30 **Abstract**

31           Exceptional rainfall hit West Central Africa in October 2019. To understand the underlying  
32 mechanisms, we examined the regional moisture and Moist Static Energy (MSE) budgets intending  
33 to highlight the importance of the dynamic and thermodynamic effects associated with this historic  
34 event. Analysis of the moisture budget reveals that the precipitation anomalies in October were  
35 mainly controlled by dynamic effects. Horizontal moisture advection induced by horizontal wind  
36 anomalies controls extreme precipitation north of West Central Africa, while vertical moisture  
37 advection induced by vertical velocity anomalies controls extreme precipitation south of West  
38 Central Africa. Changes in the thermodynamic effect, although not the key factor responsible for the  
39 events of October 2019, contribute up to 35% of the total effect on the northern part and 15% on the  
40 southern part of the domain. The residual term on the northern part is important and provides a caveat  
41 when estimating dynamic and thermodynamic processes. Diagnosis of the MSE balance averaged  
42 over the northern part of west Central Africa shows that the anomalous vertical motion is dominated  
43 by the dynamic effect, i.e. the wet enthalpy advection induced by the horizontal wind anomalies. This  
44 is confirmed by the high spatial correlation ( $r = 0.6$ ) between the two terms compared to the other  
45 terms. Whereas to the west of the Congo Basin, the increase in the net energy balance dominated the  
46 changes in vertical motion ( $r = 0.51$ ). The horizontal advection of the MSE induced by the anomalies  
47 of the wet enthalpy and the vertical advection of the MSE induced by the anomalies of the MSE seem  
48 less important ( $r = 0.29$  and  $-0.19$  to the north and  $-0.17$  and  $0.03$  to the south respectively). The  
49 strong anomalies in the MSE balance in the north are linked to its meridional component, in  
50 particular the meridional wind anomalies in the dynamic effect and the meridional anomalies in latent  
51 heat in the thermodynamic effect. Our results suggest that dynamic and thermodynamic effects  
52 should be jointly considered for adequately anticipating this kind of extreme event. Understanding  
53 the associated mechanisms could help us improve our forecasts and projections, and increase the  
54 region's population resilience to these extreme weather events.

## 62 1 Introduction

63 Equatorial Africa recorded unprecedented amounts of rainfall in October and November 2019  
64 (Wainwright et al, 2020). Such a significant amount of precipitation is not without consequences for  
65 the population and the environment. In October, in most parts of East Africa in general, and in Kenya  
66 in particular, extreme rainfall led to flooding and landslides, provoking major destruction, with more  
67 than 100 deaths and around 18,000 people displaced internally and to neighbouring countries  
68 (<http://floodlist.com/africa/kenya-floods-november-2019>). In Central Africa, the Democratic  
69 Republic of Congo has been devastated by major flooding and forestry disruption along the Congo  
70 River, forcing many people to move (Gou et al. 2022). In the Central African Republic, extreme and  
71 persistent rainfall caused significant flooding and landslides, including the Oubangui River  
72 overflowing nearly 60 km of its coastline (Igri et al. 2023). In addition, the night of 27 to 28 October  
73 2019 was disastrous in the West Cameroon region, mainly in the locality of Bafoussam where  
74 extreme rainfall for about 36 hours caused a landslide, resulting in significant material damage with  
75 45 dead and others missing (Aretouyap et al. 2021; Mfondoum et al. 2021; Wantim et al. 2023). The  
76 episode was associated with a thermal depression over the Sahara and with anomalously high Sea  
77 Surface Temperatures (SST). The occurrence of these conditions may change in response to  
78 anthropogenic global warming, raising the question of whether devastating events such as the one of  
79 October 2019 could occur more frequently in the future (Nicholson et al. 2022). In particular, given  
80 that climate models predict an increasing trend in extreme rainfall in the region (Fotso-Nguemo et al.  
81 2018, 2019; Sonkoué et al. 2018; Tamoffo et al. 2019, 2023) and that extreme precipitation in the  
82 region is associated with vegetation dynamics (Zhou et al. 2014; Mariotti et al. 2014; Marra et al.  
83 2022; Garcin et al. 2018), it is crucial to understand the thermodynamic and dynamic mechanisms  
84 underlying these exceptional events of October 2019.

