2 **TEOS-10 and the Climatic Relevance of Ocean-Atmosphere Interaction**

3 Rainer Feistel

4 Leibniz Institute for Baltic Sea Research (IOW), 18119 Warnemünde, Germany

5 **Correspondence:** Rainer Feistel (rainer.feistel@io-warnemuende.de)

6 **Abstract:** Unpredicted observations in the climate system, such as recently an excessive ocean
7 warming, are often lacking immediate causal explanations and are challenging the numerical models.
8 As a highly advanced mathematical tool, the Thermodynamic Equation of Seawater – 2010 (TEOS-10)
9 had been established by international bodies as an interdisciplinary standard and is recommended
10 for use in geophysics, such as especially in climate research. From its very beginning, the
11 development of TEOS-10 was supported by *Ocean Science* through publishing successive stages and
12 results. Here, history and properties of TEOS-10 are briefly reviewed. With focus on the air-sea
13 interface, selected current problems of climate research are discussed and tutorial examples for the
14 possible use of TEOS-10 in the associated context are presented, such as related to ocean heat
15 content, latent heat and rate of marine evaporation, properties of sea spray aerosol, or climatic
16 effects of low-level clouds. Appended to this article, a list of publications and their metrics is
17 provided for illustrating the uptake of TEOS-10 by the scientific community, along with some
18 continued activities, addressing still pending, connected issues such as uniform standard definitions
19 of uncertainties, of relative humidity, seawater salinity or pH.

20 This article is dedicated to the Jubilee celebrating 20 years of Ocean Science.

40

41 **1 Introduction**

42 Quite recently in 2024, climate research has published alarming news: “The world’s oceans absorbed
43 more heat in 2023 than in any other year since records began in the 1950s. ... Data show that the
44 heat stored in the upper 2,000 metres of oceans increased by 15 zettajoules (1 zettajoule is 10^{21}
45 joules) in 2023 compared with that stored in 2022. This is an enormous amount of energy — for
46 comparison, the world’s total energy consumption in 2022 was roughly 0.6 zettajoules” (You 2024: p.
47 434). Dividing this value by the global ocean surface area and by the duration of a year, the reported
48 ocean’s average warming rate amounts to 1.3 W m^{-2} , and is apparently even counting. “The drivers
49 of a larger Earth energy imbalance in the 2000s than [before] are still unclear. ... Future studies are
50 needed to further explain the drivers of this change” (von Schuckmann et al. 2023). Laterally, the
51 observed heat excess is unevenly distributed over the world ocean (Fig. 1), in contrast to what
52 naively may be expected from rising atmospheric CO_2 concentrations. Rather, warming seems to be
53 most pronounced in the austral and boreal west-wind belts.

54

55 Fig. 1: Observed trend 1958 through 2022 of the upper 2000 m ocean heat content (WMO 2024).
56 Image reproduction permitted by WMO Copyright.

57

58 Sunlight is the only available heat source of sufficient power to cause the observed warming, while
59 the globally averaged geothermal heat flux is estimated to be just 0.087 W m^{-2} (Pollack et al. 1993),
60 and is not expected to suddenly rise recently due to human impact. Irradiation is hampered by
61 clouds, dust and absorbing gases, and water surface reflection such as by whitecaps, waves or
62 plankton layers. Heat absorbed in the water column may effectively exit the ocean again only across
63 the air-sea interface via sensible, radiative and latent heat flux. All these effects may vary in the
64 climate system in a complicated, mutually interacting manner. Typically, present numerical climate
65 models suffer from an “ocean heat budget closure problem” (Josey et al. 1999) and describe the
66 ocean-atmosphere heat flux only to within uncertainties between 10 W m^{-2} and 30 W m^{-2} (Josey et
67 al. 2013). According to recent model comparison studies, many of those “models fail to provide as
68 much heat into the ocean as observed” (Weller et al. 2022: p. E1968). Dynamical models, rather than
69 observed correlations, are the most reliable tools for the detection and verification of causal
70 relations (Feistel 2023), however, such as in this case of air-sea interaction, large uncertainties may
71 prevent any significant conclusions to be drawn regarding the causes of the observed ocean warming
72 rate of 1.3 W m^{-2} .

73 Of the increasing amount of water vapour contained in the global troposphere, 85 % result from
74 ocean evaporation (Gimeno et al. 2013). Corresponding to 1200 mm annual evaporation

75 (Baumgartner and Reichel 1975, Peters-Lidard et al. 2019), the associated latent heat flux of about 95
76 W m^{-2} per ocean surface area represents the strongest energy supply for the atmospheric dynamics
77 (Albrecht 1940) and at the same time the strongest cooling process of the sea. This flux depends
78 sensitively on the relative humidity (RH) at the water surface; an RH increase by 1 %rh can be
79 estimated to reduce evaporation by 5 W m^{-2} (Feistel 2015, Feistel and Hellmuth 2021, 2023), so that
80 minor additional 0.2 %rh may already suffice to warm up the ocean by the observed 1.3 W m^{-2} .
81 Unfortunately, marine RH is observed only with uncertainties between 1 and 5 %rh (Lovell-Smith et
82 al. 2016), or, accordingly, between 5 and 25 W m^{-2} of latent heat flux. It remains unclear to what
83 extent minor, yet unnoticed changes in marine RH may be responsible for the recent ocean warming.

84

85 Fig. 2: Heat fractions stored additionally in the different parts of the Earth system 1960–2020 (values
86 from von Schuckmann et al. 2023), represented graphically by partial areas. Obviously, the oceans
87 dominate global warming.

88

89 According to Fig. 2, a paramount share of 94 % of global warming occurs in different phases and
90 geophysical mixtures of water, in particular in seawater. Considering this situation, the *Scientific*
91 *Committee on Oceanic Research* (SCOR) in cooperation with the *International Association for the*
92 *Physical Sciences of the Oceans* (IAPSO) decided at its 2005 Cairns meeting the establishment of the
93 *SCOR/IAPSO Working Group 127 on Thermodynamics of Seawater* (Millero 2010, Pawlowicz et al.
94 2012), which held its inaugural meeting in 2006 at Warnemünde (Fig. 3). It had been recognised that
95 “modeling of the global heat engine needs accurate expressions for the entropy, enthalpy, and
96 internal energy of seawater so that heat fluxes can be more accurately determined in the ocean”
97 (Millero 2010: p. 28) while such properties were not available from the thermodynamic seawater
98 standard at that time, the 1980 Equation of State of Seawater (EOS-80) (Fofonoff and Millard Jr.
99 1983).

100 The foundation of WG127 happened almost coincidentally with the establishment of the *Ocean*
101 *Science* journal of the *European Geosciences Union* (EGU) in 2004/05. The development of the new
102 standard by WG127, the Thermodynamic Equation of Seawater – 2010 (TEOS-10) was very
103 successfully supported by Ocean Science, publishing the Special Issue #14 on “Thermophysical
104 Properties of Seawater” with 16 articles between 2008 and 2012 (Feistel et al. 2008a). **Appendix A**
105 reports the current metrics of this Special Issue. Also in 2008, at its conference in Berlin, Germany,
106 the *International Association for the Properties of Water and Steam* (IAPWS) established a new
107 *Subcommittee on Seawater* (SCSW) that cooperated closely with WG127. In the form of carefully

108 verified mathematical formulations for properties of water, ice, seawater and humid air, IAPWS
109 adopted 9 fundamental documents related to TEOS-10 (IAPWS AN6-16 2016), see **Appendix A**.

118 Picard (BIPM, deceased 2015), Petra Spitzer (WG127), Rainer Feistel (WG127), Michael Kühne
119 (director BIPM), Andy Henson (BIPM), Robert Wielgosz (BIPM).

120

121 With respect to problems yet pending after the official adoption of TEOS-10, especially for the
122 preparation of future novel international definitions of seawater salinity, seawater pH and
123 atmospheric relative humidity (Feistel et al. 2016, Pawlowicz et al. 2016, Dickson et al. 2016, Lovell-
124 Smith et al. 2016), the standing *IAPSO/SCOR/IAPWS Joint Committee on the Properties of Seawater*
125 (JCS) was established in 2012. In 2011, IAPWS also extended its cooperation with the *International*
126 *Bureau for Weights and Measures* (BIPM), see Fig. 4. Further details on TEOS-10 (IOC et al. 2010,
127 McDougall et al. 2013, Feistel 2018, Wikipedia 2024) are available from the TEOS-10 homepage,
128 www.teos-10.org, and are briefly reviewed in **Section 2** and **Appendix B**.

129 In the context of the predecessor EOS-80, the *ocean heat content* (OHC) was defined in terms of
130 *potential temperature* (Abraham et al. 2013). Improving this method, TEOS-10 entropy and enthalpy
131 of seawater provided a proper quantitative basis for a novel, thermodynamically rigorous definition

132 of the OHC in the form of seawater *potential enthalpy* (McDougall 2003, McDougall et al. 2013,
 133 Graham and McDougall 2013, McDougall et al. 2021), equivalently defined as *conservative*
 134 *temperature* and briefly discussed in **Section 3**.

135 Currently implemented parameterisations of marine evaporation rates in the form of historical
 136 *Dalton equations* (Stewart 2008, Josey et al. 2013) may be replaced by TEOS-10 chemical potentials
 137 which provide the proper quantitative basis for a thermodynamically rigorous formulation of non-
 138 equilibrium Onsager forces and fluxes in terms of *relative fugacity* (RF) of humid air (Kraus and
 139 Businger 1994, Feistel and Lovell-Smith 2017, Feistel and Hellmuth 2023, 2024a), as described in
 140 **Section 4**. *Relative humidity* (RH) is defined relative to the saturation state of moist air, which in turn
 141 is controlled by the chemical potentials of water in the gas and liquid phase. It is only natural,
 142 therefore, to define RH in terms of chemical potentials, which in fact is performed by RF. The
 143 uncertainty of latent heat flux with respect to the uncertainty of surface RH observation is shown to
 144 be significantly larger than the observed warming of 1.3 W m^{-2} , so that this warming may or may
 145 not be caused by so-far ignored minor RH increase.

146 The conceptual model of sea air as a two-phase composite thermodynamic system is outlined in
 147 **Section 5**. The roles of enthalpy, chemical potential and entropy are explained by means of explicit
 148 theoretical descriptions of three simplified tutorial examples, (i) for the latent heat of evaporation,
 149 (ii) for the heat capacity of humid air containing sea spray, and (iii) for the entropy production of
 150 irreversible evaporation.

151

152 Fig. 5: Schematic of *cloud radiation effects* (CRE). The *short-wave effect* (SW CRE) controls the
 153 downward flux of solar irradiation while the *long-wave effect* governs the infrared radiation balance
 154 between water surface and cloud base. By thermal convection, cumulus clouds emerge at the
 155 isentropic *lifted condensation level* (LCL). Figure from Feistel and Hellmuth (2024b)

156

157 Clouds do not only release the latent heat which water vapour has carried away from the ocean, they
 158 also interfere substantially in the global radiation balance, cooling the surface by reflecting short-
 159 wave solar irradiation, and warming the surface by sending back down long-wave thermal radiation,
 160 see Fig. 5. In the course of global warming, cloudiness has been found to exhibit a systematic trend of
 161 reduction, see **Section 6**, which affects the ocean heat content in a non-trivial, non-uniform manner.
 162 Marine cumulus clouds form by isentropic uplift of thermal convection. Their height controls their
 163 temperature and thermal downward radiation, affecting the ocean's energy balance. Updating
 164 previous results (Romps 2017) for the *lifted condensation level* (LCL) of marine cumulus clouds to
 165 thermodynamically rigorous TEOS-10 standard equations (Feistel and Hellmuth 2024b), the radiative

166 effect of those clouds can be estimated from *sea-surface temperature* (SST) and surface relative
167 humidity. This effect turns out to be weakly cooling and cannot provide a reasonable explanation for
168 the so-far unclear strong ocean warming.

