18 **Abstract.** Gaseous carbonyl compounds serve as crucial precursors and intermediates
19 in atmospheric photochemical reactions, significantly contributing to ambient ozone
20 formation. To determine whether the impact of carbonyl compounds on regional ozone
21 pollution is driven by their abundance or by specific secondary chemical processes,
22 simultaneous field observations and observation-based modelling of ambient carbonyls
23 were conducted at nine sites within the Chengdu Plain Urban Agglomeration (CPUA),
24 China during August 4-18, 2019, when three episodes of regional heavy ozone pollution
25 occurred across eight cities within CPUA. Throughout the study, the total mixing ratios
26 of 15 carbonyls ranged from 10.7 ± 4.2 to 35.2 ± 13.4 ppbv. The spatial distribution reveal
27 that regions with higher concentrations of carbonyl compounds, such as around
28 Chengdu, are also areas with more severe ozone pollution. Both the abundance and the
29 chemical reactivity of carbonyl compounds, especially formaldehyde and acetaldehyde,

30 play crucial roles in ozone formation in the CPUA. On ozone pollution days, carbonyl
31 concentrations significantly increased by 22.8% to 66.2%. While the abundance of
32 carbonyls is an important factor, their significant role in heavy ozone pollution within
33 the CPUA is primarily driven by secondary chemical processes, particularly those
34 involving alkenes and BVOCs. Sites with higher average ozone concentrations during
35 observations were mainly in the VOCs-limited regime, while others were in the
36 transitional regime. Additionally, the mutual transport of carbonyl compounds between
37 cities in the CPUA suggests that regional collaboration is essential to address ozone
38 pollution effectively. These findings offer valuable insights for developing effective
39 strategies to control regional ozone pollution.

43 1. Introduction

44 Atmospheric carbonyl compounds play a pivotal role in tropospheric chemistry,
45 acting as crucial precursors to both ozone (O_3) and secondary organic aerosols (SOA),
46 a fact recognized for decades (Altshuller, 1993; Grosjean and Seinfeld, 1989). Their
47 importance has been confirmed by numerous studies over the years (Guo et al., 2004;
48 Hallquist et al., 2009; Wang et al., 2020; Ye et al., 2021; Coggon et al., 2019),
49 highlighting their significant contribution to atmospheric photochemistry and air
50 pollution. Over the past two decades, severe air pollution in China has driven substantial
51 research efforts to understand the contributions of carbonyl compounds to these
52 environmental challenges. Studies have shown that photolysis of carbonyl compounds
53 is a major source of RO_X radicals (Grosjean and Seinfeld, 1989; Zhang et al., 2016).
54 These compounds can be photolyzed and react with OH radicals to form a large number
55 of HO_2 and RO_2 radicals, which increase the atmospheric oxidation capacity and
56 participate in the NO_x photochemical cycle, leading to ozone formation (Zhang et al.,
57 2016; Meng et al., 2017). Additionally, dialdehydes such as glyoxal and methylglyoxal

58 undergo heterogeneous reactions with aqueous particulate matter, rapidly forming SOA
59 (Lou et al., 2010; Xue et al., 2016; Yuan et al., 2012). Ambient carbonyl compounds
60 not only affect the environment but also pose direct health risks to humans. They can
61 harm ecosystems through deposition and adsorption processes (Yang et al., 2018). They
62 also pose direct health risks to humans, including sensitization, carcinogenesis, and
63 mutagenicity (Fuchs et al., 2017).

64 Recent research has increasingly focused on understanding the spatial and
65 temporal variability of carbonyl compounds in highly polluted regions, particularly in
66 China, where rapid industrialization has led to severe air quality challenges. Xue et al.
67 (2013) and Duan et al. (2012) reported typical ambient concentrations of carbonyl
68 compounds ranging from a few $\mu\text{g}\cdot\text{m}^{-3}$ to tens of $\mu\text{g}\cdot\text{m}^{-3}$ in urban areas, depending on
69 the specific compounds and regions studied. For example, formaldehyde concentrations
70 in highly polluted areas can exceed $10\ \mu\text{g}\cdot\text{m}^{-3}$. Shen et al. (2013) and Fu et al. (2008)
71 observed significant diurnal variation, with higher concentrations of carbonyl
72 compounds during the daytime, particularly in the afternoon, driven by photochemical
73 production. Concentrations can increase by as much as 50-100% during peak sunlight
74 hours compared to nighttime levels. Pang and Mu (2006) and Rao et al. (2016)
75 identified key sources of carbonyl compounds, including vehicular emissions, industrial
76 activities, and secondary formation from VOC oxidation in the atmosphere. In urban
77 environments, vehicular emissions are often a dominant primary source, while
78 secondary formation contributes significantly during daytime due to photochemical
79 processes. The results highlight severe and spatiotemporal variations of carbonyl
80 pollution in China. High levels are found mainly in the North China Plain(NCP), the
81 Yangtze River Delta(YRD), and the Pearl River Delta(PRD)(Duan et al., 2008; Shao et
82 al., 2009; Tan et al., 2018; Wang et al., 2018; Xue et al., 2014, 2013; Yang et al., 2017).
83 Urban areas generally exhibit higher carbonyl levels than suburban and rural areas due
84 to human activities(Xue et al., 2013). Despite the progress made, significant gaps
85 remain in understanding the spatiotemporal distribution and source apportionment of

86 carbonyl compounds, particularly in urban agglomerations. Existing research has
87 primarily focused on urban areas in rapidly developing regions like the NCP, YRD, and
88 PRD. Moreover, studies have often emphasized the overall role of VOCs in ozone
89 pollution, with less attention given to specific carbonyl compounds and their individual
90 contributions to atmospheric oxidation capacity and ozone formation (Meng et al.,
91 2017).

92 Monitoring carbonyl compounds in the atmosphere is challenging due to their
93 typically low concentrations (ppt-ppb levels), necessitating highly sensitive analytical
94 methods. The diversity of carbonyl compounds, including multiple isomers, requires
95 highly selective analytical techniques for differentiation. Current measurement
96 technologies limit our understanding of the spatiotemporal distribution of carbonyl
97 compounds, affecting the accurate assessment of their environmental behavior, sources,
98 and transport (Xue et al., 2013; Sahu and Saxena, 2015). While numerous studies have
99 explored the role of carbonyl compounds in ozone production, many focus on general
100 mechanisms rather than specific compounds or regional variations (Atkinson and Arey,
101 2003; Monks et al., 2015).

102 Atmospheric carbonyl compounds originate from both primary and secondary
103 sources (Pang and Mu, 2006; Rao et al., 2016). Primary sources include the incomplete
104 combustion of fossil fuels and biomass, industrial emissions, emissions from the
105 catering industry, and releases from plants. Secondary sources arise from the
106 atmospheric photochemical oxidation of VOCs (Xue et al., 2013), particularly
107 alkenes, aromatics, and isoprene, which typically dominate the secondary formation of
108 carbonyls. However, distinguishing between primary and secondary contributions
109 remains challenging. Existing source apportionment methods, such as characteristic
110 species ratios and multiple linear regression, often lack the resolution to differentiate
111 these sources accurately, especially for non-vehicular emissions and secondary
112 formation. The limitations of these methods underscore the need for more advanced
113 approaches to better quantify the secondary formation mechanisms of carbonyl

114 compounds and their regional impact on ozone formation. Despite significant
115 advancements in studying atmospheric carbonyls, key gaps remain in understanding
116 their precise spatiotemporal distribution and source apportionment. Specifically, there
117 is a need for studies that examine how carbonyls vary across different environments—
118 urban, suburban, and rural—and during varying pollution events. Without such targeted
119 analysis, our understanding of the behavior of carbonyl compounds and their
120 contribution to ozone pollution remains incomplete, particularly in regions
121 experiencing severe pollution.

122 This study focuses on atmospheric carbonyl compounds and their roles in
123 photochemical pollution within the Chengdu Plain Urban Agglomeration (CPUA) of
124 China. The CPUA includes eight cities: Chengdu, Mianyang, Deyang, Leshan, Meishan,
125 Yaan, Suining, and Ziyang. This region has a developed economy and a high degree of
126 internationalization. The CPUA is located on the western edge of the Sichuan Basin,
127 surrounded by mountain ranges, which easily block airflow. The unique climatic
128 environment of the CPUA features low wind speeds year-round, high frequency of
129 static winds, short hours of sunshine, frequent winter inversions, and a pronounced heat
130 island effect in summer. These climatic characteristics significantly impact the
131 variations in air pollutant concentrations, making the region prone to ozone pollution
132 in summer and haze pollution in winter. (Li et al., 2013; Hu et al., 2017; Zhang et al.,
133 2010). Although previous studies have shown that ozone formation in urban Chengdu
134 is primarily VOCs-limited (Tan et al., 2018), with aromatic hydrocarbons and alkenes
135 contributing significantly to ozone generation in summer (Xu et al., 2020), these studies
136 mainly focus on single cities and overall VOCs. There is still limited understanding of
137 whether the significant roles of carbonyl compounds in ozone formation are primarily
138 due to their abundance or whether specific chemical reactions involving carbonyls drive
139 this process. This study aims to address these gaps by investigating the spatial
140 distribution, sources, and specific chemical pathways of carbonyl compounds across
141 the entire CPUA and assessing their contributions to regional ozone pollution and inter-

142 city air transport mechanisms.