85 Recent studies have attempted to investigate the causes of extreme rainfall during the exceptional  
86 period of October 2019 in Equatorial Africa. Nicholson et al. (2022) showed that the heavy rainfall  
87 on the Guinean coast was reinforced by positive sea surface temperature anomalies along the Atlantic  
88 coast. This process leads to a significant advection of the moisture flux from the Atlantic, combined  
89 with the convergence of the moisture, which contributed to the increase in rainfall in the region  
90 (Pokam et al. 2011, Kuete et al. 2019). Wainwright et al. (2020) pointed out that the increase in  
91 rainfall over East Africa was a consequence of the positive phase of the Indian Ocean Dipole. Indeed,  
92 Black et al. (2005) reported that during periods of the year when the dipole mode index (DMI) IOD  
93 events are greater than  $0.5^{\circ}\text{C}$  over a period of 3 consecutive months and when the zonal SST gradient  
94 is reversed over several months, the resulting increase in rainfall over East Africa is important. In

95 addition, the positive IOD event of 2019 lasted from late summer through to December, influencing  
96 rainfall over East Africa.

97        Rainfall variability in Central Africa is highly dependent on the convergence of atmospheric  
98 moisture (Pokam et al. 2012; Washington et al., 2013; Dyer et al., 2017; Hua et al., 2019; Taguela et  
99 al. 2022; Tamoffo et al. 2023b,2024). Under the effect of global warming, the increase in extreme  
100 precipitation is a consequence of the increase in available atmospheric humidity (Nicholson et al  
101 2022). Although previous studies have focused on analyzing meteorological factors, there is still a  
102 general lack of knowledge about quantifying the dynamic and thermodynamic effects associated with  
103 these extremes of precipitation. In recent years, the decomposition of the water balance behind  
104 precipitation anomalies is often used to isolate the dynamic and thermodynamic contributions to  
105 extreme events (Li et al., 2017; Oueslati et al., 2019; Wen et al., 2022; Kenfack et al., 2023,2024).  
106 Water balance analysis has proved to be a useful tool for understanding anomaly fields in mean  
107 precipitation under the influence of global warming (Seager et al. 2014). Moist static energy (MSE),  
108 in particular, is a useful parameter for investigating the contribution of atmospheric moisture and  
109 analysing vertical velocity (Wang and Li, 2020a, 2020b; Bell et a. 2015; Neelin, 2021; Nana et al.  
110 2023; Andrews et al. 2023; Longandjo and Raoul, 2024; Kenfack et al. 2024). Recently, Kenfack et  
111 al. (2024) showed that, in the Congo Basin, the structure of the horizontal moisture advection  
112 anomalies is similar to that of the MSE advection anomalies during rainy seasons March-April-May  
113 (MAM) and September-October-November (SON). In addition, the atmospheric heating source has  
114 been identified as an indicator of precipitation (He et al. 2021). The increase in diabatic heating on  
115 the coast can contribute to the acceleration of near-surface winds (Pokam et al. 2014). An increase in  
116 this quantity implies an increase in latent warming, associated with a strong ocean-continent  
117 horizontal moisture gradient, which can lead to a strengthening of the boundary layer MSE, with a  
118 positive feedback process leading to extreme precipitation. Further, it has been demonstrated that a  
119 simultaneous reduction in the heating source and rainfall has been observed in reanalyses over recent  
120 decades in the Congo Basin (Kenfack et al. 2024). Given the highlighted importance of moisture,  
121 MSE and heating sources on rainfall variability, we adopt in this study an approach based on diabatic  
122 heating, water balance and MSE to diagnose dynamic and thermodynamic processes associated with  
123 the October 2019 rainfall extremes over West Equatorial Africa.