169 **Section 7** provides a summary of this paper, **Appendix A** reports collections of publications with
170 respect to TEOS-10 as well as their metrics, and **Appendix B** offers a short introduction into the
171 concept of thermodynamic potentials.

172

173 2 Thermodynamic Equation of Seawater – 2010 (TEOS-10)

174 In the climate system, the omnipresent and dominant substance is water in various phases and
175 mixtures. For example, “water vapor is by far the most important greenhouse gas, in the sense that it
176 absorbs more irradiance from the Earth than all other greenhouse gases combined” (Rapp 2014: p.
177 381). Textbooks and other publications offer numerous collections of various different property
178 equations for water, ice, seawater or moist air, but uncertainties and mutual consistencies of those
179 equations are often unclear. To improve this situation, a novel *Thermodynamic Equation of Seawater*
180 – 2010 (TEOS-10) was developed by the members of the SCOR/IAPSO Working Group 127 (WG 127)
181 in close cooperation with the International Association for the Properties of Water and Steam
182 (IAPWS). TEOS-10 is described in a detailed Manual (IOC et al. 2010) and has been adopted and
183 recommended by IOC-UNESCO (2009) in Paris and by the IUGG (2011) in Melbourne, see also Feistel
184 (2008b, 2012, 2018), Valladares et al. (2011) and Pawlowicz et al. (2012). Starting in 2008 with a
185 Special Issue of *Ocean Science* (Feistel et al. 2008a), a large number of scientific publications has
186 appeared in the meantime, supporting, extending or exploiting TEOS-10. A collection of selected
187 papers related to TEOS-10 is summarised in Appendix A together with metrics that illustrate the
188 growing uptake of TEOS-10 by the scientific community.

189 The development of the first numerical thermodynamic Gibbs potentials (see Appendix B) for
190 seawater (Feistel 1991, 1993, Feistel and Hagen 1995) was based on the works of Millero and Leung
191 (1976) and Millero (1982, 1983), together with high-pressure background data of the previous EOS-
192 80 standard (Unesco 1981). Independently of that, a Helmholtz potential for pure fluid water had
193 been adopted by IAPWS in 1996 at Fredericia (Harvey 1998, Wagner and Pruß 2002). These were the
194 key activities which eventually culminated in the formulation of TEOS-10 about two decades later. By
195 combining those equations for pure and seawater, some known pending problems of EOS-80
196 (Fofonoff and Millard Jr. 1983) could incidentally be resolved (Feistel 2003). In the end, TEOS-10 has
197 been assembled from four basic thermodynamic potentials derived from mutually consistent, most
198 comprehensive and accurate datasets of measured properties available at that time. Those
199 potentials are:

- 200 (i) A Helmholtz function of fluid water, $f^F(T, \rho) \equiv f^W(T, \rho) \equiv f^V(T, \rho)$, known as the
201 IAPWS-95 formulation (Wagner and Pruß 2002), which is identical for liquid water,
202 $f^W(T, \rho)$ and for water vapour, $f^V(T, \rho)$. It describes de-aerated water of a fixed
203 isotopic composition, termed *Standard Mean Ocean Water* (SMOW).
204
- 205 (ii) A Gibbs function of ambient hexagonal ice I, $g^{Ih}(T, p)$, or IAPWS-06 formulation (Feistel
206 and Wagner 2006), see Tables A2 and A3 of Appendix A.
207
- 208 (iii) A Gibbs function of *IAPSO Standard Seawater*, $g^{SW}(S, T, p)$, or IAPWS-08 formulation
209 (Feistel 2008a), see Tables A2 and A3 of Appendix A. The variable S , at which a subscript
210 A is omitted here for simplicity, is the specific or *absolute salinity*, the mass fraction of

211 dissolved salt in seawater, which differs from practical salinity, S_p , measured by
212 oceanographic instruments (Millero et al. 2008). Sea salt is assumed to have
213 stoichiometric *Reference Composition*. The pure-water limit, $g^{SW}(0, T, p) = g^W(T, p)$, is
214 the Gibbs function of liquid water computed from the IAPWS-95 Helmholtz function
215 $f^W(T, \rho)$. For brackish seawater, g^{SW} has implemented Debye's root law of dilute
216 electrolyte solutions (Landau and Lifschitz 1966, Falkenhagen et al. 1971).

217
218 (iv) A Helmholtz function of humid air, $f^{AV}(A, T, \rho)$, or IAPWS-10 formulation (Feistel et al.
219 2010a), see Tables A1 and A2 of Appendix A. The variable A is the mass fraction of dry air
220 admixed with water vapour, so that $q = 1 - A$ is the *specific humidity*. The dry-air limit
221 $f^{AV}(1, T, \rho) = f^A(T, \rho)$ equals, up to modified reference-state conditions, the equation
222 of state of Lemmon et al. (2000). The air-free limit $f^{AV}(0, T, \rho) = f^V(T, \rho)$ equals the
223 IAPWS-95 Helmholtz function. In f^{AV} , the interaction of water vapour with dry air is
224 described by 2nd and 3rd virial coefficients.

225
226 Thermodynamic potentials include certain adjustable constants expressing the absolute energies and
227 entropies of the particular substances, which are not available from measurement (Planck 1906,
228 Feistel 2019) and have, in turn, no effect on measurable properties derived from those potentials.
229 The TEOS-10 reference states (Feistel et al. 2008b, 2010a) are the triple point of water, $T_{TP} =$
230 273.16 K, $p_{TP} = 611.654\ 771$ Pa, where the conditions

$$231 \eta_{TP}^W = 0, \quad e_{TP}^W = 0, \quad (1)$$

232
233 are imposed, and the standard ocean state, $S_{SO} = 35.165\ 04$ g kg⁻¹, $T_{SO} = 273.15$ K, $p_{SO} =$
234 $101\ 325$ Pa, with the conditions for sea salt,

$$235 \eta_{SO}^{SW} = 0, \quad h_{SO}^{SW} = 0, \quad (2)$$

236
237 and for dry air,

$$238 \eta_{SO}^A = 0, \quad h_{SO}^A = 0. \quad (3)$$

239
240 Here, η , e and h , respectively, are specific entropy, internal energy and enthalpy of those substances.
241 The TEOS-10 potential functions and properties derived thereof are numerically implemented in two
242 different libraries, the Sea-Ice-Air (SIA) and the Gibbs-Seawater (GSW) libraries, see Table A4 in
243 Appendix A.

244
245 The SIA library includes empirical coefficients only in the four fundamental potentials (Feistel 2010d,
246 Wright et al. 2010). All other potential functions and properties are derived strictly by mathematical
247 operations to ensure consistent results, even at the cost of low computation speeds as a result of
248 stacked iteration procedures. All quantities are exclusively expressed in basic SI units such as kg, m, J
249 or Pa. A more recent extension of SIA code is reported in Feistel et al. (2022) for the computation of
250 relative fugacity.

251
252 The GSW library is tailored for oceanographic models, optimised in computation speed (Roquet et al
253 2015). For fast numerical evaluation, GSW procedures contain new empirical coefficients determined
254 from the SIA library functions by regression. Units and variables are adjusted to common
255 oceanographic practice such as pressure in decibars relative to surface pressure, or temperatures in

259 °C. *Conservative Temperature* (CT) is used as a new preferred thermal variable. An additional
260 thermodynamic potential has been constructed (McDougall et al. 2023) that supports the use of CT
261 universally as an independent variable.

262

263 3 Potential Enthalpy and Ocean Heat Content (OHC)

264 Thermodynamically, the term “Ocean Heat Content” (OHC) is a sloppy wording. “Content” means a
265 state quantity of a body or volume while, however, “heat” is an exchange quantity rather than a
266 state quantity. “The obsolete hypothesis of heat being a substance is excluded” (Sommerfeld 1988:
267 p. 6). This distinction is qualitatively fundamental (Feistel 2023). Physical conservation quantities
268 such as energy or mass have the key property that the change of that quantity in a volume equals the
269 flux of that quantity across the boundary (Landau and Lifschitz 1966, Glansdorff and Prigogine 1971),
270 but this does not apply to “heat”. For example, a heat engine receives a permanent net heat flux
271 without getting permanently hotter. While asking how much “heat” is contained in the ocean may
272 find ambiguous answers, it is well defined to say how much heat has entered or left the ocean across
273 its boundary by a specified process that transfers the ocean from a certain state of reference to the
274 current state of interest. In this section, based upon TEOS-10, related states and processes are
275 described which may properly specify what is commonly termed OHC. This consideration intrinsically
276 connects OHC with ocean-atmosphere exchange processes relevant for climate change.

277 Since a long time, measuring and calculating the ocean’s “heat” has been a question of central
278 interest to oceanography. Recently, this issue has become even more important and urgent in the
279 context of climate change. “The total energy imbalance at the top of atmosphere is best assessed by
280 taking an inventory of changes in energy storage. The main storage is in the ocean” (Abraham et al.
281 2013: p. 450). The conventional approach is a formally defined mathematical procedure based on
282 potential temperatures. “Changes to ocean heat content (OHC) can be calculated from
283 measurements of the temperature evolution of the ocean. The OHC is attained from the difference
284 of the measured potential temperature profile and the potential temperature climatology. This
285 difference is integrated over a particular reference depth (for instance, 700 m) and is multiplied by a
286 constant ocean density reference and heat capacity” (Abraham et al. 2013: p. 468). However, this
287 OHC definition has no rigorous thermodynamic justification, and the relation to processes of ocean-
288 atmosphere heat fluxes is not entirely clear. If a sea-air heat flux of 1 W m^{-2} warms up the
289 atmosphere, by what rate exactly will that OHC decrease?

290 Making the seawater properties entropy and enthalpy quantitatively available, TEOS-10 has offered a
291 thermodynamically improved option for defining OHC (McDougall et al. 2021), in the form of the
292 integral over the ocean volume,

$$293 \text{OHC} = \int h^{\text{SW}}(S, \eta, p_0) \rho^{\text{SW}}(S, \eta, p) dV. \quad (4)$$

294 Here, $h^{\text{SW}}(S, \eta, p_0)$ is the *potential enthalpy* (McDougall 2003) relative to the surface pressure, p_0 ,
295 and $\rho^{\text{SW}}(S, \eta, p)$ is the in-situ mass density at the pressure p of a parcel with salinity and entropy
296 equal to those before. This definition can be understood in terms of both, a specified process of heat
297 exchange, and a reference state relative to which OHC is counted, as follows:

- 298 (i) A virtual **heat exchange process** supporting the definition (4) is sketched in Fig. 6. In turn,
299 each ocean parcel with in-situ properties (S, η, p) is lifted to the surface pressure p_0 ,
300 keeping its salinity and entropy constant. There, it reversibly exchanges heat, $dh = Td\eta$,
301 with a measuring device until the parcel’s entropy has reached a certain reference value,
302 η_{ref} , while the parcel’s salinity remains unchanged. Subsequently, the heat is reversibly

303 put back to the parcel which is then returned to its original location. The work required
 304 to lift and lower the parcel is balanced.
 305 (ii) The **reference state** relative to which OHC is measured is arbitrary and may be chosen by
 306 convenience or usefulness. In eq. (4), this state is defined by η_{ref} which satisfies
 307 $h^{\text{SW}}(S, \eta_{\text{ref}}, p_0) = 0$.

308 An alternative choice for the reference value of entropy, up to which the heat exchange with the
 309 surface instrument is performed, could be $\eta_{\text{ref}} = 0$, in which case the definition (4) became

$$310 \text{OHC}^* = \int [h^{\text{SW}}(S, \eta, p_0) - h^{\text{SW}}(S, 0, p_0)] \rho^{\text{SW}}(S, \eta, p) dV. \quad (5)$$

311 Because entropy is conserved during the vertical excursion processes, the latter reference state of
 312 the ocean is given by zero entropy all over the volume. In the case of (4), the alternative reference
 313 state is zero potential enthalpy (or zero Conservative Temperature, McDougall 2003) of all ocean
 314 parcels.