143 To address these research gaps, this study involves an intensive field observation
144 experiment conducted by the Sichuan Academy of Environmental Sciences, Peking
145 University, Sichuan University and Chinese Academy of Environmental Sciences.
146 Atmospheric carbonyl compounds were observed at nine sites in eight cities within the
147 CPUA for 15 days during a period of heavy ozone pollution in August 2019. Samples
148 were analyzed using 2,4-dinitrophenylhydrazine solid phase adsorption/high
149 performance liquid chromatography (HPLC). The study aims to characterize the
150 atmospheric carbonyl compounds in the CPUA, assess their influence on
151 photochemical pollution, identify key carbonyl compounds that may play crucial roles
152 in heavy ozone pollution in the CPUA, and evaluate the contribution of primary
153 emissions, air pollution transport, and secondary generation to key carbonyl compounds
154 through a combination of multivariate linear regression modeling and Observation-
155 Based Modeling (OBM). This research aims to provide technical support for controlling
156 carbonyl compounds pollution in the CPUA and to reduce their contributions to ozone
157 pollution.

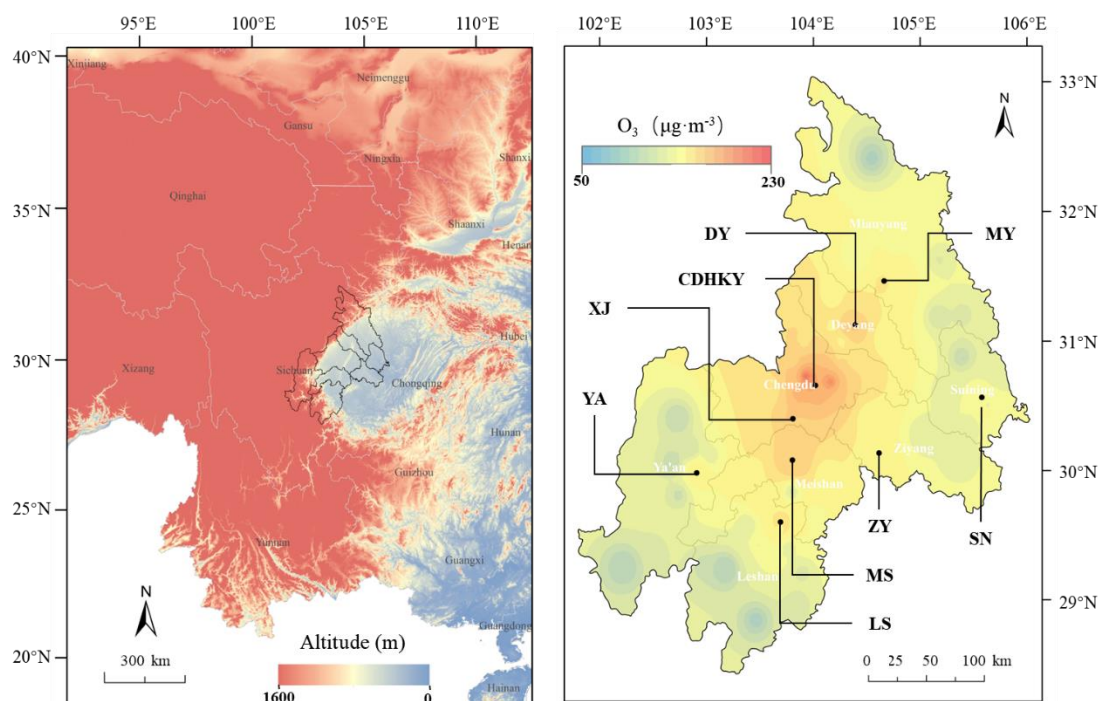

158 **2. Materials and methods**

159 **2.1 Observation Sites Profile**

160 In this study, a total of 9 off-line sampling sites for atmospheric carbonyl
161 compounds were set up in 8 cities in the CPUA from August 4th to 18th, 2019(table S1).
162 Considering that this study focused on the pollution characterization of carbonyl
163 compounds in urban areas, one urban site was selected in each city. In addition, in order
164 to compare and study the pollution characteristics of carbonyl compounds in the
165 suburbs, a suburban site was set up in Xinjin County, Chengdu. For the selection of
166 urban sites in each city, priority is given to those choices of set-up in the vicinity of the
167 state-controlled site, and the perimeter of the sites should be open, unobstructed and no
168 obvious pollution sources, with convenient transportation and power supply. The

169 distribution of specific sites is shown in Fig. 1.

170 Ozone concentrations were measured using the UV absorption method with a
171 Thermo O₃ analyzer (Model 49i), with data sourced from national control stations near
172 each sampling site. Nitrogen dioxide (NO₂) was measured by chemiluminescence
173 following chemical conversion to nitric oxide (NO) using a molybdenum catalyst;
174 however, this method is known to have interferences from other NO_x species. Carbon
175 monoxide (CO) was measured via infrared absorption with a Thermo instrument
176 (Model 20). All Thermo instruments were carefully maintained and calibrated daily at
177 01:00 to ensure measurement accuracy. Measurements for ozone, NO₂, and CO were
178 collected with a time resolution of one hour. Simultaneously, meteorological
179 parameters—temperature, relative humidity (RH), wind speed, and direction—were
180 recorded at each observation site using an automatic weather station (PC-4, JZYG,
181 China), also at a one-hour resolution.

182
183 **Figure 1.** Distribution of sampling sites. The left panel shows the elevation map of the Sichuan
184 Basin, highlighting the geographical features of the region, with elevation data sourced from the
185 Geospatial Data Cloud (<https://www.gscloud.cn/#page1/2>). The right panel presents the spatial
186 distribution of ozone concentrations in the CPUA during the observation period (August 4–18,
187 2019), with ozone data obtained from national control stations near each sampling site. Black dots
188 represent the locations of the sampling sites, labeled as follows: MY (Mianyang), DY (Deyang),

189 CDHKY (Chengdu Environmental Science Research Institute), XJ (Xinjin), SN (Suining), ZY
190 (Ziyang), MS (Meishan), YA (Ya'an), and LS (Leshan). The color bar in the top left corner
191 corresponds to interpolated ozone concentrations, with each color representing a concentration
192 gradient.

193 2.2 Samples Collection

194 The sampling of atmospheric carbonyl compounds mainly referred to the TO-11A
195 standard of the United States Environmental Protection Agency (US EPA) and the
196 Chinese environmental protection standard HJ 683-2014 High Performance Liquid
197 Chromatography Method for the Determination of Atmospheric Carbonyl Compounds,
198 and the sampling was carried out by using silica gel sampling tubes (IC-DN3501 from
199 Tianjin Bonna-Agela) coated with DNPH (2,4-dinitrophenylhydrazine). In this study,
200 an automatic sampler for carbonyl compounds (Zhang et al., 2019) was used to
201 continuously collect atmospheric carbonyl compounds. From August 4th to 18th, 2019,
202 air samples were collected every 2 hours with a sampling flow rate of 0.8 L·min⁻¹. In
203 addition, in order to prevent the impact of ozone and rainwater in the atmospheric air
204 on sample collection, a potassium iodide ozone removal column (KI 140 from Tianjin
205 Bonna-Agela) was installed and a water removal agent made by ourselves (Bao et al.,
206 2022; Wang et al., 2020) was added at the front end of the sample tube. Two blank
207 samples were collected before and after the sampling, and blank samples were also
208 collected for different batches of sampling tubes. The samples were frozen at -18°C and
209 analyzed within one month.

210 Atmospheric VOCs were sampled using SUMMA tanks, stainless steel tanks with
211 electropolished and silanized inner walls, manufactured by Entech in the United States,
212 with a sampling volume of 3.2 liters. The sampling was controlled by a constant current
213 integral sampler to sampling for an average of 1 hour. From August 4th to 18th, 2019,
214 two VOCs samples were collected each day at each site, at 8:00-9:00 and 14:00-15:00
215 (no samples were taken under special weather conditions, such as rain). On August 11th,
216 12th and 16th, six samples were collected per day to capture diurnal variations under

217 ozone pollution events, at the following times: 8:00-9:00, 10:00-11:00, 12:00-13:00,
218 14:00-15:00, 16:00-17:00, and 18:00-19:00.