124        The remainder of the paper is structured as follows. A description of the observation and  
125 reanalysis data, and analysis methods is presented in Section 2. Section 3 describes the diabatic  
126 heating source and the performance of the reanalysis in capturing the October 2019 precipitation  
127 extremes. In Section 4, we investigate the dynamic and thermodynamic effects associated with the  
128 moisture balance. The analysis of the dynamic and thermodynamic effects associated with the MSE

129 budget during the October 2019 rainfall anomaly period over West Central Africa is presented in  
130 Section 5. Section 6 is conclusions and discussions.

131

## 132 **2 Data and methods**

### 133 **2.1. Data**

134 In this study, datasets from the fifth version of the European Centre for Medium-Range Weather  
135 Forecasts reanalysis, known as ERA5 (Hersbach et al., 2020), are used for the analyses. Johannsen  
136 et al. (2019) established that over equatorial Africa, ERA5 significantly improves over ERA-  
137 Interim (which represents the previous dataset), particularly in the description of the hydrological  
138 cycle. In addition, Cook and Vizzy (2021) have shown that ERA5 represents well the spatial  
139 distribution of precipitation and atmospheric dynamic fields compared with previous generations,  
140 particularly over the Congo Basin. With a spatial resolution of  $0.25^\circ \times 0.25^\circ$ , ERA5 is a global  
141 reanalysis dataset available from 1979 to the present, covering 137 pressure levels from the surface  
142 to 0.01 hPa. Monthly variables including horizontal and vertical wind components, geopotential,  
143 evaporation, humidity, heat flux and temperature are used in this study. For all variables, anomalies  
144 are obtained by removing the 30-year mean of the period 1988 to 2017. In order to reinforce the  
145 robustness of the results, several variables, such as winds (horizontal and vertical), specific  
146 humidity, precipitation and evaporation, obtained from the Modern-Era Retrospective Analysis for  
147 Research and Applications, version 2 (MERRA2), which provides data from 1980 to the present  
148 day (Gelaro et al., 2017), were used in this study. To assess ERA5's ability to detect October 2019  
149 precipitation extremes, we used three observational datasets, including rain gauge products and  
150 gauge-adjusted satellite products: the Climate Hazards Group InfraRed Precipitation with Stations  
151 (CHIRPS) gridded dataset, available at a resolution of  $0.05^\circ \times 0.05^\circ$  (Funk et al., 2015); the Global  
152 Precipitation Climatology Project (GPCP-v2.2) with a grid spacing of  $2.5^\circ \times 2.5^\circ$  (Huffman et al.,  
153 2009); the Climatic Research Unit (CRU-TS4.03) gridded data at a resolution of  $0.5^\circ \times 0.5^\circ$  (Harris  
154 et al., 2020).

155

### 156 **2.2 Methods**

#### 157 **2.2.1 Diabatic heating**

158 Apparent diabatic heating as proposed by Yanai and Tomita (1998) and Pokam et al. (2014) is  
159 defined as follows:

$$160 \quad Q = \chi \left( \frac{\partial \theta}{\partial t} + u \frac{\partial \theta}{\partial x} + v \frac{\partial \theta}{\partial y} + \omega \frac{\partial \theta}{\partial p} \right) \quad (1)$$

161 
$$\chi = c_p \left( \frac{T}{\theta} \right) \quad (2)$$

162 In equations 1 and 2,  $C_p$  (1,005 J Kg<sup>-1</sup> K<sup>-1</sup>) denotes the specific heat at constant pressure,  $\theta$  is the  
 163 potential temperature,  $\omega$  is the vertical velocity (hPa s<sup>-1</sup>), and  $V=(u, v)$  is the vector of horizontal  
 164 velocities.  $T$  (K) and  $p$  (hPa) represent the air temperature and the barometric pressure, respectively.

165 To quantify the monthly mean heating rate  $\tau$  (K day<sup>-1</sup>) related to apparent heating, we use the  
 166 relation:

167 
$$\tau = \frac{Q}{c_p} \quad (3)$$

168 where  $Q$  is the combination of heat from radiation, latent heat from condensation and the  
 169 convergence of vertical vortical transport of sensible heat.