315
 316 Fig. 6: Schematic of a conceptual process defining the ocean heat “content” (OHC) by measuring heat
 317 flux across the ocean boundary according to eq. (4).

318

319 In a sense consistent with the previous OHC definition (Abraham et al. 2013), also a climatological
 320 average state could in principle be chosen as the OHC reference. However, this option includes the
 321 problem that the salinity distribution of the current ocean may differ from the reference ocean, and
 322 that thermodynamically properly treating the required salt exchange processes at the surface may
 323 turn the issue unnecessarily complicated.

324

325 4 Relative Fugacity and Ocean Evaporation Rate

326 In the past, several climate researchers have argued that along with global warming the marine
 327 evaporation has or will be “amplified” or “intensified” (Feistel and Hellmuth 2021). However, it was
 328 not always made clear whether this may mean that (a) in the course of a year, more water vapour is
 329 transferred from the global ocean to the atmosphere, or (b) that the global mean evaporation rate
 330 remains unchanged while locally or temporally, evaporation is more intense, or (c) any combination
 331 of the two variants. Conclusions of kind (a) were drawn by renowned climatologists such as Budyko
 332 (1984), Flohn et al. (1992), Yu (2007), Randall (2012) or Zhang et al. (2021).

333 By contrast, the currently observed ocean warming at a rate about 1 W m^{-2} does not support
 334 assumptions of an enhanced hydrological cycle with related latent-heat cooling, rather, it more likely
 335 suggests its slight reduction of evaporation. Two decades ago, Held and Soden (2006: p. 5687-89)
 336 had already clearly stated that “it is important that the global-mean precipitation or evaporation,
 337 commonly referred to as the strength of the hydrological cycle, does not scale with Clausius–
 338 Clapeyron. ... We can, alternatively, speak of the mean residence time of water vapor in the
 339 troposphere as increasing with increasing temperature.” Subsequent observations have underpinned
 340 their statement.

341 Between 1979 and 2022, annual mean global precipitation values, see Figure 7, fluctuated by about
 342 $\pm 10 \text{ mm yr}^{-1}$, in particular due to La Niña events, but do not exhibit a significant long-term trend
 343 (Vose et al. 2023). Under the common assumption that global precipitation is balanced against
 344 evaporation, no substantial strengthening of the hydrological cycle may be observed yet.

345

346 Fig. 7: Global mean precipitation anomaly 1979-2022 in mm yr^{-1} . The values displayed exhibit a minor
 347 increasing trend (dotted line) of 0.06 mm yr^{-2} . Data from Vose et al. (2023)

348

349 Probably, the minor trend of 0.06 mm yr^{-2} of the data displayed in Fig. 7 is statistically insignificant.
 350 Associated with this apparent trend, the latent heat transferred to the troposphere can be estimated
 351 to a negligible putative warming rate of additional 0.5 mW m^{-2} per year, which could explain only 10
 352 % of observed atmospheric warming by 1.7 °C per century (Morice et al. 2012, Feistel and Hellmuth
 353 2021).

354 The thermodynamic driving force for evaporation is the difference between the chemical potentials
 355 of water in humid air and in seawater at the two sides of the sea-air interface (Kraus and Businger
 356 1994). TEOS-10 has made this difference numerically available in the form of the water mass
 357 evaporation rate (Feistel and Hellmuth 2022, 2023)

$$358 \quad J_W = -D_f(u) \ln \frac{\psi_f}{x_W}. \quad (6)$$

359 Here, $D_f(u)$, is an empirical transfer coefficient as a function of the wind speed, u , and x_W is the
 360 mole fraction of water in seawater. Consistent with Wüst (1920), for the standard ocean with
 361 Reference Composition, this fraction is (Millero et al. 2008: Table 4),

362
$$x_W = \frac{53.556\ 514\ 4}{54.676\ 283\ 8} = 0.979\ 52. \quad (7)$$

363 In eq. (6), the sea-surface humidity is expressed by the relative fugacity (RF), ψ_f , defined by the ratio
 364 of the water-vapour fugacity in humid air, f_V , to that fugacity at saturation, f_V^{sat} (Feistel and Lovell-
 365 Smith 2017), see eq. (49). In ideal-gas approximation, RF equals conventional RH (Lovell-Smith et al.
 366 2016)

367
$$\psi_f \equiv \frac{f_V}{f_V^{\text{sat}}} \approx \psi_x \equiv \frac{x}{x^{\text{sat}}}. \quad (8)$$

368 Here, the mole fraction of water vapour in humid air is x , and its value at saturation is x^{sat} . Further,
 369 ψ_x is the conventional definition of RF in metrology and meteorology (Lovell-Smith et al. 2016).
 370 Independent of ideal-gas conditions, but sufficiently close to saturation, such as near the sea surface,
 371 RF can be estimated in excellent approximation from the Clausius-Clapeyron formula (Feistel et al.
 372 2022),

373
$$\psi_f \approx \exp\left\{\frac{L(T_{\text{dp}}, p)}{R_W}\left(\frac{1}{T} - \frac{1}{T_{\text{dp}}}\right)\right\}. \quad (9)$$

374 The evaporation enthalpy of pure water (IAPWS SR1-86 1992) at the dewpoint T_{dp} is L , and $R_W =$
 375 $461.523\ \text{J kg}^{-1}\ \text{K}^{-1}$ is the specific gas constant of water. The typical marine RF is

376
$$\psi_f \approx 80\ \text{‰rh}, \quad (10)$$

377 and is fairly independent of region, season or global warming (Dai 2006, Randall 2012, Rapp 2014,
 378 MetOffice 2020). Indeed, observed ocean surface RH has no significant climatological trend (Willett
 379 et al. 2023). Similarly, observed ocean wind speeds seem to be unaffected by global warming (Azorin-
 380 Molina et al. 2023). Eq. (6) for the evaporation rate depends only on wind speed and RF, so that it
 381 may be concluded that also the global mean evaporation rate has no significant climatic trend.
 382 Hence, the TEOS-10 approach in the form of eq. (6) appears to be consistent with the prediction of
 383 Held and Soden (2006).

384 Various empirical evaporation equations, commonly known as *Dalton equations*, are found in the
 385 literature (Wüst 1920, Sverdrup 1936, 1937, Montgomery 1940, Debski 1966, Baumgartner and
 386 Reichel 1975). Several numerical climate models estimate evaporation from the formula (Stewart
 387 2008),

388
$$J_W = D_q(u)(q_0 - q_{10}), \quad (11)$$

389 where q_0 is the specific humidity at the sea surface and q_{10} is that at 10 m height, or from (Josey et
 390 al. 1999, 2013)

391
$$J_W = D_q(u)(0.98\ q^{\text{sat}} - q). \quad (12)$$

392 Here, q is the near-surface specific humidity, and q^{sat} is the saturation value at the same
 393 temperature and pressure. The factor 0.98 accounts for the salinity, see eq. (7). After a few
 394 approximation steps (Feistel and Hellmuth 2023), these Dalton equations can be derived from the
 395 TEOS-version, eq. (6), however, there is an important qualitative difference. At constant RH, due to
 396 global warming, specific humidities such as q and q^{sat} , as well as their difference, are increasing
 397 following the Clausius-Clapeyron saturation formula. Accordingly, eq. (e4.6) implies that also the
 398 evaporation rate J_W is growing this way, by contrast to eq. (6). This virtual acceleration of the
 399 hydrological cycle is evidently inconsistent with the prediction of Held and Soden (2006). This
 400 parameterisation-caused additional latent heat flux implies a spurious ocean cooling that may

401 contribute to the finding that many numerical climate models tend to underestimate the observed
402 ocean warming (Weller et al. 2022).

403 From eq. (6), the sensitivity of the latent heat flux, LJ_W , with respect to the RH variations is easily
404 estimated. For a mean evaporation rate of 1200 mm per year, the corresponding mass flux is about
405 $J_W \approx 3.8 \times 10^{-5} \text{ kg m}^{-2} \text{ s}^{-1}$ and the related heat flux is $LJ_W \approx 95 \text{ W m}^{-2}$ with respect to the ocean
406 surface area and a specific evaporation enthalpy of $L = 2501 \text{ kJ kg}^{-1}$. At a surface humidity of $\psi_f =$
407 0.8, a value of $D_f(u) \approx 1.87 \times 10^{-4} \text{ kg m}^{-2} \text{ s}^{-1}$ can be concluded for the mass transfer coefficient,
408 and of $LD_f(u) \approx 468 \text{ W m}^{-2}$ for that of latent heat. Then, from

$$409 \quad \Delta(LJ_W) = L \frac{\partial J_W}{\partial \psi_f} \Delta \psi_f = -LD_f(u) \frac{\Delta \psi_f}{\psi_f} \quad (13)$$

410 it follows that an increase by $\Delta \psi_f = 1 \text{ \%rh}$ results in a heat flux reduction by $\Delta(LJ_W) =$
411 5.85 W m^{-2} . So, the currently observed ocean warming (Cheng et al. 2024) of 1.3 W m^{-2} could
412 theoretically be caused already by a minor marine humidity increase of $\Delta \psi_f = 0.2 \text{ \%rh}$, a value far
413 below the present measurement uncertainty between 1 and 5 %rh of relative humidity. The
414 resolution of climate models and observation seems to be insufficient yet to identify the possible role
415 of RH for the unclear explanation of the warming ocean.

416

417 **5 Sea Air as a Two-Phase Composite**

418 Gibbs' (1873) method of using potential functions can be applied to any systems possessing stable
419 thermodynamic equilibria and obeying energy conservation, without being restricted to merely
420 homogeneous or single-phase samples. The intentionally strict mutual consistency of the different
421 TEOS-10 potential functions permits a mathematical description of multi-phase composites such as
422 sea ice, consisting of ice with included brine pockets (Feistel and Hagen 1998, Feistel and Wagner
423 2005), or clouds, where liquid water or ice is floating in saturated humid air (Hellmuth et al. 2021).
424 Another important model is that of *sea air*, a sample consisting of a mass m^{SW} of seawater in
425 thermodynamic equilibrium with a mass m^{AV} of humid air (Feistel et al. 2010d, Feistel and Hellmuth
426 2023). Such a model may serve as a mathematical description for certain thermodynamic properties
427 of ocean-atmosphere interaction.

428 Extensive thermodynamic functions such as Gibbs energy or enthalpy are additive with respect to the
429 two separate phases of the sample. Equilibrium between those parts requires equal temperatures
430 and pressures. For this reason, a Gibbs function of sea air is an appropriate potential for the
431 composite system with $g^{\text{SW}}(S, T, p)$ describing the liquid part and $g^{\text{AV}}(A, T, p)$ the gas part. Let the
432 masses of the substances in the parts be m^{W} of liquid water, m^{S} of dissolved salt, m^{A} of dry air and
433 m^{V} of water vapour. Note that TEOS-10 neglects solubility of dry air constituents in liquid water.
434 From combinations of the partial masses follow the liquid mass, $m^{\text{SW}} = m^{\text{S}} + m^{\text{W}}$, the gas mass,
435 $m^{\text{AV}} = m^{\text{A}} + m^{\text{V}}$, the total mass $m = m^{\text{SW}} + m^{\text{AV}}$, the total water mass $m^{\text{WV}} = m^{\text{W}} + m^{\text{V}}$, the
436 salinity $S = m^{\text{S}}/m^{\text{SW}}$ and the dry-air fraction $A = 1 - q = m^{\text{A}}/m^{\text{AV}}$.