219 2.3 Samples Analysis

220 The carbonyl compounds samples were qualitatively and quantitatively analyzed
221 by using High Performance Liquid Chromatography (HPLC) (LC-20AD, Shimadzu,
222 Japan) and an ultraviolet detector (SPD-20A, Shimadzu, Japan), mainly based on the
223 US EPA TO-11A standard and the Chinese HJ 683-2014 standard. The DNPH sampling
224 column after sampling was slowly eluted into a volumetric flask using acetonitrile
225 (chromatographically pure, Thermo Fisher Scientific China) to 5.0 mL. Then 1.5 mL of
226 the sample was transferred into an HPLC sample bottle, and sealed and stored in a
227 refrigerator at $<4\text{ }^{\circ}\text{C}$ to complete the pre-treatment. Prior to sample analysis, a standard
228 solution of the concentration gradient was prepared using TO-11A standard solution
229 (Supelco, USA) and used as the external standard. The correlation coefficient (R^2) of
230 the standard curve was greater than 0.995. The detection limit of the device was
231 $0.56\sim 5.57\text{ ng}\cdot\text{mL}^{-1}$, and the quantification limit was $1.87\sim 18.56\text{ ng}\cdot\text{mL}^{-1}$ (Table S2).
232 Then $20\text{ }\mu\text{L}$ of the pretreated sample was extracted through the autosampler and injected
233 into the HPLC/UV system, detected by a UV detector with a wavelength of 360 nm,
234 qualified by retention time value, quantified by peak area value, and the qualitative and
235 quantitative analysis data of carbonyl compounds were obtained after conversion. The
236 HPLC conditions referred to Chinese environmental protection standard HJ 683-2014:
237 binary gradient washing was performed using acetonitrile and water, 60% acetonitrile
238 was held for 20 mins, acetonitrile was increased linearly from 60% to 100% within 20-
239 30 mins, and acetonitrile was reduced to 60% again within 30-32 mins and held for 8
240 mins; the column oven was kept at $40\text{ }^{\circ}\text{C}$. It should be noted that while the sampling
241 and analysis method was effective for most carbonyl compounds, ketones, including
242 methyl vinyl ketone (MVK), were not well sampled during the field observations. As a
243 result, data for MVK and other ketones were missing. During the observation period,
244 DNPH cartridges and HPLC analysis technique were used to detect a total of 15

245 carbonyl compounds (Table S2).

246 The atmospheric VOCs were analyzed using the TO-14 and TO-15 methods,
247 which are recommended by the US EPA. These methods involve frozen
248 preconcentration coupled with gas chromatography and mass spectrometry (GC-MS).
249 TO-15 is a method for detecting and quantifying a wide range of VOCs from air samples.
250 The VOCs were pre-concentrated by the Entech7100 system at a low temperature, then
251 quantified by an Agilent GC-MS. During the sample analysis, four internal standard
252 gases (bromochloromethane, 1,4-difluorobenzene, chlorobenzene-d5, and 4-
253 bromofluorobenzene) were used. A multi-point calibration curve was created using a
254 standard gas containing 118 VOCs, including PAMS compounds, TO-15 target analytes,
255 and carbonyl compounds. PAMS (Photochemical Assessment Monitoring Stations)
256 compounds are a subset of hydrocarbons known to contribute to ozone formation, such
257 as ethane, ethylene, propane, and others.

258 **2.4 Data Analysis**

259 **2.4.1 Ozone pollution assessment criteria**

260 According to the Technical Regulation on Ambient Air Quality Index (on trial),
261 National Environmental Protection Standard of the People's Republic of China HJ
262 633—2012, days with an ozone pollution index (IAQI) of 100 or higher during the
263 observation period were designated as pollution days, while days with an IAQI below
264 100 were considered clean days. This study compared the pollution characteristics of
265 carbonyl compounds between pollution days and clean days. Additionally, the
266 concentrations of formaldehyde, acetaldehyde, and acetone observed during the
267 summer of 2009-2013 in economically developed and industrialized areas such as
268 Beijing, Shanghai, and Guangzhou in China, as well as locations in South America
269 (Brazil), Asia (Thailand), Europe (France), and North America (United States), were
270 selected and compared.

271 **2.4.2 Ozone formation sensitivity**

272 Previous studies have shown that the formaldehyde to NO₂ ratio (FNR) can be
273 used to determine the sensitivity of O₃-NO_x-VOCs (Schroeder et al., 2017; Tonnesen
274 and Dennis, 2000; Vermeuel et al., 2019). Most studies used satellite remote sensing-
275 based FNR, but the FNR column concentration ratios inverted by satellite remote
276 sensing mainly represented the average photochemical of the troposphere, and the
277 concentration distributions of HCHO and NO₂ in the vertical direction were
278 inconsistent (Hong et al., 2022; Schroeder et al., 2017). So, there is a large uncertainty
279 to develop ground-level ozone pollution prevention and control measures. In this study,
280 sensitivity analysis of ground-level ozone formation was carried out based on the ratio
281 of ground-level HCHO to NO₂ during the observation period at the 9 sites of 8 cities in
282 the CPUA. FNR < 0.55±0.16 and FNR > 1.0±0.3 were defined to VOCs-limited and
283 NO_x-limited, respectively, and FNR ratio ranged from 0.55±0.16 to 1.0±0.3 defined to
284 NO_x and VOCs co-limited (Liu et al., 2021; Zhang et al., 2022).

285 2.4.3 Exploration of Secondary Formation Mechanisms

286 (1) Atmospheric chemical reactivity

287 In this study, the contribution of atmospheric chemical reactivity of carbonyl
288 compounds to ozone formation was evaluated using the OH free radical consumption
289 rate (L_{OH}) and ozone formation potential (OFP):

$$290 L_{OH} = [OVOC]_i \times k_i(OH) \quad (1)$$

291 Where, [OVOC]_i was the observed concentration of the ith (i=1 to n) carbonyl
292 compound, in molecule·cm⁻³; k_i(OH) was the rate constants of the ith carbonyl
293 compound reacting with OH radicals, in cm³·(molecule·s)⁻¹. The unit of L_{OH} is s⁻¹,
294 representing the rate of OH radical consumption. The selected k_i(OH) values were from
295 literature (Atkinson and Arey, 2003).

$$296 OFP = MIR_i \times [OVOC]_i \quad (2)$$

297 Where, MIR was the maximum incremental reactivity of the ith carbonyl
298 compound, in g O₃·(g VOC)⁻¹ (grams of ozone formed per gram of volatile organic

299 compound), and the MIR values of each species were from California Code of
300 Regulations (<https://govt.westlaw.com>); $[\text{OVOC}]_i$ was the mass concentration of the i^{th}
301 carbonyl compound, in $\mu\text{g}\cdot\text{m}^{-3}$. The unit of OFP is $\mu\text{g}\cdot\text{m}^{-3}$, representing the potential
302 ozone formation.

303 (2) Observation-based model (OBM)

304 The Observation-Based Model (OBM) is a box model that uses actual
305 observational data to evaluate the sensitivity of secondary pollutant formation
306 mechanisms to their precursor emissions. By constraining the model with atmospheric
307 observation data, typical secondary pollutants and parameters such as NO_x , SO_2 , CO ,
308 VOCs, temperature, humidity, pressure, and JNO_2 are input into the model as hourly
309 observational data to calculate the chemical formation and consumption of secondary
310 pollutants and free radicals. In this study, the OBM model used the Master Chemical
311 Mechanism (MCM) (v3.3.1, mcm.leeds.ac.uk), which is a nearly detailed chemical
312 mechanism that describes the chemical processes of 143 VOC species from emission
313 to degradation in the atmosphere, including approximately 6,700 species and 17,000
314 inorganic and organic reactions. In this version of the MCM, a total of 19 carbonyl
315 compounds are included, comprising 9 aldehydes and 10 ketones. Of these, 9 carbonyl
316 compounds were measured in this study, including formaldehyde, acetaldehyde,
317 acetone, propionaldehyde, crotonaldehyde, butyraldehyde, isovaleraldehyde,
318 valeraldehyde, and hexaldehyde. The MCM chemical mechanism can simulate
319 atmospheric photochemical reaction processes under near-real conditions and calculate
320 the concentrations of highly reactive species, quantifying the reaction rates of all
321 species involved. For VOCs, especially carbonyls, that were not directly measured, the
322 MCM uses estimated values derived from emission inventories, literature data, and
323 assumptions based on similar species to provide estimates for their concentrations and
324 reaction rates.

325 Relative Incremental Reactivity (RIR) was first used by Cardelino and Chameides

326 (1995) to simulate the response of ozone to precursor changes through scenario tests
 327 using box model calculations. RIR was calculated by assuming that the concentration
 328 of a given carbonyl compound precursor decreased by a certain proportion could cause
 329 the change of the concentration of the carbonyl compound, so as to further judge the
 330 effect of VOCs on the formation of carbonyl compounds. Combining the concentrations
 331 and activity levels of 15 carbonyl compounds during the observation period, this study
 332 focused on formaldehyde, acetaldehyde, and acetone as the primary research targets.
 333 The impacts of various AVOCs (anthropogenic VOCs) ,including alkanes, alkenes,
 334 alkynes, and aromatic hydrocarbons, as well as BVOCs (biogenic VOCs) like isoprene,
 335 on the formation of formaldehyde, acetaldehyde, and acetone were assessed using
 336 observation-based OBM classification. Specific species of anthropogenic source VOCs
 337 (alkanes, alkenes, alkynes, and aromatic hydrocarbons) and biogenic VOCs (isoprene)
 338 are detailed in Table S3.

