific control mechanism for both NO<sub>x</sub> and VOCs,  
720 with special attention to formaldehyde, acetaldehyde, and acetone, and their alkenes  
721 precursors. Additionally, considering the regional nature of pollution, this study  
722 suggests that carbonyl compound pollution is influenced by mutual transport among  
723 cities within the CPUA, notably along the MY-DY-CDHKY route. Establishing a  
724 collaborative prevention and control mechanism among cities within the CPUA and  
725 neighboring provinces and cities is crucial to effectively address carbonyl compounds

726 and ozone pollution in the region in the future.

727

728 **Data availability.** Observational data including meteorological parameters and air  
729 pollutants used in this study are available from the corresponding authors upon request  
730 (lihong@craes.org.cn).

731

732 **Author contributions.** Hong Li and Jiemeng Bao designed this study. Xin Zhang,  
733 Zhenhai Wu, Jiemeng Bao, Li Zhou, Qinwen Tan, and Fumo Yang coordinated the  
734 selection of field observation sites, including locations for both VOCs and carbonyls  
735 grid sampling. Qinwen Tan and Hefan Liu supported the collection of carbonyls at one  
736 site. Zhenhai Wu and Xin Zhang assisted in carbonyls sampling; Xin Zhang and  
737 Yunfeng Li assisted in carbonyls sample analysis and data collection. Li Zhou and  
738 Hefan Liu organized the analysis of VOCs measurements. Jun Qian, Junhui Chen, and  
739 Liqun Deng provided support in project funding application. Jiemeng Bao performed  
740 the data analysis and wrote the paper with contributions from all co-authors; Hong Li  
741 reviewed the paper, provided comments and finalized it.

742

743 **Competing interests.** The contact author has declared that none of the authors has any  
744 competing interests.

745

746 **Acknowledgments.** The authors would like to express their sincere appreciation to  
747 Keding Lu and Xin Li of Peking University for their organization of the intensive field  
748 observation experiment on the formation mechanisms of photochemical pollution in  
749 summer in the CPUA of China. They also want to show their deep gratitude to Yulei  
750 Ma, Tianli Song, Xiaodong Wu, Ning Wang, and He Zijun Liu of Sichuan University,  
751 as well as Xin Zhang (female) and Hefan Liu of Chengdu Academy of Environmental  
752 Protection Sciences for their help in sampling. They are also grateful to Liping Liu of  
753 Sichuan Agricultural University in Ya'an City, Kaiyao Lv of Mianyang High-tech Zone

754 Management Committee, Yong Xiao of Deyang Municipal Education Bureau, Ying Ni  
755 of Meishan Ecological Environment Bureau, Aihua Zou of Leshan Ecological  
756 Environment Bureau, and Chuhan Wang of the Chinese Academy of Environmental  
757 Sciences for their substantial support during field observations. Special thanks to Zhen  
758 He and Manfei Yin of the Chinese Academy of Environmental Sciences for their  
759 assistance in analyzing samples from the XJ site.

760

761 **Financial support.** This research has been supported by the Research Project on  
762 Analysis of Multiple Causes of Atmospheric Ozone Pollution in Urban Agglomerations  
763 of Chengdu Plain and Development of Management, Prevention, and Control System  
764 of Sichuan Academy of Environmental Sciences (No. 510201201905430).