437 The Gibbs energies of the two phases of sea air are additive,

$$438 \quad G^{\text{SA}} = G^{\text{SW}} + G^{\text{AV}} = mg^{\text{SA}}, \quad (14)$$

439 And, accordingly, the Gibbs function of sea air, g^{SA} , may be constructed from that of seawater,
440 $g^{\text{SW}}(S, T, p)$, with a liquid mass fraction of $w^{\text{SW}} = m^{\text{SW}}/m$ and that of humid air, $g^{\text{AV}}(A, T, p)$, with
441 a gaseous mass fraction of $w^{\text{AV}} = m^{\text{AV}}/m = 1 - w^{\text{SW}}$,

$$442 \quad g^{\text{SA}}(S, A, w^{\text{SW}}, T, p) = w^{\text{SW}} g^{\text{SW}}(S, T, p) + (1 - w^{\text{SW}}) g^{\text{AV}}(A, T, p). \quad (15)$$

443 If the two phases are assumed to be at mutual equilibrium, they possess the same temperature,
 444 pressure and chemical potentials, see eq. (B.11) in Appendix B, $\mu_W^{SW} = \mu_V^{AV}$, namely that of water in
 445 seawater,

$$446 \quad \mu_W^{SW}(S, T, p) = g^{SW} - S \left(\frac{\partial g^{SW}}{\partial S} \right)_{T,p}, \quad (15)$$

447 equating that of water vapour in humid air,

$$448 \quad \mu_V^{AV}(A, T, p) = g^{AV} - A \left(\frac{\partial g^{AV}}{\partial A} \right)_{T,p}. \quad (16)$$

449

450 *5.1 Sea Air as a Model for Latent Heat of Evaporation*

451 Water evaporated from the ocean surface drives the climate system. “The by far largest part of heat
 452 conveyed to the air is in the form of latent heat during subsequent condensation along with cloud
 453 formation. The heat budget over the sea is mainly controlled by the latent heat released to the air”
 454 (Albrecht 1940). It is the “*heat source for a gigantic steam engine*”, as Heinrich Hertz had put it in his
 455 1885 inaugural lecture at Karlsruhe (Mulligan and Hertz 1997). The latent heat of evaporation of pure
 456 liquid water into pure water vapour is numerically well known from experiments (IAPWS SR1-86
 457 1992, Harvey 1998, Wagner and Pruß 2002). Slightly differing values are reported in various
 458 textbooks on hydrology (Debski 1966: p. 332), meteorology (Linke and Baur 1970) or geophysics (Gill
 459 1982, Kraus and Businger 1994). TEOS-10, however, permits the computation of evaporation
 460 properties from seawater into humid air, based on the first-time availability of standard equations
 461 for enthalpies and chemical potentials of those non-ideal mixtures.

462

463 Fig. 8: Conceptual thermodynamic “sea air” model of ocean-atmosphere interaction as a two-phase
 464 composite of seawater and humid air

465

466 If an infinitesimal amount of water is transferred from the liquid to the gas phase (Fig. 8), while
 467 temperature and pressure remain at their equilibrium values, and the total masses of salt, m^S , dry
 468 air, m^A , and water, m^{WV} , are not affected, the isobaric-isothermal latent heat of evaporation may be
 469 defined by

$$470 \quad L^{SA} \equiv \left(\frac{\partial H^{SA}}{\partial m^V} \right)_{T,p,m^S,m^A,m^{WV}}. \quad (17)$$

471 This latent heat accounts for the loss of total heat of the sea-air sample associated with the loss of
 472 liquid water and equal gain of water vapour,

$$473 \quad \frac{\partial m^V}{\partial T} = -\frac{\partial m^W}{\partial T}. \quad (18)$$

474 Here, H^{SA} is the enthalpy of sea air, available from the Gibbs function (15) through the sum

$$475 \quad H^{SA} \equiv m^{SW}h^{SW} + m^{AV}h^{AV}. \quad (19)$$

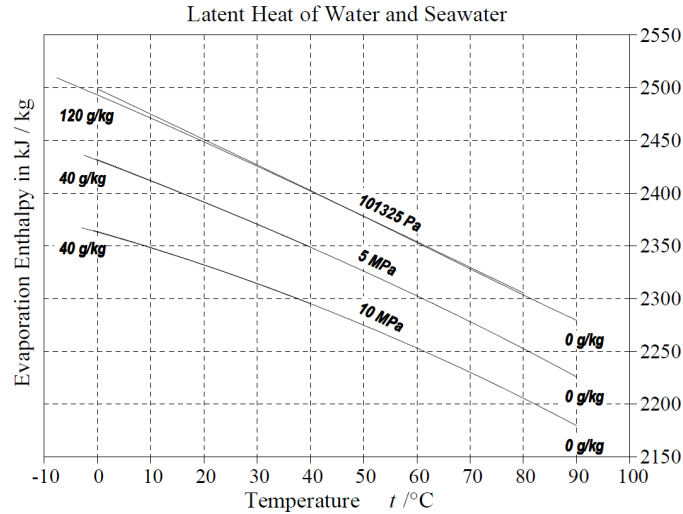

476 Here, the specific enthalpies of seawater,

$$477 \quad h^{SW} = g^{SW} - T \left(\frac{\partial g^{SW}}{\partial T} \right)_{S,p}, \quad (20)$$

478 and of humid air,

$$479 \quad h^{AV} = g^{AV} - T \left(\frac{\partial g^{AV}}{\partial T} \right)_{A,p}, \quad (21)$$

480 are defined in terms of the related Gibbs functions.

481

482 Fig. 9: Evaporation enthalpy, eq. (23), of seawater in equilibrium with humid air at different
 483 temperatures, pressures and salinities. The dependence on salinity is very weak; graphically, the
 484 related curves are hardly distinguishable. The nonlinear dependence on temperature is more
 485 pronounced at elevated pressures. Figure from Feistel et al. (2010a: p. 105)

486

487 The derivative (17) is carried out in the form

$$488 \quad L^{SA} = -h^{SW} - m^{SW} \left(\frac{\partial h^{SW}}{\partial S} \right)_{T,p} \left(\frac{\partial S}{\partial m^V} \right)_{m^S, m^{WV}} + h^{AV} + m^{AV} \left(\frac{\partial h^{AV}}{\partial A} \right)_{T,p} \left(\frac{\partial A}{\partial m^V} \right)_{m^A}, \quad (22)$$

489 which results in the TEOS-10 latent-heat equation (Feistel et al. 2010a, Feistel and Hellmuth 2023),

$$490 \quad L^{SA} = h^{AV} - A \left(\frac{\partial h^{AV}}{\partial A} \right)_{T,p} - h^{SW} + S \left(\frac{\partial h^{SW}}{\partial S} \right)_{T,p}, \quad (23)$$

491 with typical values shown in Fig. 9. If seawater is in mutual equilibrium with humid air at given
492 temperature and pressure, salinity and humidity of the parts of sea air satisfy the condition $\mu_{\text{W}}^{\text{SW}} =$
493 $\mu_{\text{V}}^{\text{AV}}$, given by eqs. (15) and (16),

$$494 \quad \Delta\mu \equiv g^{\text{SW}} - S \left(\frac{\partial g^{\text{SW}}}{\partial S} \right)_{T,p} - g^{\text{AV}} + A \left(\frac{\partial g^{\text{AV}}}{\partial A} \right)_{T,p} = 0 \quad (24)$$

495 At given masses of salt, m^{S} , of dry air, m^{A} , and of total water, $m^{\text{WV}} = m^{\text{W}} + m^{\text{V}}$, eq. (24) controls
496 the value of either m^{W} or m^{V} , and this way also of S and A as functions of T , p , m^{S} , m^{A} and m^{WV} .
497 Related numerical solutions are readily implemented in the TEOS-10 SIA library; the latent heat of
498 sea air can be computed by calling the function `sea_air_enthalpy_evap_si()`, see Wright et al.
499 (2010).

500 Latent heat of eq. (23) is valid regardless of the equilibrium condition, eq. (24), is satisfied or not. The
501 non-equilibrium case is considered separately in Section 5.3.

502

503 *5.2 Sea Air as a Model of Sea Spray*

504 As a special form of air-sea interaction, sea spray is typically ejected from the crest of a breaking
505 wave, which may happen all along oceanic coasts but also wherever whitecaps are produced from
506 swell or stormy sea state, see Fig. 10. In contrast to fresh-water haze, droplets of sea spray cannot
507 completely evaporate for the salt they contain, and rather develop into a floating persistent Köhler
508 (1936) equilibrium between droplet size, droplet salinity and ambient relative fugacity. This
509 equilibrium can be described by the TEOS-10 model of sea air if the additional Kelvin pressure caused
510 by the surface tension is allowed for.

511

512 Fig. 10: Sea spray ejection from a breaking wave crest of Atlantic swell. Photo taken at Cabo Trafalgar
513 in March 2011.

514

515 In the infrared spectral range, sea spray as well as other aerosols (Carlon 1970, 1980) may be
516 considered as a black absorber and emitter of thermal radiation. The resulting “gray atmosphere” is a
517 conveniently simple conceptual model for the long-wave radiative effects of dust or haze in the

518 climate system (Emden 1913). When heated from below, as in the case of the clear-sky marine
519 troposphere, a theoretical finding is that the thermally stratified gray troposphere exhibits a special
520 critical value of the isobaric heat capacity at $c_p = 4R$ (Pierrehumbert 2010: p. 201), R being the
521 molar gas constant. Vertical stability may be lost at $c_p > 4R$ and turbulent mixing is expected to
522 commence (Feistel 2011: eq. 58 therein). Such a kinetic phase transition could substantially modify
523 the thermal radiation balance between troposphere and ocean surface.

524 The terrestrial atmosphere is dominated by the two-atomic gases N_2 and O_2 with heat capacities
525 about $3.5 R$ which prevent the putative radiative vertical instability to occur. This situation may
526 change, however, in the presence of haze or sea spray. To investigate this effect theoretically, in this
527 section a TEOS-10 equation for the heat capacity of equilibrium sea air is derived from the definition

$$528 \quad c_p^{SA} \equiv \frac{1}{m} \left(\frac{\partial H^{SA}}{\partial T} \right)_{p,m^S,m^A,m^{WV}} \quad (25)$$

529 The enthalpy of sea air is given by eq. (19). Taking into account water conservation upon
530 evaporation, $m^{WV} = \text{const}$, that is,

$$531 \quad \frac{\partial m^V}{\partial T} = - \frac{\partial m^W}{\partial T}, \quad (26)$$

532 and of eq. (23), the isobaric heat capacity of sea air is concluded to be

$$533 \quad c_p^{SA} = w^{SW} c_p^{SW} + w^{AV} c_p^{AV} + L^{SA} \frac{1}{m} \frac{\partial m^V}{\partial T}. \quad (27)$$

534 To the additive contributions of the partial heat capacities of the liquid and the gas part, there
535 appears the latent heat of the water mass that evaporates from the liquid as vapour. This
536 evaporation rate is governed by the mutual equilibrium between seawater and humid air.