339 VOCs observations, conventional gases (NO₂, CO and SO₂) and meteorological
 340 parameters (temperature, relative humidity and pressure) were imputed into the model.
 341 It was assumed that the pollutants are well mixed. Under the constraints of the measured
 342 hourly concentration data of pollutants, the atmospheric chemical process was
 343 simulated to obtain the source-effect relationship of the measured pollutants. By
 344 assuming the reduction of the source effect, the RIRs of different carbonyl compounds
 345 precursors were calculated, and the sensitivities of carbonyl compounds to different
 346 pollutants were obtained, and then the secondary formation mechanism of carbonyl
 347 compounds was determined. The formula to calculate the RIR is as follows:

$$348 \quad RIR(X) = \left[\frac{\Delta P_Y(X)/P_Y(X)}{\Delta S(X)/S(X)} \right] \quad (3)$$

$$349 \quad P_Y = Y_{\text{net formation}} - Y_{\text{net consumption}} \quad (4)$$

350 Where X was a specific species; P_Y(X) was the net formation rate of species y;
 351 S(X) was the total amount of emissions of species X in a certain period, i.e., the source
 352 effect of species X. ΔS(X) was the change in total emissions of X caused by the
 353 hypothetical change in source effect, ΔP_Y(X) was the change in P_Y(X) after the change

354 in source effect $S(X)$, and $RIR(X)$ was the relative incremental reactivity of species X.
355 The species Y in this study were formaldehyde, acetaldehyde and acetone, respectively,
356 and pollutant X was reduced by 20%.

357 The absolute RIR of the precursor reflects the sensitivity of carbonyl compounds
358 formation to the precursor. The higher the absolute RIR, the more sensitive the carbonyl
359 compounds formation to the precursor. A positive RIR value indicates that reducing the
360 species can reduce the formation rate of species Y, and a negative RIR value indicates
361 that reducing the species can increase the formation rate of species Y.

362 2.4.4 Sources Analysis

363 (1) Multi-linear regression model

364 There is a good correlation between concentrations of compounds of the same or
365 similar source in the atmosphere. Based on this property, it was assumed that the
366 primary and secondary sources of carbonyl compounds were linearly correlated with
367 the selected tracers, and then a quantitative source model was established by multiple
368 linear statistical regression analysis (Kanjanasiranont et al., 2016a; Li et al., 2010; Ling
369 et al., 2017; Luecken et al., 2012; Lui et al., 2017; Wang et al., 2017). In general, CO is
370 the marker product of typical anthropogenic combustion source emissions, mainly from
371 vehicle exhaust emissions and coal combustion. Ozone, as an indicator of
372 photochemical smog, is a typical secondary formation pollutant. In this study, CO and
373 ozone were selected as the tracers of primary source and secondary source of carbonyl
374 compounds, respectively. The formula is as follows:

$$375 \quad [carbonyl] = \beta_0 + \beta_1[CO] + \beta_2[O_3] \quad (6)$$

376 Where $[carbonyl]$, $[CO]$ and $[O_3]$ represented the observed mixing ratios of
377 carbonyl compounds, CO and ozone, respectively, in ppbv. β_0 , β_1 and β_2 were
378 coefficients obtained by multiple linear regression fitting model, in ppbv/ppbv. β_0
379 represented the background concentration of a given carbonyl compound, β_1
380 represented the emission ratio of the carbonyl compound relative to CO. $\beta_1[CO]$ and

381 $\beta_2[O_3]$ represented the concentrations of carbonyl compound in primary emission and
382 secondary formation, respectively, in ppbv.

383 In addition, the relative contribution of primary emissions, secondary formation
384 and background concentrations of carbonyl compounds can be calculated using the
385 following formula:

$$386 \quad P_{primary} = \frac{\beta_1[CO]_i}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (7)$$

$$387 \quad P_{secondary} = \frac{\beta_2[O_3]_i}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (8)$$

$$388 \quad P_{background} = \frac{\beta_0}{(\beta_0 + \beta_1[CO]_i + \beta_2[O_3]_i)} \times 100\% \quad (9)$$

389 Where, $P_{primary}$ represented the contribution of the primary emission of a given
390 carbonyl compound, %; $P_{secondary}$ represented the contribution of the secondary
391 formation of the carbonyl compound species, %; $P_{background}$ represented the contribution
392 of the carbonyl compounds species from sources other than primary emissions and
393 secondary formation, %.

394 (2) Backward trajectory model

395 The effects of long-distance air mass transport on the pollution of carbonyl
396 compounds in the CPUA were studied using MeteInfo software and TrajStat plug-in
397 (<http://www.meteothink.org/downloads/index.html>) .In this model, meteorological
398 data were relevant meteorological data from the global data assimilation system (GDAS)
399 database (<ftp://arlftp.arlhq.noaa.gov/pub/archives/gdasl>). A trajectory simulation height
400 of 500 m above ground level (AGL) was selected. The duration of backward trajectory
401 was 48 h. The daily start time was 00:00 UTC. The analog frequency was 2 h. The
402 backward trajectory diagram was calculated. Meanwhile, the clustering method in
403 TrajStat software and the Euclidean distance algorithm were used to cluster the airflow
404 trajectory to the CPUA. And then the statistical analysis was carried out in combination
405 with the corresponding pollutant mass concentration characteristics.