537 During the temperature change, sea-air equilibrium, eq. (24), is assumed to be maintained by water
538 transfer between the phases, changing S and A along with T ,

$$539 \quad \left(\frac{\partial \Delta \mu}{\partial T} \right)_{p,m^S,m^A,m^{WV}} = 0. \quad (28)$$

540 Carrying out the derivative, this condition reads

$$541 \quad \left(\frac{\partial g^{SW}}{\partial T} \right)_{S,p} - S \left(\frac{\partial^2 g^{SW}}{\partial S \partial T} \right)_p - S \left(\frac{\partial^2 g^{SW}}{\partial S^2} \right)_{T,p} \left(\frac{\partial S}{\partial T} \right)_{m^S} \\ 542 \quad = \left(\frac{\partial g^{AV}}{\partial T} \right)_{A,p} - A \left(\frac{\partial^2 g^{AV}}{\partial A \partial T} \right)_p - A \left(\frac{\partial^2 g^{AV}}{\partial A^2} \right)_{T,p} \left(\frac{\partial A}{\partial T} \right)_{m^A}. \quad (29)$$

543 On the other hand, from combining eq. (23) with eq. (24) it follows that the latent heat may be
544 expressed by,

$$545 \quad L^{SA} = T \left\{ \left(\frac{\partial g^{SW}}{\partial T} \right)_{S,p} - S \left(\frac{\partial^2 g^{SW}}{\partial S \partial T} \right)_p - \left(\frac{\partial g^{AV}}{\partial T} \right)_{A,p} + A \left(\frac{\partial^2 g^{AV}}{\partial A \partial T} \right)_p \right\}, \quad (30)$$

546 so that eq. (29) may be written as

$$547 \quad L^{SA} = T \left\{ S \left(\frac{\partial^2 g^{SW}}{\partial S^2} \right)_{T,p} \left(\frac{\partial S}{\partial T} \right)_{m^S} - A \left(\frac{\partial^2 g^{AV}}{\partial A^2} \right)_{T,p} \left(\frac{\partial A}{\partial T} \right)_{m^A} \right\}. \quad (31)$$

548 Further, the total water mass balance, eq. (26), implies that

$$549 \quad \left(\frac{\partial S}{\partial T} \right)_{m^S} = \left(\frac{\partial S}{\partial m^W} \right)_{m^S} \frac{\partial m^W}{\partial T} = \frac{S}{m^{SW}} \frac{\partial m^V}{\partial T}, \quad (32)$$

550 and similarly,

$$551 \left(\frac{\partial A}{\partial T}\right)_{m^A} = \left(\frac{\partial A}{\partial m^V}\right)_{m^A} \frac{\partial m^V}{\partial T} = -\frac{A}{m^{AV}} \frac{\partial m^V}{\partial T}. \quad (33)$$

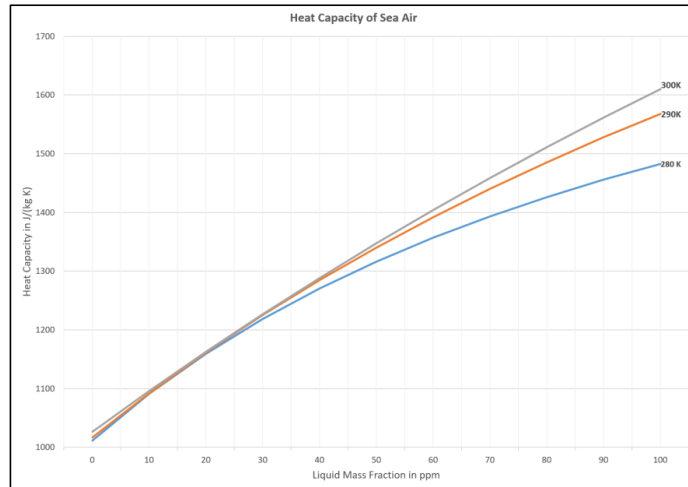

552 Inserting those expressions into eq. (31), the equation for the isobaric evaporation rate of sea air is

$$553 \frac{\partial m^V}{\partial T} = \frac{L^{\text{evap}}}{T} \left\{ \frac{S^2}{m^{\text{SW}}} \left(\frac{\partial^2 g^{\text{SW}}}{\partial S^2}\right)_{T,p} + \frac{A^2}{m^{AV}} \left(\frac{\partial^2 g^{AV}}{\partial A^2}\right)_{T,p} \right\}^{-1}. \quad (34)$$

554 Together with eq. (34), the desired formula for the isobaric heat capacity (27) of sea air finally
555 becomes (Feistel et al. 2010a: eq. 6.22 therein),

$$556 c_p^{\text{SA}} = w^{\text{SW}} c_p^{\text{SW}} + (1 - w^{\text{SW}}) c_p^{\text{AV}} + \frac{(L^{\text{SA}})^2}{T} \left\{ \frac{S^2}{w^{\text{SW}}} \left(\frac{\partial^2 g^{\text{SW}}}{\partial S^2}\right)_{T,p} + \frac{A^2}{(1-w^{\text{SW}})} \left(\frac{\partial^2 g^{AV}}{\partial A^2}\right)_{T,p} \right\}^{-1}. \quad (35)$$

557 Of the *liquid water content*, expressed in form of the liquid mass fraction, w^{SW} , realistic values may
558 typically range between 10^{-6} and 10^{-4} in the troposphere. Growing along with this fraction, related
559 heat capacities of sea air, eq. (35), may substantially exceed that of liquid-free humid air, c_p^{AV} , see
560 Fig. 11.

561

562 Fig. 11: TEOS-10 values for the isobaric specific heat capacity, eq. (35), of sea air at atmospheric
563 pressure and sea-spray standard-ocean salinity, $S = 35.16504 \text{ g kg}^{-1}$, at temperatures of 280 K (lower
564 curve), 290 K (middle curve) and 300 K (upper curve) as functions of the liquid mass fraction, w^{SW} ,
565 up to 100 ppm.

566

567 5.3 Sea Air as a Model for Irreversible Evaporation

568 The climate system functions far from thermodynamic equilibrium, permanently producing and
569 exporting entropy at an average rate of $1 \text{ W m}^{-2} \text{ K}^{-1}$ per global surface area (Ebeling and Feistel 1982,
570 Feistel and Ebeling 2011). By contrast, TEOS-10 is a mathematical description of equilibrium
571 properties (Appendix B). The latter is applicable to states away from thermodynamic equilibrium
572 under the assumption of *local equilibrium* as introduced by Ilya Prigogine (1947, 1978). This
573 assumption means that spatially extended substances such as ocean or atmosphere consist of
574 sufficiently small volume elements that may reasonably be described as macroscopic equilibrium

575 states, homogeneous in temperature, pressure and chemical potentials. TEOS-10 thermodynamic
576 potentials can be used to describe those local states.

577 By definition, if a volume at equilibrium is divided into partial volumes, each of those parts is at
578 equilibrium itself, and each pair of those is at mutual equilibrium also. The combination of several
579 local-equilibrium elements forms a non-equilibrium state if pairs of elements exist that are out of
580 mutual equilibrium. Extensive properties such as mass, energy, entropy or enthalpy can be added up
581 to give correct values of the entire system. When exchange processes between those elements
582 occur, gains and losses of masses, energies or enthalpies are mutually balanced by conservation laws,
583 however, this is not the case for entropy.

584 A tutorial case of a local equilibrium system may be the model of sea air (Feistel and Hellmuth 2024a)
585 depicted in Fig. 8. It consists of a mass $m^{SW} = m^S + m^W$ of seawater in contact with a mass $m^{AV} =$
586 $m^A + m^A$ of humid air. Both fluids are assumed to be at internal equilibrium themselves but not
587 necessarily in mutual equilibrium with one another. This is a natural geophysical situation – marine
588 RH has typical values of 80 %rh while the equilibrium of humid air with seawater, eq. (24), is
589 established at about 98 %rh. For simplicity, let all parts have equal temperatures and pressures.

590 If evaporation takes place, the partial water masses involved will change by a mass flux across the
591 sea surface,

$$592 \quad J_m \equiv \frac{dm^{AV}}{dt} = \frac{dm^V}{dt} = -\frac{dm^{SW}}{dt} = -\frac{dm^W}{dt}. \quad (36)$$

593 The change of the total enthalpy of the sea-air sample is available from eqs. (17) and (23),

$$594 \quad \frac{dH^{SA}}{dt} = \left(\frac{\partial H^{SA}}{\partial m^V} \right)_{T,p,m^S,m^A,m^{WV}} \frac{dm^V}{dt} = L^{SA} J_m. \quad (37)$$

595 This expression of energy conservation, the 1st law of thermodynamics, is similarly valid for
596 equilibrium and non-equilibrium conditions of the sample. For comparison, of the total entropy
597 defined by,

$$598 \quad N^{SA} \equiv m^{SW} \eta^{SW} + m^{AV} \eta^{AV}, \quad (38)$$

599 the change is given by

$$600 \quad \frac{dN^{SA}}{dt} = \left(\frac{\partial N^{SA}}{\partial m^V} \right)_{T,p,m^S,m^A,m^{WV}} \frac{dm^V}{dt}. \quad (39)$$

601 In terms of its two parts, eq. (38), this change takes the form,

$$602 \quad \frac{dN^{SA}}{dt} = \left[\eta^{AV} - A \left(\frac{\partial \eta^{AV}}{\partial A} \right)_{T,p} - \eta^{SW} + S \left(\frac{\partial \eta^{SW}}{\partial S} \right)_{T,p} \right] J_m. \quad (40)$$

603 Making use of their local equilibria, specific entropy of each part can be expressed by the difference,
604 eq. (B.6),

$$605 \quad \eta = \frac{h-g}{T}, \quad (41)$$

606 between specific enthalpy, h , and specific Gibbs energy, g , so that the entropy change becomes

$$607 \quad T \frac{dN^{SA}}{dt} = (L^{SA} + \Delta\mu) J_m. \quad (42)$$

608 Here, the latent heat, L^{SA} , is given by eq. (23), and the distance from mutual equilibrium, $\Delta\mu$, by eq.
609 (24).

610 The first term,

$$611 \quad T \frac{d_e N^{SA}}{dt} \equiv L^{SA} J_m, \quad (43)$$

612 is the *external* entropy change (subscript e) in the form of the heat flux required to maintain the
613 sample's temperature, compensating the storage of latent heat by emitting water vapour.

614 The second term,

$$615 \quad T \frac{d_i N^{SA}}{dt} \equiv J_m \Delta\mu. \quad (44)$$

616 is the *internal* entropy change (subscript i), or *entropy production*, of the non-equilibrium sea-air
617 sample. It represents the additional entropy gain of humid air compared to the entropy loss of
618 seawater. This production happens at the air-sea interface and disappears as soon as mutual
619 equilibrium, $\Delta\mu = 0$, is approached.

620 It is important to be aware that the external part, $\frac{d_e N^{SA}}{dt}$, *always* constitutes a contribution to the
621 system's energy balance while, by contrast, the internal part, $\frac{d_i N^{SA}}{dt}$, is *never* any such contribution.
622 The irreversible production of entropy is an internal conversion or redistribution of energy rather
623 than a change of it. This implies that irreversible processes violate Gibbs' fundamental equation (B.8)
624 in the sense that

$$625 \quad \frac{dH^{SA}}{dt} = -T \frac{d_e N^{SA}}{dt} + V^{SA} \frac{dp}{dt} + \sum_i \mu_i \frac{dm_i}{dt} > -T \frac{dN^{SA}}{dt} + V^{SA} \frac{dp}{dt} + \sum_i \mu_i \frac{dm_i}{dt}, \quad (45)$$

626 even though each of its local-equilibrium elements strictly satisfies the related fundamental equation
627 (B.13), valid for reversible processes only,

$$628 \quad dh = -T d\eta + v dp + \sum_{i=1}^{n-1} (\mu_i - \mu_0) dw_i. \quad (46)$$

629 Entropy production appears wherever a flux is passing its driving gradient. Near equilibrium, this flux
630 is proportional to its driving force (Glandsdorff and Prigogine 1971, Landau and Lifschitz 1974, Kraus
631 and Businger 1994, Feistel and Hellmuth 2024a), usually termed *Onsager force*. For example, the
632 evaporation mass flux of water, eq. (6),

$$633 \quad J_m = C \Delta\mu \quad (47)$$

634 may be assumed as being proportional to the difference between the chemical potentials of water
635 across the air-sea interface. The related *Dalton equation* (6) was discussed in Section 4. The
636 associated entropy production, eq. (44), obeys the 2nd law of thermodynamics by the inequality

$$637 \quad \frac{d_i N^{SA}}{dt} = C (\Delta\mu)^2 \geq 0, \quad (48)$$

638 while the total entropy change, eq. (42) may possess any sign. In other words, the 2nd law forbids that
639 *Onsager fluxes* may be directed against their causing Onsager forces.

640 Processes accompanied by entropy production are termed *irreversible* ones, since entropy once
641 created may never be destroyed again. Related processes cannot be reversed unless lasting changes
642 are left behind in the external world. By contrast, processes which transform an equilibrium state
643 into another equilibrium state may *reversibly* be performed without producing entropy. Entropy
644 production is possible only under non-equilibrium conditions.

645 Under typical marine circumstances, the entropy production density of ocean evaporation can be
646 estimated to about $4 \text{ mW K}^{-1} \text{ m}^{-2}$, contributing roughly 0.4 % to the global entropy production
647 (Feistel and Ebeling 2011, Feistel and Hellmuth 2024a).

648

649 **6 Cloudiness and Ocean Warming**

650 On the long-term average, cloudiness is particularly strong in the low-pressure belts of the global
651 tropospheric circulation, where air is ascending and its humidity is condensing, see Fig. 12. Except for
652 the equatorial zone, those spatial cloudiness pattern correlate visibly with those of recent ocean
653 warming, compare Fig. 1. It is a plausible working hypothesis that this correlation could also indicate
654 a causal relation between the two phenomena. However, such correlations imply hen-and-egg
655 problems (Rapp 2014): putative causality relations between those trends cannot be derived from
656 observation but only be concluded from reliable prediction models (Feistel 2023). May the observed
657 systematic reduction of global cloudiness (Fasullo and Trenberth 2012) actually be responsible for
658 the currently recorded excessive ocean warming (You 2024)? Unfortunately, and somewhat
659 surprisingly, this assumption can apparently not be underpinned yet by closer investigation. Some
660 related issues will be discussed in this section.

661

662 Fig. 12: Global distribution of cloudiness July 2002 – April 2015 (Allen and Ward 2015). Image
663 reproduction permitted by NASA Copyright.

664 *6.1 Cloudiness Trend*

665 Global cloud-covered surface area fraction C has systematically been reducing by about 6 % per
666 century, see Fig. 13, from $C \approx 67.5 \%$ in 1980 to $C \approx 65 \%$ in 2022 (Foster et al. 2023, Phillips and
667 Foster 2023). Observed cloudiness values depend strongly on the way clouds are defined (Spänkuch
668 et al. 2022) and on the measurement technology applied. For example, Rapp (2014: Fig. 6.20)
669 reported a decrease in cloudiness in 30 years from 70 % in 1983 down to 63.5 % in, likely, 2013. This
670 reduction rate of more than 20 % per century is three times as fast as that given in Fig. 13 and may
671 result from different observation techniques.

672

673 Fig. 13: Dots: satellite-derived global mean cloud area fractions 1980-2022 in percent. Data from
674 Foster et al. (2023). Dashed line: present cloudiness is 65 % with a climatological linear shrinking
675 trend of -6.2% per century.

676

677 Assuming that this shrinking occurred in a similar way above both land and sea, the ocean is
678 expected to receive increasingly more solar irradiation. This phenomenon is known as the *short-wave*
679 *cloud radiative effect* (SW CRE), see Fig. 14.

680

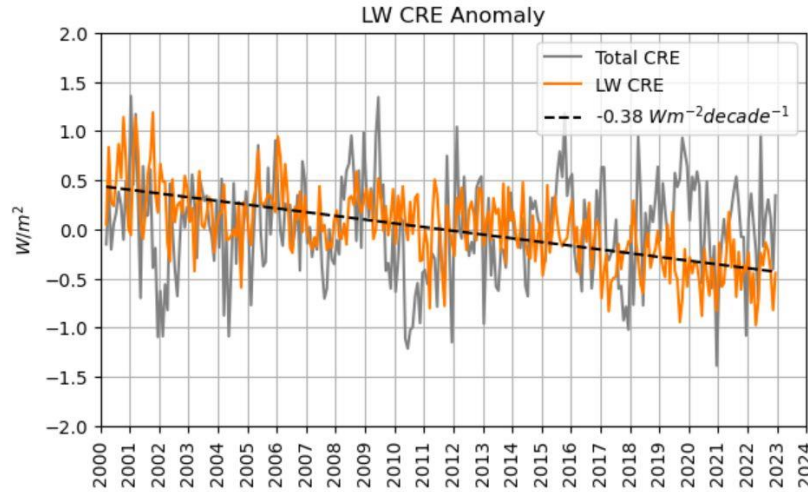

681 Fig. 14: Short-wave cloud radiative effect (SW CRE) of increasing solar irradiation. Image kindly
682 provided by Coda Phillips (priv. comm.), with minor correction compared to the original publication
683 (Phillips and Foster 2023). Total CRE is the net effect of SW and LW CRE, see Fig. 15.

684

685 On the other hand, clouds are opaque with respect to oceanic upward thermal radiation and emit
686 themselves downward infrared radiation. This phenomenon is known as the *long-wave cloud*
687 *radiative effect* (LW CRE), see Fig. 15. Radiation models show that on the global average these two
688 effects cancel each other almost completely up to minor rest of $-1 mW m^{-2} yr^{-1}$, so that the
689 continuously shrinking cloudiness may be assumed to have practically no net effect on the ocean's
690 radiation balance (Phillips and Foster 2023, Feistel and Hellmuth 2024b). However, more detailed

691 investigations in the future may reveal more rigorous results for the ocean than this simplified
692 picture.

693

694 Fig. 15: Long-wave cloud radiative effect (LW CRE) of decreasing net thermal radiation. Image kindly
695 provided by Coda Phillips (priv. comm.), with minor correction compared to the original publication
696 (Phillips and Foster 2023). Total CRE is the net effect of SW and LW CRE, see Fig. 14.

697

698 6.1 Cumulus Clouds

699 Cumulus clouds are often formed in the course of diurnal convection by isentropic uplift of humid air
700 parcels from the sea surface to the condensation level, mostly located at low heights between 200
701 and 500 m. This process permits a thermodynamic description of such clouds (Romps 2014) by
702 calculating the *lifted condensation level* (LCL) as the cumulus cloud base. As the first such
703 international geophysical standard, TEOS-10 provides explicit equations for entropy, enthalpy and
704 chemical potentials of humid air which may be used to derive reference equations and values of the
705 LCL (Feistel and Hellmuth 2024b).

706 At the sea surface pressure, p_0 , the air parcel may possess the temperature T_0 and the relative
707 fugacity ψ_f , which is a real-gas definition of relative humidity (Feistel and Lovell-Smith 2017) in terms
708 of the chemical potential of water vapour in humid air, μ_V^{AV} , and that of liquid water, μ_W ,

$$709 R_W T_0 \ln \psi_f = \mu_V^{AV}(A, T_0, p_0) - \mu_W(T_0, p_0). \quad (49)$$

710 Here, $R_W = 461.523 \text{ J kg}^{-1} \text{ K}^{-1}$ is the specific gas constant of water, and $A = 1 - q$ is the dry-air
711 mass fraction of the parcel, to be determined from ψ_f by this condition.

712 At the LCL, the parcel is saturated at $\psi_f = 1$, i.e.,

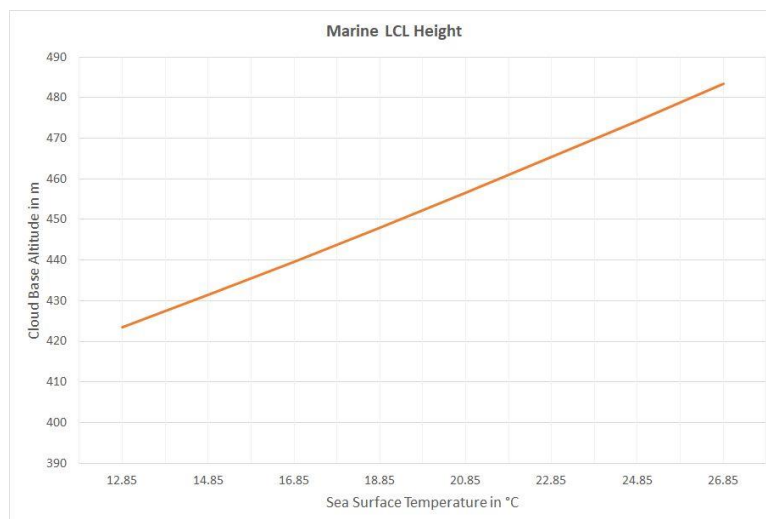

$$713 0 = \mu_V^{AV}(A, T_{LCL}, p_{LCL}) - \mu_W(T_{LCL}, p_{LCL}). \quad (50)$$

714 During uplift, A is assumed to remain constant, as well as the parcel's entropy, η^{AV} ,

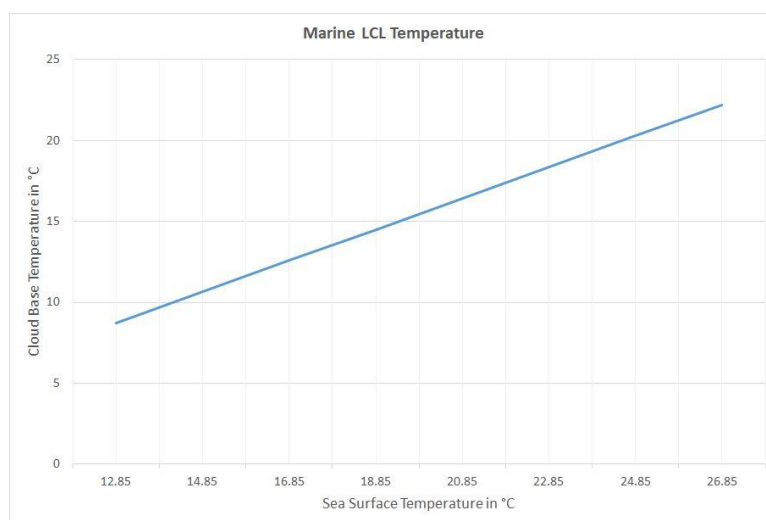

$$715 \eta^{AV}(A, T_0, p_0) = \eta^{AV}(A, T_{LCL}, p_{LCL}). \quad (51)$$

716

717

718

719 Fig. 16: As a function of typical low-latitude sea-surface temperatures, LCL height (top) and LCL
 720 temperature (bottom) are computed from the TEOS-10 equations (49) – (52) at a typical marine
 721 surface RH of 80 %rh.

722

723 Finally, the LCL altitude, z_{LCL} , above sea level follows from the isentropic integral of the hydrostatic
 724 equation in terms of the enthalpy, h^{AV} , of humid air,

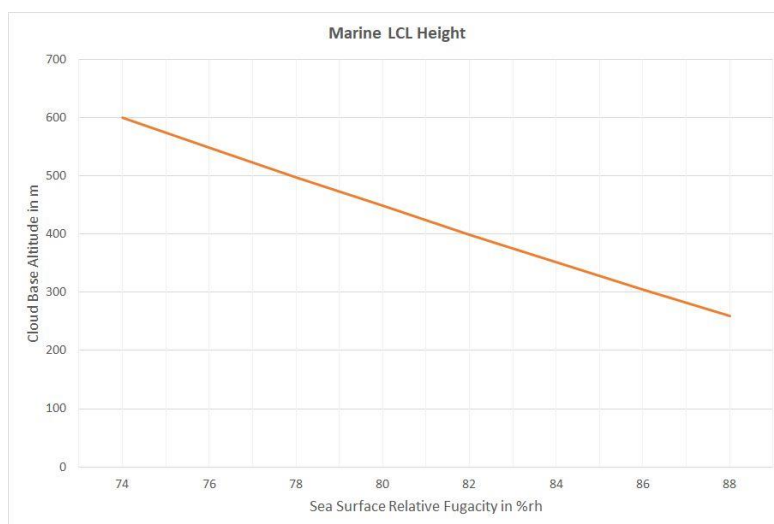

$$725 \quad z_{LCL} = \frac{1}{g_E} [h^{AV}(A, \eta^{AV}, p_0) - h^{AV}(A, \eta^{AV}, p_{LCL})]. \quad (52)$$

726 The gravity acceleration is $g_E = 9.81 \text{ m s}^{-2}$. The functions μ_V^{AV} , η^{AV} , h^{AV} and μ_W can be expressed
 727 by partial derivatives of the TEOS-10 thermodynamic potentials of humid air and liquid water, and
 728 are numerically available from the *Sea-Ice-Air (SIA) library* (Feistel et al. 2010d, Wright et al. 2010).