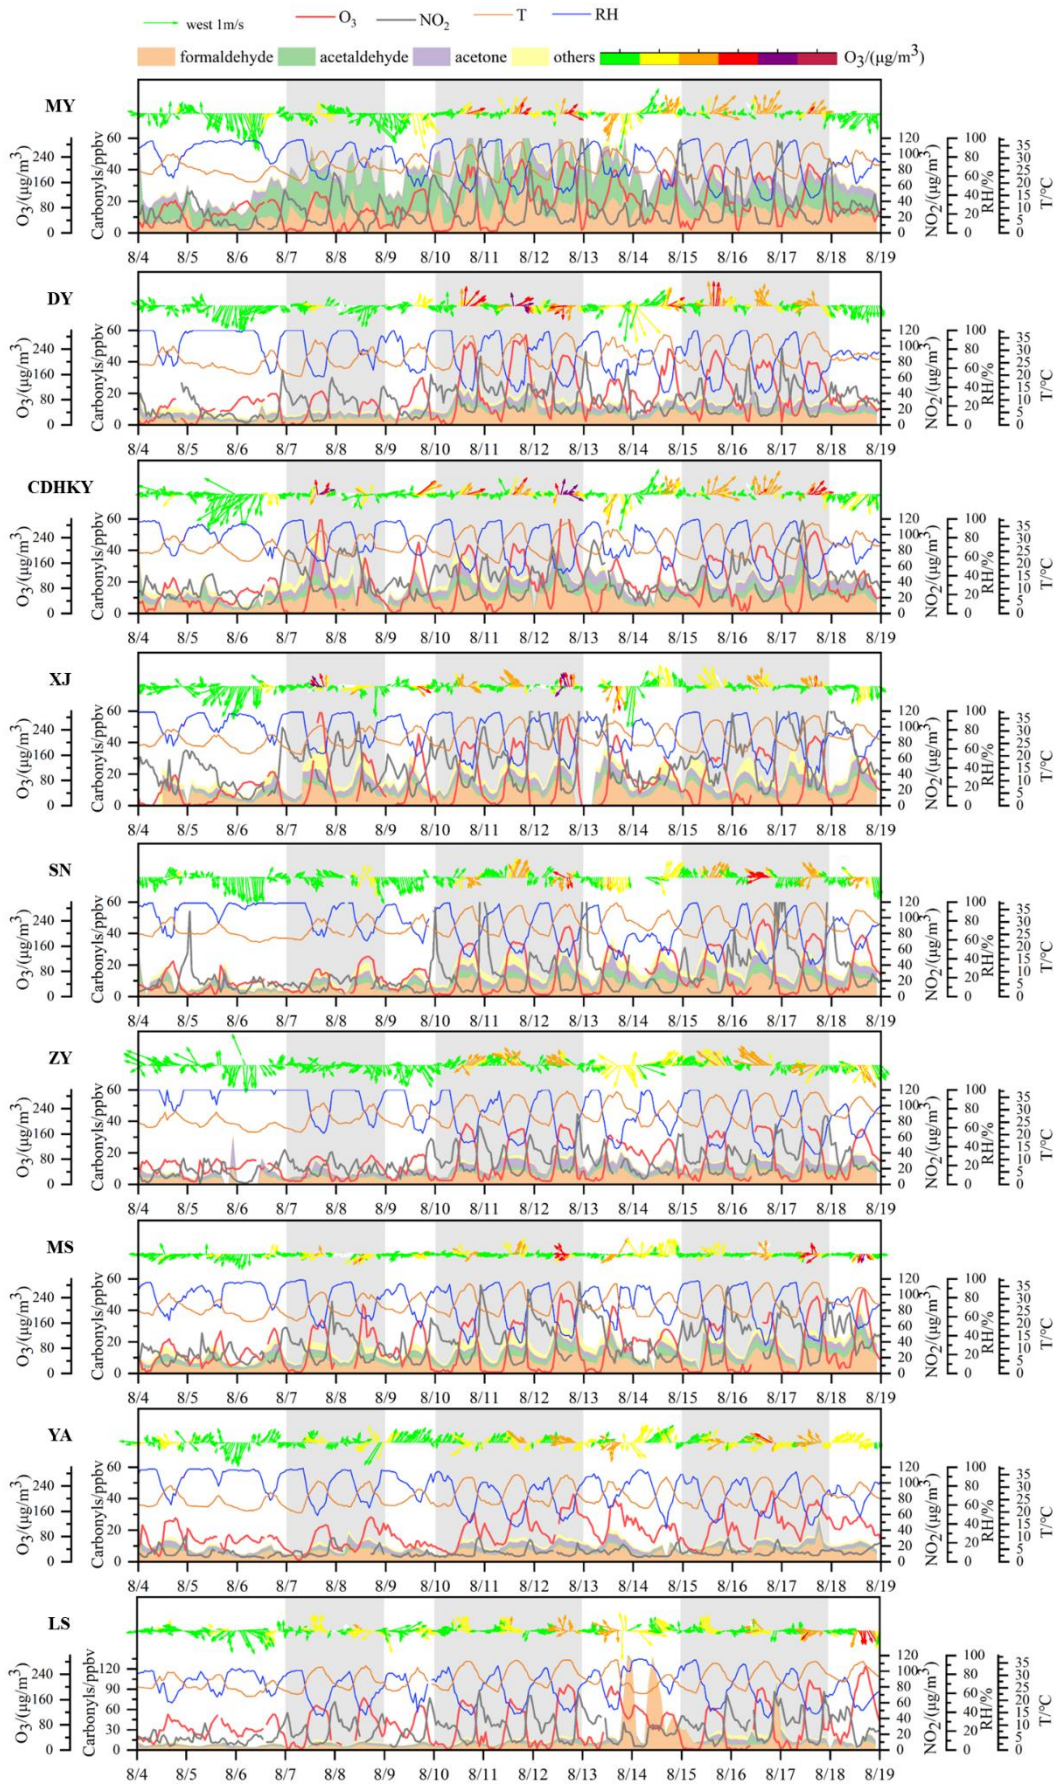

406 3. Results and Discussion

407 3.1 Overview of air quality during observation period

408 Due to the influence of cooling and precipitation caused by cold air intrusion, the
409 early observation period (from August 4th to 6th, 2019) in the Chengdu Plain Urban
410 Agglomeration (CPUA) experienced slightly lower temperatures (25.1°C) and higher
411 humidity (87.6%). These conditions were unfavorable for ozone formation. Although
412 ozone itself is not easily removed by rain, precipitation reduces ozone pollution by
413 washing away its precursors, such as nitrogen oxides (NO_x) and polar volatile organic
414 compounds (VOCs), such as aldehydes, ketones, and others, decreasing sunlight
415 exposure, and enhancing atmospheric dispersion. However, as temperatures increased
416 and humidity dropped in the subsequent days, more favorable conditions for ozone
417 formation emerged, leading to heavy and persistent regional ozone pollution in the
418 CPUA. By August 12th, the mean temperature had gradually increased to 29.1°C, while
419 it averaged 27.7°C from August 13th to 14th. During this time, cumulative precipitation
420 reached 975 mm, resulting in temporary alleviation of ozone pollution. Subsequently,
421 temperatures rose again from August 15th to 18th, with the mean temperature persisting
422 above 28.4°C for several days, accompanied by a decrease in humidity to a minimum
423 of 64.8% on August 17th. Overall, during the observation period (from August 4th, 2019,
424 0:00 to August 18th, 2019, 24:00), three episodes of severe ozone pollution occurred,
425 namely EP1 (August 7th to 9th), EP2 (August 10th to 13th), and EP3 (August 15th to 18th),
426 as depicted in Fig. 2.

427 Fig.3 illustrates the temporal and spatial variations of ozone and NO₂
428 concentrations, as well as temperature and humidity at each site during the observation
429 period. After observing the spatial distribution of ozone concentration during EP1, it's
430 evident that the severity of pollution reached heavily polluted levels, with Chengdu
431 recording an MDA8 concentration of 297 $\mu\text{g}\cdot\text{m}^{-3}$ on August 7th. This distribution
432 demonstrated a radial decrease from Chengdu to the surrounding areas. However, the
433 subsequent episodes, EP2 and EP3, exhibited even broader ranges of ozone pollution
434 and more pronounced spatial movements. During the early stages of EP2 and EP3 (from

435 August 10th to 11th and from August 14th to 15th, respectively), high ozone
436 concentrations were observed in the Chengdu-Deyang-Mianyang region. In the middle
437 stages (August 12th and from August 16th to 17th, respectively), influenced by northerly
438 airflow, regions with high ozone concentrations expanded to the central (Meishan,
439 Ziyang, and Suining) and southwestern (Leshan and Ya'an) parts of the CPUA. In the
440 later stages (August 13th and August 18th), under the influence of northwesterly airflow,
441 regions with high ozone concentrations (Meishan and Leshan) moved southward again,
442 while ozone pollution in other areas of the CPUA gradually weakened. On August 11th
443 to 12th and August 16th to 17th, ozone concentrations in the eight cities of the CPUA
444 reached light pollution levels or higher, with the heaviest pollution recorded on August
445 12th. Specifically, Deyang, Mianyang, Suining, and Meishan reached moderate
446 pollution levels, while Chengdu reached heavy pollution with a concentration of 324
447 $\mu\text{g}\cdot\text{m}^{-3}$.

448

449 **Figure 2.** Overview of air quality at each site during the observation period. The gray shaded parts

450

respectively represent the three heavy ozone pollution episodes (EP1, EP2,EP3).

451

452 **Figure 3.** Temporal and spatial variations of (a) ozone concentration, (b) NO₂ concentration, (c)

453

temperature and (d) humidity in the CUPA during the observation period.

454 3.2 Comparative characterization of carbonyl compounds

455 3.2.1 Ambient levels

456 During the observation period, we utilized 2,4-dinitrophenylhydrazine (DNPH)

457 cartridge and high-performance liquid chromatography (HPLC) analysis technique to

458 quantify 15 carbonyl compounds. The concentrations and relative proportions of these

459 compounds are summarized in Table 1. The average total concentration of the 15

460 carbonyls in the CUPA was 17.4 ± 5.3 ppb. Overall, areas with elevated concentrations

461 of carbonyl compounds were primarily concentrated in and around Chengdu in both

462 northern and southern directions. MY site, located to the north of Chengdu, exhibited

463 the highest concentration of carbonyl compounds (35.2 ± 13.4 ppb), while YA site,

464 situated southwest of Chengdu, showed the lowest concentration (10.7 ± 4.2 ppb).

465

466 **Table 1.** Daily mean \pm standard error of carbonyl compound mixing ratios (ppbv) at each site in
 467 the CPUA during the observation period. Sum: the total sum of carbonyl compound mixing ratios
 468 across all compounds at each site.

Carbonyls	MY	DY	CDHKY	XJ	SN	ZY	MS	YA	LS
formaldehyde	12.8 \pm 6.5	6.1 \pm 2.8	10.1 \pm 4.2	8.9 \pm 4.4	7.0 \pm 3.6	5.8 \pm 2.7	8.5 \pm 4.2	6.4 \pm 2.4	6.6 \pm 3.4

469

470

471

472 Fig.S1 illustrates the relationship between ozone concentration and carbonyl
473 compounds concentration at each site during the observation period. It is evident that
474 the spatial distribution of carbonyl compound concentrations is similar to that of ozone
475 concentration. Regions with severe ozone pollution tend to exhibit higher
476 concentrations of carbonyl compounds. The variation in carbonyl compound
477 concentrations is primarily attributed to anthropogenic emissions and prevailing
478 summer wind directions in the CPUA. Chengdu is the most economically developed
479 city in the CPUA, with notably higher GDP and industrial production values than other
480 regions. Chengdu's major industries include coal-fired power plants, chemical plants,
481 metallurgy and building materials plants, and high concentrations of carbonyls were
482 observed in here. The unique basin climate of the CPUA, characterized by intense
483 sunlight and stable atmospheric conditions, facilitates the accumulation of pollutants.
484 Large amount of industrial emissions and strong photochemical reaction contributes to
485 ozone pollution. Additionally, during the summer, prevailing northerly winds in the
486 CPUA facilitate the downwind transport of pollutants from upwind sources, leading to
487 regional pollution. It is noteworthy that the concentration of carbonyl compounds at the
488 MY site significantly exceeds that at the CDHKY site. Mianyang, with its industrial
489 roots, consistently maintains its position as the second-highest GDP contributor in
490 Sichuan Province. The electronics information industry stands as Mianyang's primary
491 economic driver, constituting approximately half of the city's total output value. Studies
492 investigating the volatile organic compound (VOC) source profile in Chengdu(Zhou et
493 al., 2021) reveal that ethanol and carbonyls predominantly characterize electronics
494 manufacturing emissions.

495 3.2.2 Compositional characteristics

496 According to the composition characteristics of 15 carbonyl compounds in the
497 ambient air of each city during the observation period (Table S4) .Formaldehyde was

498 the most abundant carbonyl found in these sites followed by acetone and acetaldehyde,
499 which is widely observed in previous studies. The measured ratios of formaldehyde,
500 acetone, and acetaldehyde across different sites ranged from 36.4% to 59.4% (average
501 48.1%), 12.4% to 28.1% (average 19.9%), and 8.2% to 47.3% (average 17.5%),
502 respectively. In this study, the total measured of formaldehyde, acetaldehyde, and
503 acetone (FAT) account for over 78% of the total carbonyls concentrations. At the MY
504 and ZY sites, this proportion even exceeded 90%. It is noteworthy that isobutyraldehyde
505 (MACR) ranks fourth in the volume concentration of 15 carbonyls measured in the
506 ambient air surrounding XJ, accounting for 5.3%. MACR, a characteristic product of
507 isoprene photooxidation from biogenic sources, possibly originates from the abundant
508 vegetation surrounding XJ. It reflects the period's relatively active photochemical
509 reactions, with substantial contributions from secondary formation to the measured
510 carbonyls composition.

511 The observed levels of FAT in different areas were influenced by various factors
512 including sampling period, geographic location, meteorological conditions, chemical
513 removal, and source emissions(Z. Zhang et al., 2016). Despite these influences,
514 comparisons remain valuable in providing an overview of ambient carbonyl levels in
515 the CPUA. During the summer of 2010, a national wide survey of ambient
516 monocarbonyl compounds were conducted simultaneously in nine sites (Ho et al.,
517 2015)found that the total FAT concentration was highest in Chengdu (14.96 ppb),
518 followed by Beijing (11.83 ppb), and Wuhan (11.70 ppb). Beijing, as the capital of
519 China, and Wuhan, being one of the top ten most populous cities in China, played
520 significant roles in this comparison. In our study, the CDHKY site within CPUA
521 exhibited the highest FAT concentration, with values of 18.25 ppb, surpassing those
522 recorded in 2010. Furthermore, the total FAT concentrations observed at the CPUA and
523 XJ sites, with values of 14.99 ppb and 14.90 ppb respectively in our study, closely
524 resemble those reported in August 2010 in Chengdu. The consistently high levels of
525 carbonyl compounds observed in Chengdu, both in 2010 and our current study, indicate

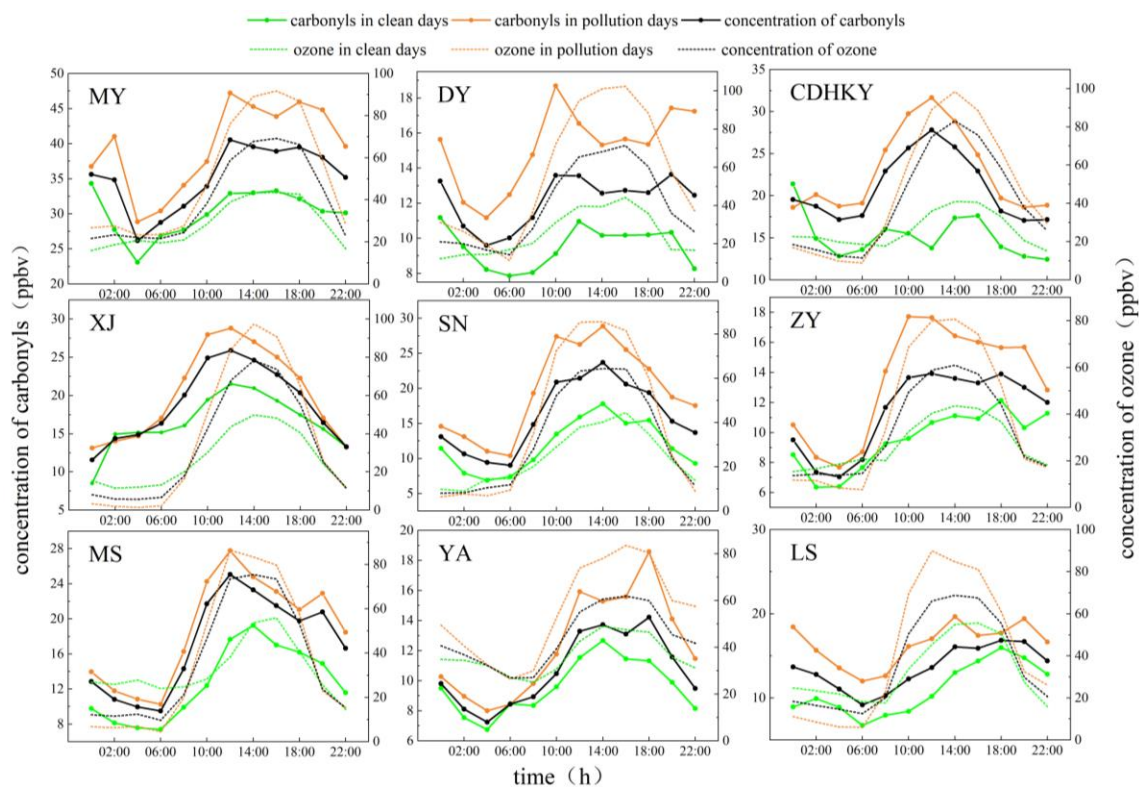

526 that the city likely experiences higher concentrations of these pollutants compared to
527 other regions across the country. However, more extensive temporal data would be
528 beneficial to fully validate this pattern at a national scale. Comparing our findings to
529 international studies, the FAT concentrations at the CDHKY site were lower than those
530 reported in Rio De Janeiro, Brazil(da Silva et al., 2016), during July to October 2013
531 (35.43 ppb), but higher than those in Bangkok, Thailand(Kanjanasiranont et al., 2016b),
532 Orleans, France(Jiang et al., 2016), and the United States(Murillo et al., 2012), with
533 values of 9.05 ppb, 6.12 ppb, and 5.76 ppb, respectively.

534 3.3 Temporal variations of carbonyl compounds

535 The diurnal variation of the total mixing ratio of ambient carbonyl compounds and
536 ozone concentration around each site in the CPUA during the observation period is
537 shown in Fig. 4. According to the observation results, the diurnal trend of ozone
538 concentration at each site showed a "unimodal" variation characteristic, that was, it
539 gradually increased from the morning to the peak of one day at noon, and then decreased.
540 The diurnal variation of the total mixing ratio of carbonyl compounds at each site
541 generally showed a characteristic of high during the daytime and low at night. The
542 concentration of carbonyl compounds during the day (6:00-16:00) was 48.8% higher
543 than that at night (18:00-4:00) at the XJ site. This indicated that the concentration of
544 carbonyl compounds increased by photochemical production during the daytime.
545 Additionally, deposition processes, particularly dry deposition at night, likely
546 contribute to the observed diurnal variation in carbonyl levels. The diurnal variation
547 characteristics of each site were different. For example, the diurnal variation
548 characteristics of carbonyl compounds concentration at CDHKY, XJ and SN sites were
549 consistent with those of ozone. The diurnal variation of carbonyl compounds
550 concentrations at other sites showed "double peaks", peaking at 10:00-12:00 and 18:00-
551 20:00, respectively. The concentrations of carbonyl compounds at night were also
552 higher at MY, DY and LS sites. The diurnal minimum values of the total concentration
553 of carbonyl compounds and ozone concentration appeared at similar time, usually at

554 4:00 a.m. or 6:00 a.m. The first peak of the total mixing ratio of carbonyl compounds
 555 occurred earlier than the maximum ozone concentration of the day. The first peak of
 556 the total mixing ratio of carbonyl compounds mostly occurred between 10:00 and 12:00.
 557 And the maximum ozone concentration mostly occurs between 14:00 and 16:00. This
 558 was related to the fact that carbonyl compounds were important precursors of ozone.

559 In general, the diurnal variation of the total concentration of carbonyl
 560 compounds on pollution days and clean days was high during the daytime and low at
 561 night. The total mixing ratio of carbonyl compounds on pollution days was 22.8%-
 562 66.2% higher than that on clean days. At the same time, the increase of concentration
 563 of carbonyl compounds during the daytime on pollution days was higher than that on
 564 clean days. This suggested that the increase in the concentration of carbonyl
 565 compounds during the daytime contributed to ozone pollution.

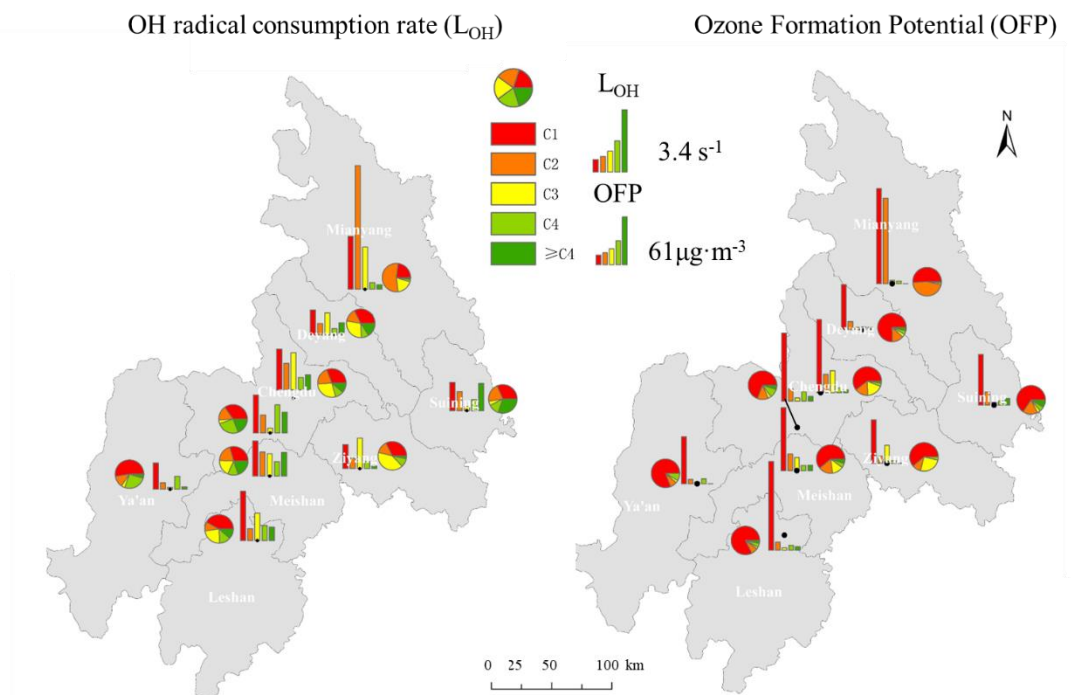

566
 567 **Figure 4.** Diurnal variations of carbonyl compounds and ozone concentrations at each site in the
 568 CPUA during the observation period