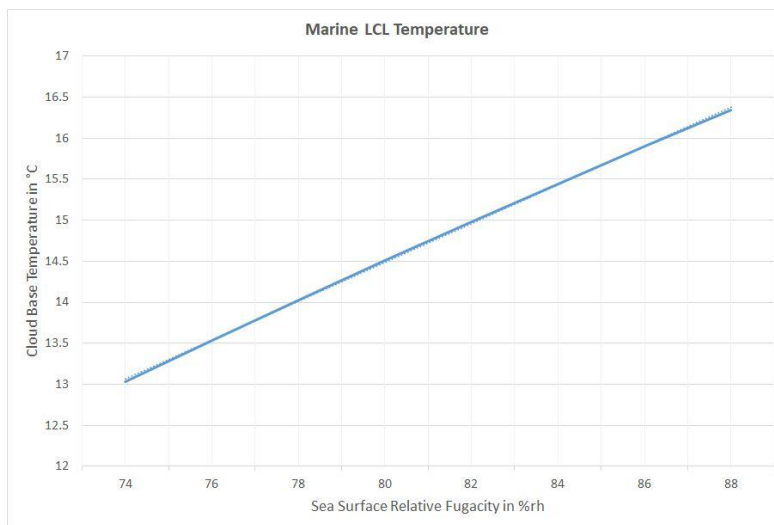

729 Solving eqs. (49) – (52) numerically, the LCL properties ($A, T_{LCL}, p_{LCL}, z_{LCL}$) are obtained from the
730 given surface properties, (ψ_f, T_0, p_0) .

731 As solutions of eqs. (49) – (52), height and base temperature of marine cumulus clouds, as a function
732 of the sea-surface temperature T_0 at a sea-surface relative fugacity of $\psi_f = 80\%$ rh, are displayed in
733 Fig. 16. Similarly, height and base temperature, as a function of the sea-surface relative fugacity of
734 ψ_f at a sea-surface temperature $T_0 = 292$ K, close to the current global mean SST, are displayed in
735 Fig. 17.

736

737

738 Fig. 17: As a function of typical marine RH values, LCL height (top) and LCL temperature (bottom) are
739 computed from the TEOS-10 equations (49) – (52) at a sea surface temperature of 292 K, close to the
740 current global mean SST of 18.8 °C, see Fig. 18.

741

742

743 Table 1: LCL cloud-base temperatures, T_{LCL} , pressures, p_{LCL} , and heights, z_{LCL} , as functions of the
 744 SST, T_0 , at marine surface relative fugacity of $\psi_f = 80\%$ rh, computed from TEOS-10 eqs. (49) – (52),
 745 as well as climatic LCL sensitivities, α , β , γ , eq. (53), with respect to increasing SST (Feistel and
 746 Hellmuth 2024). The row printed in bold approximates the current global mean SST, see Fig. 18.

T_0 K	T_{LCL} K	p_{LCL} hPa	z_{LCL} m	α % K ⁻¹	β K K ⁻¹	γ hPa K ⁻¹
286	281.883	963.093	423.468	-0.0483	0.9634	-0.2742
288	283.810	962.542	431.481	-0.0542	0.9629	-0.2773
290	285.735	961.984	439.660	-0.0608	0.9624	-0.2806

747

748

749

750 Fig. 18: Estimated increase 1957 – 2023 of global annual mean sea-surface temperatures (source:
 751 Cheng et al. 2024). The linear trend (red) is $t/^\circ\text{C} \approx 18 + 0.01 \times (yr - 1961)$. The quadratic trend
 752 curve (blue) suggests an acceleration of warming.

753

754 Global mean sea-surface temperature has risen from about 17.9 °C in 1956 to 18.8 °C in 2023 (Cheng
 755 et al. 2024), see Fig. 18. This pronounced climatic trend is expected to let the cumulus cloud base lift
 756 up while at the same time warming it, see Fig. 16, but less than the SST itself is increasing. The
 757 related climatic sensitivities possess complicated dependencies but may directly be derived by taking
 758 the related derivatives

$$759 \quad \alpha \equiv \left(\frac{\partial A}{\partial T_0} \right)_{p_0, \psi_f} = - \left(\frac{\partial q}{\partial T_0} \right)_{p_0, \psi_f}, \quad \beta \equiv \left(\frac{\partial T_{LCL}}{\partial T_0} \right)_{p_0, \psi_f} \quad \text{and} \quad \gamma \equiv \left(\frac{\partial p_{LCL}}{\partial T_0} \right)_{p_0, \psi_f}, \quad (53)$$

760 of the TEOS-10 LCL equations (49) – (52) with respect to the surface temperature while keeping
 761 surface RH fixed (Feistel and Hellmuth 2024). Selected results for those sensitivities are given in Table
 762 1 relative to 1 °C rise of SST, similar to that in the past 70 years (Fig. 16). Here, $\alpha \approx -0.07\%$ K⁻¹

763 describes the rate of increase of specific humidity at the sea surface, often dubbed the “Clausius-
764 Clapeyron effect”. The value of $\beta \approx 0.96$ indicates that the cumulus cloud base warms up slower
765 that the ocean by about 4 %, and $\gamma \approx -0.28 \text{ hPa K}^{-1}$ is the LCL pressure lowering caused by ocean
766 warming, corresponding to ascending clouds. The value $\beta < 1$ implies that the thermal downward
767 radiation from the cloud base does not keep pace with the ocean upward radiation, so that the net
768 climatic feedback of cumulus clouds is negative and acts against ocean warming. These clouds do not
769 provide a physical explanation for the observed enhanced ocean warming.

770

771 *6.2 Stratocumulus and Other Clouds*

772 The dominating cloud type over the ocean is stratocumulus (Eastman et al. 2011). “They are common
773 over the cooler regions of subtropical and midlatitude oceans where their coverage can exceed 50%
774 in the annual mean” (Wood 2012: p. 2373) with a typical thickness about 320 m and “a tendency for
775 thicker clouds (median 420 m) in mid- and high latitudes” (Wood 2012: p. 2378). “Stratocumuli tend
776 to form under statically stable lower-tropospheric conditions” (Wood 2012: p. 2374). On the annual
777 average, stratocumulus is particularly frequent (up to 60 % coverage) at the subtropical coastal
778 upwelling regions such as the cold Benguela, Humboldt and California Currents (Wood 2012: Fig. 4a,
779 Muhlbauer et al. 2014: Fig. 2). However, in those areas there is no obvious correlation of cloud cover
780 with ocean warming (Fig. 1). Stratocumulus also forms large cloud cover (about 20 % coverage) in the
781 boreal and austral west-wind bands (Wood 2012: Fig. 4a) where the ocean is strongly warming up
782 (Fig. 1).

783 “Only small changes in the coverage and thickness of stratocumulus clouds are required to produce a
784 radiative effect comparable to those associated with increasing greenhouse gases” (Wood 2012: p.
785 2374). “Low-cloud feedbacks are also a leading cause of uncertainty in future climate prediction
786 because even small changes in cloud coverage and thickness have a major impact on the radiation
787 budget” (Wood 2012: p. 2373). Marine stratocumulus cloud feedback is still a major challenge and
788 source of uncertainty of climate models (Hirota et al. 2021). However, “similar to other low-cloud
789 types in the marine boundary layer, the impact of stratocumulus clouds on the outgoing longwave
790 radiation is marginal due to the lack of contrast between the temperature of stratocumulus cloud
791 tops and the temperature of the sea surface over which they form. Thus, the net radiative effect of
792 stratocumulus clouds is primarily controlled by factors influencing their shortwave cloud forcing such
793 as the cloud albedo and the cloud coverage” (Muhlbauer et al. 2014: p. 6695).

794 Following this argumentation and assuming that the short-wave cloud effect of stratocumuli on the
795 ocean radiation balance by far outweighs their long-wave effects, then the short-wave warming
796 effect (Fig. 14) of decreasing cloudiness may dominate over the long-wave cooling (Fig. 15). Possibly,
797 this could make stratocumulus a potential candidate for causing the unclear recent ocean warming.

798 Similarly, in the diurnal cycle, short wave effects (Fig. 14) have an impact at daytime only, while long
799 wave effects (Fig. 15) are present all 24 hours. Regionally, where in spring the days get longer, and
800 the heavy cloudiness of the west-wind belt becomes replaced by fewer subtropical clouds (see Fig.
801 12), the systematic reduction of cloudiness may be expected to produce local excess warming such as
802 near the subtropical fronts (see Fig. 1). Only dedicated future model studies, however, may reliably
803 verify such speculations.

804

805

806

807 **7 Summary**

808 Substantial uncertainties of estimated heat fluxes at the ocean-atmosphere interface, such as the
809 “ocean heat budget closure problem”, prevent reliable model predictions and causal explanations of
810 climate phenomena that may take place within the range of those uncertainties. Among such
811 “surprises” is the currently registered excessive ocean warming, but are, expectedly, also the
812 subsequent consequences of this warming for global weather processes.

813 Intending to reduce model uncertainties of thermal energies and heat fluxes in the climate system
814 associated with the global circulation of water in its different phases and mixtures, the new
815 geophysical thermodynamic standard TEOS-10 had been adopted internationally in 2009 and 2011.
816 Meanwhile, the uptake of TEOS-10 by the scientific community is mainly focussed on ocean
817 modelling, as the related publication metrics are suggesting (Appendix A).

818 TEOS-10 is advanced over previous similar standards and various collections of tailored empirical
819 property equations by (i) its completeness in describing all thermodynamic properties of seawater,
820 humid air and ice, including their entropies, enthalpies and chemical potentials, (ii) its perfect mutual
821 consistency between different phases and mixtures, and (iii) its minimum uncertainty over maximum
822 ranges of validity. Among its particularly favourable fields of application are composite systems with
823 internal phase boundaries such as air sea interaction or cloud formation.

824 In addition to entropies, enthalpies and chemical potentials, TEOS-10 has made available certain new
825 quantities for the description and modelling of climate processes, such as (i) Absolute Salinity of the
826 ocean with a specified Reference Composition, (ii) Conservative Temperature as a measure of
827 Potential Enthalpy of seawater representing a definite heat content, and (iii) Relative Fugacity as the
828 thermodynamic driving force of evaporation, suggesting an improved full-range definition of relative
829 humidity as a substitute for mutually inconsistent and restricted such definitions in practical use in
830 climatology, meteorology and physical chemistry.

831 This paper explains some tutorial examples for the application of TEOS-10 to selected current climate
832 problems. There is (i) the two-phase conceptual model of “sea air” which provides rigorous equations
833 for the latent heat of evaporation, for the heat capacity of humid air including salty aerosols (sea
834 spray), and for the irreversible production of entropy by evaporation into the marine troposphere.
835 There is also (ii) the formation of low marine cumulus clouds by isentropic thermal convection up to
836 their condensation level, and their climatic feedback to surface temperature and humidity
837 concerning their infrared radiation effects.

838 It is currently unclear why and how the ocean warming is intensifying, and when and how the related
839 enormous amount of heat may transfer to the atmosphere. The observed systematic reduction of
840 cloudiness may play an important role in this process, but responsible details and theoretical causes
841 are unknown. Marine surface relative humidity is an important and rather sensitive “control valve”
842 for the supply of the troposphere with latent heat, however, the common assumption of constant
843 relative humidity during climate change lacks rigorous explanation and leaves open the question of
844 its possible trends below the insufficiently high level of observational uncertainty. TEOS-10 may
845 further assist climate modellers to address such issues.