569 **3.4 Atmospheric photochemical reactivity of carbonyl compounds**

570 During the observation period, the total OH radical consumption rate (L_{OH}) and

571 total ozone formation potential (OFP) of the 15 carbonyl compounds at each site are
 572 depicted in Fig.5. The ranking of total L_{OH} and total OFP at each site is consistent,
 573 except for the YA and ZY sites with lower concentrations of carbonyl compounds,
 574 where the atmospheric photochemical reactivity ranking also aligns with the
 575 concentration. Among all sites, the MY and CD sites display the highest reactivity,
 576 while the YA and ZY sites exhibit the lowest reactivity. During the observation period,
 577 carbonyl compounds significantly contributed to ozone formation. The contributions to
 578 total VOCs (alkanes, alkenes, alkynes, aromatics, and carbonyl compounds) OFP at the
 579 MY, SN, ZY, YA, and LS sites ranged from 19.5% to 48.6%. Formaldehyde and
 580 acetaldehyde were identified as the most reactive species in the atmosphere, surpassing
 581 other carbonyl compounds in reactivity due to their higher concentrations and inherent
 582 reactivity, especially formaldehyde. However, acetone exhibited high inertness and a
 583 prolonged atmospheric lifetime, leading to its accumulation in ambient air with
 584 concentrations higher than other carbonyl compounds except for formaldehyde and
 585 acetaldehyde. Thus, despite its elevated concentration, acetone's reactivity remained
 586 relatively low.

587

588 **Figure 5.** L_{OH} and OFP of carbonyl compounds at each site in the CPUA during the observation

589

period

590 3.5 Sensitivity analysis of ozone formation based on formaldehyde to NO₂ ratio (FNR)

591 The change of O₃ formation sensitivity of each site in the CPUTA during the
592 observation period is shown in Fig.6. As can be seen from the Fig. 6, most sites remain
593 in the VOCs-limited regime during the cleaning period and EP1 to EP3. Economically
594 developed city such as Chengdu, Meishan, with high levels of formaldehyde and NO₂,
595 remain in the VOCs-limited regime. Ya'an as a city with the lowest GDP ranking in the
596 CPUTA, with low levels of formaldehyde and NO₂, remain in the transitional regime.

597

598 **Figure 6.** The change of O₃ formation sensitivity of each site in the CPUTA during the observation
599 period. The arrows represent time step from clean period to EP1 to EP2 to EP3.

600 The daily variation of O₃ formation sensitivity and ozone concentration at each
601 site in the CPUTA during the observation period is shown in Fig. S4. The mean FNR of
602 each site ranged from 0.48 to 1.29 during the observation period. The FNRs were lower
603 than 0.55±0.16 at XJ, DY, ZY, CDHKY, and MS, and higher than 1.0 at LS, SN, YA
604 and MY. At the same time, the mean ozone concentration at each site was between 138
605 and 192 μg·m⁻³. The mean ozone concentration in XJ, DY, CDHKY and MS was 166-
606 192 μg·m⁻³, it was 150-164 μg·m⁻³ in LS, SN, YA and MY. Therefore, it could be seen
607 that most of the sites with high mean ozone concentrations during the observation

608 period, like CDHKY, XJ, MS and Deyan sites, were in the VOCs-limited regime, and
609 most of the stations with low mean ozone concentrations during the observation period
610 such as YA, SN, MY and LS were in the transitional regime. It was worth noting that
611 the mean ozone concentration at ZY site (only $138 \mu\text{g}\cdot\text{m}^{-3}$) during the observation
612 period was much lower than that of other sites, but most of the ZY site was in VOCs-
613 limited regime, which was mainly related to the low concentration of formaldehyde. In
614 addition, the FNR value of the MY site was also relatively high, which was mainly
615 caused by the high concentration of formaldehyde.

616 Based on the ratio of formaldehyde to NO_2 mixing ratio, most sites remain in the
617 VOCs-limited regime during the observation period. And the sites with heavy ozone
618 pollution were in the VOCs-limited regime, and the sites with light ozone pollution
619 were in the transitional regime. Photochemical reactivity (L_{OH} and OFP) analysis
620 showed that formaldehyde and acetaldehyde contributed significantly to the
621 enhancement of atmospheric oxidation and ozone formation potential. Therefore, when
622 heavy ozone pollution occurs in the CPUA, special attention should be paid to the
623 control of VOCs, especially formaldehyde and acetaldehyde in carbonyl compounds,
624 under the coordinated control of NO_x and VOCs. Overall, this study reveals the
625 important contribution of carbonyl compounds to ozone pollution in the CPUA, and
626 provides scientific support for the establishment of ozone pollution prevention and
627 control measures.

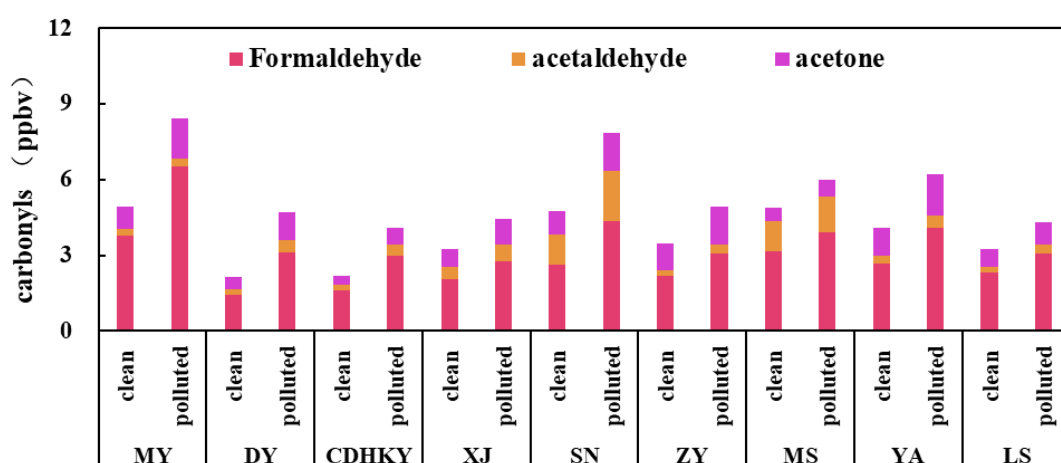

628 3.6 Source Analysis of carbonyl compounds

629 3.6.1 Quantitative source analysis of key carbonyl compounds

630 The table S7 provides a summary of the background and primary emissions
631 concentrations of formaldehyde, acetaldehyde, and acetone at nine sites across the eight
632 cities of the CPUA, along with the proportion of secondary formation contributing to
633 their concentrations. Background concentrations and primary emissions of
634 formaldehyde, acetaldehyde, and acetone ranged from 50% to 80%, 46% to 83%, and

635 45% to 78%, respectively. Secondary formation accounted for 20% to 50%, 17% to
 636 54%, and 22% to 55% of their concentrations, respectively. Notably, in SN and YA, the
 637 secondary formation of formaldehyde contributed half of the observed concentration,
 638 indicating it as the predominant source, while acetaldehyde's secondary formation also
 639 prevailed in these sites. Conversely, acetone, with lower reactivity, primarily originated
 640 from background concentrations and primary emissions at other sites except YA.
 641 Moreover, background concentrations and primary emissions were identified as the
 642 main contributors to carbonyl compounds in XJ and LS.

643 Fig.7 illustrates the secondary formation concentrations of formaldehyde,
 644 acetaldehyde, and acetone at each site in the CPUA under both clean and polluted
 645 conditions. Under polluted conditions, the secondary concentrations of formaldehyde,
 646 acetaldehyde, and acetone exceeded those in clean conditions by 58.8%, 54.6%, and
 647 57.6%, respectively. The most significant increases in secondary concentrations were
 648 observed at the SN site, while relatively smaller increases were observed at LS and XJ.

649
 650 **Figure 7.** Concentrations of formaldehyde, acetaldehyde and acetone in secondary formation
 651 under different pollution conditions at each site in the CPUA during the observation period

652 3.6.2 Exploration of secondary formation mechanism of key carbonyl compounds

653 In this study, we utilized VOC data collected on August 11, 12, and 16, when all
 654 eight cities in the CPUA were experiencing mild to severe ozone pollution. We
 655 calculated the Relative Incremental Reactivity (RIR) of formaldehyde, acetaldehyde,

656 and acetone at the MY, SN, ZY, YA, and LS sites on these days. The OBM analysis
 657 allowed us to assess the impact of anthropogenic VOCs (alkanes, alkenes, alkynes,
 658 aromatics) and biogenic VOCs (e.g., isoprene) on carbonyl compound formation in the
 659 context of regional ozone pollution events (Fig.8). Overall, the sensitivities of different
 660 anthropogenic source and plant source VOCs to formaldehyde, acetaldehyde and
 661 acetone was consistent among sites. For formaldehyde, reducing alkenes in
 662 anthropogenic source VOCs and plant VOCs was the most effective way to control
 663 formaldehyde concentration, while reducing alkenes in anthropogenic source VOCs
 664 was also beneficial to reduce the formation of acetaldehyde. For acetone with low
 665 reactivity, the alkanes in anthropogenic source VOCs were the most sensitive to the
 666 formation of acetone, followed by alkenes and BVOCs. Only the RIR value of alkanes
 667 were greater than zero, and the RIR values of both alkenes and BVOCs were less than
 668 zero, indicating that reducing alkanes could reduce the formation of acetone, while
 669 reducing alkenes and BVOCs was not conducive to acetone concentration control.

670
 671 **Figure 8.** Mean RIRs of formaldehyde, acetaldehyde and acetone to different anthropogenic
 672 source VOCs (alkanes (ALK), alkenes (ALE), alkynes(ACE), aromatics (ARO))and biogenic

673 VOCs (BVOCs) at MY, SN, ZY, YA and LS sites on August 11th, 12th and 16th.

674 3.6.3 Influence of regional transportation contribution

675 The TrajStat trajectory model was used to calculate and cluster the 24-hour
676 backward trajectories of air quality at the sampling sites. The backward trajectory
677 during sampling is shown in Fig.S5. During the observation period, the pollution of
678 carbonyl compounds in the cities of the CPUA was affected by the mutual transport
679 among cities in Sichuan Province, especially along the MY-DY-CDHKY route. In
680 addition, the surrounding provinces and cities of Sichuan Province (Gansu and
681 Chongqing) also contributed to the carbonyl compounds of the CPUA.

682 The potential sources of carbonyl compounds at different pollution stages at the
683 CDHKY during the observation period are shown in Fig. 9. It can be seen from the
684 figure that there are differences in the potential sources of carbonyl compounds among
685 different pollution stages at the CDHKY site. The concentration of local carbonyl
686 compounds in CDHKY was high during the early observation period and EP1, which
687 existed local sources, and was also affected by the northern airflow, and carbonyl
688 compounds was also affected by the transport from MY, DY and other northern regions.
689 Under the effect of the continuous northern airflow, the local source emissions
690 decreased during EP1, and the potential source of carbonyl compounds changed to from
691 the junction between CDHKY and ZY. During EP3, under the combined influence of
692 the western airflow, the contribution of transport from SN and ZY to carbonyl
693 compounds increased, while emissions from local sources also increased.

694

695 **Figure 9.** Analysis of potential sources of carbonyl compounds at different periods at the CDHKY

696 site during the observation period (a) August 4th-6th (b) August 7th-9th (c) August 10th-13th (d)

697

August 15th-18th

698 4. Conclusions

699 During a comprehensive atmospheric observation campaign conducted at nine
 700 sites across the CPOA from August 4th to 18th, 2019, three regional heavy ozone
 701 pollution episodes (EP1 to EP3) were observed. This study extensively examines the
 702 concentration variations, atmospheric chemical reactivity, and sources of carbonyls
 703 during this period. The average total concentrations of 15 carbonyl compounds across
 704 the nine sites within eight cities of the CPOA were measured at 17.4 ± 5.3 ppb. Spatial
 705 analysis indicated that areas with higher carbonyl concentrations were concentrated
 706 around Chengdu, extending both north and south. Notably, regions with elevated
 707 carbonyl compound concentrations also tended to experience more severe ozone
 708 pollution. Formaldehyde (36.4%-64.3%), acetone (12.4%-28.1%), and acetaldehyde
 709 (8.2%-47.3%) constituted the predominant species by volume concentration. Chengdu

710 exhibited FAT concentrations surpassing national and international levels, indicating
711 heightened levels compared to other regions.

712 Compared to clean days, carbonyl compound concentrations were significantly
713 higher on ozone pollution days, with increases ranging from 22.8% to 66.2%. Between
714 19.5% and 48.6% of the total volatile organic compound (VOC) ozone formation
715 potential (OFP) was attributed to the 15 carbonyl compounds, highlighting their
716 substantial contribution to ozone formation, particularly formaldehyde and
717 acetaldehyde. While primary emissions are the main sources of these compounds,
718 secondary formation processes contributed over 30% on average to the concentrations
719 of formaldehyde, acetaldehyde, and acetone. Under ozone pollution conditions, the
720 secondary formation concentrations of these three compounds were notably higher than
721 on clean days, with increases of 58.8%, 54.6%, and 57.6%, respectively, emphasizing
722 the critical role of secondary processes in exacerbating regional ozone pollution. OBM
723 modeling revealed that formaldehyde and acetaldehyde primarily originated from the
724 secondary formation of alkenes and BVOCs, while acetone mainly stemmed from the
725 secondary formation of alkanes. These findings highlight that while the concentration
726 of carbonyl compounds is important, their significant impact on ozone formation is
727 primarily driven by secondary chemistry. Specifically, the secondary formation of these
728 compounds from alkenes and biogenic BVOCs plays a key role in this process.

729 Ground-level observations of the formaldehyde to NO₂ ratio (FNR) were utilized
730 to assess the sensitivity of ground-level ozone formation. Analysis of FNR revealed that
731 sites experiencing heavy ozone pollution exhibited lower FNRs, indicating a VOCs-
732 limited regime, while sites with lighter ozone pollution were categorized into a
733 transitional regime. Furthermore, it is recommended to establish a scientific control
734 mechanism for both NO_x and VOCs, with special attention to formaldehyde,
735 acetaldehyde, and acetone, and their alkenes precursors. Additionally, considering the
736 regional nature of pollution, this study suggests that carbonyl compound pollution is
737 influenced by mutual transport among cities within the CPUA, notably along the MY-

738 DY-CDHKY route. Establishing a collaborative prevention and control mechanism
739 among cities within the CPUA and neighboring provinces and cities is crucial to
740 effectively address carbonyl compounds and ozone pollution in the region in the future.

741

742 **Data availability.** Observational data including meteorological parameters and air
743 pollutants used in this study are available from the corresponding authors upon request
744 (lihong@craes.org.cn).

745

746 **Author contributions.** Hong Li and Jiemeng Bao designed this study. Xin Zhang,
747 Zhenhai Wu, Jiemeng Bao, Li Zhou, Qinwen Tan, and Fumo Yang coordinated the
748 selection of field observation sites, including locations for both VOCs and carbonyls
749 grid sampling. Qinwen Tan and Hefan Liu supported the collection of carbonyls at one
750 site. Zhenhai Wu and Xin Zhang assisted in carbonyls sampling; Xin Zhang and
751 Yunfeng Li assisted in carbonyls sample analysis and data collection. Li Zhou and
752 Hefan Liu organized the analysis of VOCs measurements. Jun Qian, Junhui Chen, and
753 Liqun Deng provided support in project funding application. Jiemeng Bao performed
754 the data analysis and wrote the paper with contributions from all co-authors; Hong Li
755 reviewed the paper, provided comments and finalized it.

756

757 **Competing interests.** The contact author has declared that none of the authors has any
758 competing interests.

759

760 **Acknowledgments.** The authors would like to express their sincere appreciation to
761 Keding Lu and Xin Li of Peking University for their organization of the intensive field
762 observation experiment on the formation mechanisms of photochemical pollution in
763 summer in the CPUA of China. They also want to show their deep gratitude to Yulei
764 Ma, Tianli Song, Xiaodong Wu, Ning Wang, and He Zijun Liu of Sichuan University,
765 as well as Xin Zhang (female) and Hefan Liu of Chengdu Academy of Environmental

766 Protection Sciences for their help in sampling. They are also grateful to Liping Liu of
767 Sichuan Agricultural University in Ya'an City, Kaiyao Lv of Mianyang High-tech Zone
768 Management Committee, Yong Xiao of Deyang Municipal Education Bureau, Ying Ni
769 of Meishan Ecological Environment Bureau, Aihua Zou of Leshan Ecological
770 Environment Bureau, and Chuhan Wang of the Chinese Academy of Environmental
771 Sciences for their substantial support during field observations. Special thanks to Zhen
772 He and Manfei Yin of the Chinese Academy of Environmental Sciences for their
773 assistance in analyzing samples from the XJ site.

774

775 **Financial support.** This research has been supported by the Research Project on
776 Analysis of Multiple Causes of Atmospheric Ozone Pollution in Urban Agglomerations
777 of Chengdu Plain and Development of Management, Prevention, and Control System
778 of Sichuan Academy of Environmental Sciences (No. 510201201905430).