846 Ocean Science has proved a scientifically well-respected, reliable and successful partner journal for
847 the publication of advanced results and methods in oceanography and geophysics. Cooperation with
848 international bodies such as IUGG, UNESCO/IOC, IAPSO, SCOR, IAPWS and BIPM has made the
849 development and international introduction of TEOS-10 possible. The established standing
850 committee JCS remains active with respect to related fundamental problems still to be solved. It is

851 hoped and expected that TEOS-10 may constitute a reliable long-term thermodynamic basis for
852 interdisciplinary climate research.

853

854 **Appendix A: Summary and Metrics of Selected Publications Related to TEOS-10**

855 Between December 2008 and December 2012, supporting the activities of SCOR/IAPSO WG127,
856 *Ocean Science* had published 16 articles open-access in its Special Issue #14, “Thermophysical
857 properties of seawater” (Feistel et al. 2008). From February 2013 on, monthly metrics have been
858 recorded by the journal. Table A1 reports those metrics of the last decade.

859 For comparison, metrics – as far as published elsewhere by 04 April 2024 – of selected TEOS-10
860 articles listed at www.teos-10.org are reported in Table A2.

861 **Table A1:** Metrics of articles in the *Ocean Science* Special Issue #14, “Thermophysical properties of
862 seawater” (Feistel et al. 2008a), from February 2013 till March 2024. “SIA” stands for the TEOS-10
863 Sea-Ice-Air open source code library.

878 **Appendix B: Thermodynamic Potentials**

879 This Appendix provides a short introduction to thermodynamic potentials, supporting the equations
 880 and topics discussed in this article. Alternative presentations from different perspectives are
 881 available from numerous textbooks such as Guggenheim (1949), Margenau and Murphy (1964),
 882 Landau and Lifschitz (1966) or Kittel (1969).

883 A key theoretical tool for the physical investigation of the globally warming climate and the related
 884 energy balances is *thermodynamics*. It is known from experience that there exists a distinguished
 885 state of various ambient substances that is known as a *thermodynamic equilibrium state*. If a sample
 886 of matter is in this state, it may never spontaneously alter its measurable macroscopic properties
 887 unless it becomes disturbed by external contact and exchange of energy or matter with its
 888 surrounding. Typical properties which characterise a particular equilibrium state are the total mass of
 889 a sample, m , its volume, V , its temperature, T , or its pressure, p . Of a given sample, different
 890 equilibrium states may exist that differ in those quantities, but there exists a specific relation
 891 between those variables, known as an *equation of state*, which is characteristic for the given
 892 substance and remains universally valid at any of its possible equilibrium states. The most general
 893 and comprehensive equation of state of a given substance is a *thermodynamic potential* of that
 894 substance.

895 Thermodynamics is a mathematical theory for the construction and exploitation of equations of state
 896 and of properties derived thereof for the prediction or verification of observations or experiments.
 897 Depending on the properties of interest, equations of state may be formulated in various different
 898 mathematical forms. It was discovered by J. Willard Gibbs (1873) that from a suitable thermodynamic
 899 potential all thermodynamic properties of a given substance at any of its equilibrium states can be
 900 derived by appropriate mathematical methods.

901 For theoretical reasons (namely, the statistical so-called *canonical ensemble*), a preferred
 902 thermodynamic potential of a pure substance is its *Helmholtz Energy*, or *Free Energy*, $F(m, T, V)$,
 903 expressed in terms of the sample's mass, m , its temperature und volume. For mixtures, the single
 904 mass must be replaced by the set of partial masses of the species involved. Here, mass is used as a
 905 measure for the amount of substance, rather than particle or mole numbers, for the practical reason
 906 that in oceanography masses are easier measured than moles, and so TEOS-10 is following that
 907 tradition and is a mass-based description. Classical empirical thermodynamics is independent of the
 908 existence and properties of atoms or molecules which presently define the mole (BIPM 2019).

909 To the total energy E of the sample, the Helmholtz energy is related by the Helmholtz Differential
 910 Equation,

911
$$E = F - T \left(\frac{\partial F}{\partial T} \right)_{m,V} \tag{B.1}$$

912 The potential function F is extensive, which means that for instance $F(2 m, T, 2 V) = 2 F(m, T, V)$ is
 913 valid for an equilibrium sample of twice the mass. It follows that the mass-specific Helmholtz
 914 function, $F/m \equiv f(T, \rho)$, depends on two variables only, T and the mass density, $\rho \equiv m/V$, and is

915 mathematically simpler and more convenient than F , which may always be retrieved from a given f
916 by

$$917 \quad F(m, T, V) = m \times f\left(T, \frac{m}{V}\right). \quad (\text{B.2})$$

918 The quantitative description of a substance of interest in the form of a thermodynamic potential such
919 as $f(T, \rho)$ has axiomatic properties. The description is *complete*, i.e., all thermodynamic properties of
920 that substance are available, it is *consistent*, i.e., for any property one and only one result can be
921 derived, and it is *independent*, i.e., no part of this description may be omitted without losing the
922 completeness. It is obvious that such axiomatic properties are very desirable for the description of
923 geophysical substances, however, such thermodynamic potentials are rarely found in the
924 corresponding literature. In particular in climate research which combines results and data from
925 different disciplines, such as meteorology and oceanography, from research carried out all over the
926 globe and over the years by subsequent generations of specialists, international binding standards
927 such as the International System of Units (SI) are required that ensure mutual consistency and
928 metrological comparability of any involved data produced from experiments, observations and
929 models.

930 Gibbs' (1873a) original potential function was (internal) energy, $e = E/m$. It is known that a sample's
931 energy can be increased by compression, $-pdv$, where $v = 1/\rho$ is the specific volume, or by input of
932 heat, $Td\eta$, where $\eta = N/m$ is the specific entropy. As an extensive quantity, entropy introduced by
933 Clausius (1865, 1976) is denoted here by N to avoid confusion with seawater salinity, S . Energy
934 conservation implies that

$$935 \quad de = Td\eta - pdv. \quad (\text{B.3})$$

936 Any such change between different equilibrium states of the same sample takes place along a
937 definite, substance-specific surface $e(\eta, v)$ so that de in eq. (B.3) is mathematically an exact
938 differential and the partial derivatives of e possess the physical meanings that

$$939 \quad T = \left(\frac{\partial e}{\partial \eta}\right)_v, \quad -p = \left(\frac{\partial e}{\partial v}\right)_\eta. \quad (\text{B.4})$$

940 Gibbs (1873b) also demonstrated that for several equilibrium samples in contact with one another, in
941 absence of gravity or accelerated motion, the samples are in mutual equilibrium only if they have
942 equal values of the coefficients T and p of eq. (2.3).

943 In the geophysical practice, the quantities η and v are difficult to measure, in contrast to, say, T or p .
944 Mathematically equivalent to $e(\eta, v)$, thermodynamic potentials in terms of the other three possible
945 pairs of independent variables are formally obtained from so-called Legendre transforms (Alberty
946 2001), namely the *Helmholtz function* $f(T, v) \equiv e - T\eta$ with the differential

$$947 \quad df = -\eta dT - pdv, \quad (\text{B.5})$$

948 the *Gibbs function* $g(T, p) \equiv f + pv = e - T\eta + pv$ with

$$949 \quad dg = -\eta dT + vdp, \quad (\text{B.6})$$

950 and the specific *enthalpy* $h(\eta, p) \equiv g + T\eta = f + T\eta + pv = e + pv$ with

$$951 \quad dh = Td\eta + vdp. \quad (\text{B.7})$$

952 Depending on the application purpose, each of these potential functions has certain advantages and
953 disadvantages, and having all of them optionally at hand in mutually consistent versions is most
954 useful.

955 Gibbs (1874-78) also considered a situation in which a given sample may exchange substance with its
956 surrounding. If the exchanged mass of substance i is dm_i , the related change of the sample's
957 (extensive) energy E at constant entropy and volume is termed the *chemical potential* μ_i of that
958 substance,

$$959 \quad dE = TdN - pdV + \sum_i \mu_i dm_i, \quad (B.8)$$

960 so that this exact differential implies that the chemical potential is obtained from

$$961 \quad \mu_i \equiv \left(\frac{\partial E}{\partial m_i} \right)_{N,V,m_{j \neq i}} = \left(\frac{\partial F}{\partial m_i} \right)_{T,V,m_{j \neq i}} = \left(\frac{\partial G}{\partial m_i} \right)_{T,p,m_{j \neq i}} = \left(\frac{\partial H}{\partial m_i} \right)_{N,p,m_{j \neq i}}. \quad (B.9)$$

962 Equilibrium of a spatially extended substance, in absence of gravity or accelerated motion, requires
963 that in addition to T and p , also the chemical potential μ_i separately for each present substance
964 needs to possess the same value anywhere in the volume. "The potential for each component
965 substance must be constant throughout the whole mass" (Gibbs 1874-78: p. 119).

966 As intensive properties, the specific energies cannot depend on the total mass but only on the mass
967 fractions, $w_i \equiv m_i/m$. Because by definition $\sum w_i = 1$, only $(n - 1)$ different fractions may be
968 independent variables describing the n components of a mixture. For example, one of the
969 components may be chosen as a master species, "0", such as a solvent, and the remaining ones, $i =$
970 $1, \dots, n - 1$, may denote the solutes.

971 In terms of T and p , chemical potentials are computed from the Gibbs function, g , through the Gibbs
972 energy, G , of eq. (B.9). Because the Gibbs function depends only on the independent intensive
973 variables, $g(w_i, T, p)$, the solutes' chemical potentials, $i > 0$, are

$$974 \quad \mu_i = \left(\frac{\partial G}{\partial m_i} \right)_{T,p,m_{j \neq i}} = \left(\frac{\partial(mg)}{\partial m_i} \right)_{T,p,m_{j \neq i}} = g + \left(\frac{\partial g}{\partial w_i} \right)_{T,p,w_{j \neq i}} - \sum_{j=1}^{n-1} w_j \left(\frac{\partial g}{\partial w_j} \right)_{T,p,w_{k \neq j}} \quad (B.10)$$

975 Similarly, the solvent's chemical potential is

$$976 \quad \mu_0 = \left(\frac{\partial G}{\partial m_0} \right)_{T,p,m_{j>0}} = \left(\frac{\partial(mg)}{\partial m_0} \right)_{T,p,m_{j>0}} = g - \sum_{j=1}^{n-1} w_j \left(\frac{\partial g}{\partial w_j} \right)_{T,p,w_{j>0}}. \quad (B.11)$$

977 Therefore, the *relative chemical potentials* of the solutes are simply the partial derivatives,

$$978 \quad \mu_i - \mu_0 = \left(\frac{\partial g}{\partial w_i} \right)_{T,p,w_{j \neq i}}. \quad (B.12)$$

979 For mixtures, $n > 1$, the differential (B.6) of the Gibbs function takes the more general form

$$980 \quad dg = -\eta dT + v dp + \sum_{i=1}^{n-1} (\mu_i - \mu_0) dw_i. \quad (B.13)$$

981 It follows straightforwardly from (B.10), (B.11) that the sum,

$$982 \quad \sum_{i=0}^{n-1} \mu_i m_i = m g = G, \quad (B.14)$$

983 equals the Gibbs energy itself (Gibbs 1874-78: eq. (96) therein, Guggenheim 1949, Landau and
984 Lifschitz 1966, Kittel 1969). In particular, if $n = 1$, the Gibbs function g of a pure substance
985 represents its chemical potential,

$$986 \quad g = \mu. \quad (B.15)$$

987 Where two phases of a pure substance are in contact at mutual equilibrium, such as saturated water
988 vapour at the liquid water surface, the mathematically distinct Gibbs functions of those phases take
989 equal values. This indispensable condition for mutual consistency between the thermodynamic

990 potentials of TEOS-10 is rigorously obeyed by virtue of appropriate reference-state conditions (Feistel
991 et al. 2008b).