170

## 171 2.2.2 Diagnosis of the moisture budget

172 The moisture budget used to quantify the contributions of evaporation and the horizontal and  
 173 vertical components associated with the circulation of moist air in the atmosphere (Seager et al.,  
 174 2010; Oueslati et al., 2019; Jiang et al., 2020; Moon and Ha, 2020; Wen et al., 2022; Zhao et al.,  
 175 2022; Sheng et al., 2023; Kenfack et al., 2024) is defined as follows:

176 
$$\langle \partial_t q \rangle + \langle \mathbf{V} \cdot \nabla_h q \rangle + \langle \omega \cdot \partial_p q \rangle = E - P \quad (4)$$

177 In Eq. 4,  $q$  represents the specific humidity,  $V=(u,v)$  denotes the horizontal wind and  $\omega$  the vertical  
 178 pressure velocity.  $E$  denotes surface evaporation and  $P$  precipitation. Angle brackets "<>" signify  
 179 the mass integral from the surface ( $p_s = 1000$  hPa) to a pressure  $p_t = 300$  hPa, which represents  
 180 the top of the atmosphere layer considered. The first term on the left of equation 4 can be neglected  
 181 given its small variation over time on a monthly scale and could contribute to the residuals (Wen et  
 182 al. 2022; Sheng et al. 2023). To estimate the horizontal and vertical moisture advection  
 183 components, we decompose equation 4 into its different linear and residual terms as follows:

184 
$$P' = E' - \langle \mathbf{V}' \cdot \nabla q' \rangle - \langle \mathbf{V}' \cdot \nabla \bar{q} \rangle - \langle \bar{\omega} \partial_p q' \rangle - \langle \omega' \partial_p \bar{q} \rangle + Res \quad (5)$$

185 In Eq. 5, the overbar indicates the monthly mean climatology from 1988 to 2017 and primes  
 186 indicate deviations from this climatology; The residual term "Res" contains the non-linear and  
 187 transient processes associated with the joint variations in water vapor content and circulation. The  
 188 terms  $\langle -\mathbf{V}' \cdot \nabla \bar{q} \rangle$  and  $\langle -\omega' \partial_p \bar{q} \rangle$  represent the dynamic contributions (or effect) and refer to  
 189 the moisture advection induced by the horizontal wind and by the vertical pressure velocity,

190 respectively. The terms  $\langle -\nabla \cdot \nabla q' \rangle$  and  $\langle -\bar{\omega} \partial_p q' \rangle$  represent the thermodynamic contributions  
 191 (or effect), and refer to the contribution of water vapor.

192

### 193 2.2.3 Diagnosis of the MSE budget

194 The MSE equation is defined as follows:

$$195 \quad \langle \partial_t (c_v T + L_v q) \rangle + \langle \mathbf{V} \cdot \nabla M \rangle + \langle \bar{\omega} \partial_p m \rangle = F_{net} \quad (6)$$

196 where the moist enthalpy is

$$197 \quad M = c_p T + L_v q \quad (7)$$

198 and the MSE is

$$199 \quad m = c_p T + L_v q + \Psi \quad (8)$$

200 In equations 7 and 8,  $c_p$  ( $c_v$ ) represents the specific heat at constant pressure ( the specific heat at  
 201 constant volume); T is the air temperature and  $\Psi$  the geopotential.  $F_{net}$  is the net energy entering  
 202 the atmospheric column at the surface and top of the atmosphere (latent heat, sum of sensible heat,  
 203 and shortwave and longwave radiative fluxes). Similar to the moisture flux equation, the first term on  
 204 the left of equation 6 can be neglected given its small variation over time on a monthly scale and  
 205 contributes to the residuals. In addition, it should be noted that variations in geopotential height  
 206 along pressure levels are neglected in this formulation of the MSE budget. The remaining terms in  
 207 equation 6 can be decomposed into horizontal and vertical advection components, as described by:

$$208 \quad \langle \omega' \partial_p \bar{m} \rangle = -\langle \nabla \cdot \nabla M' \rangle - \langle \mathbf{V}' \cdot \nabla M \rangle - \langle \omega \partial_p m' \rangle + F'_{net} + Res \quad (9)$$

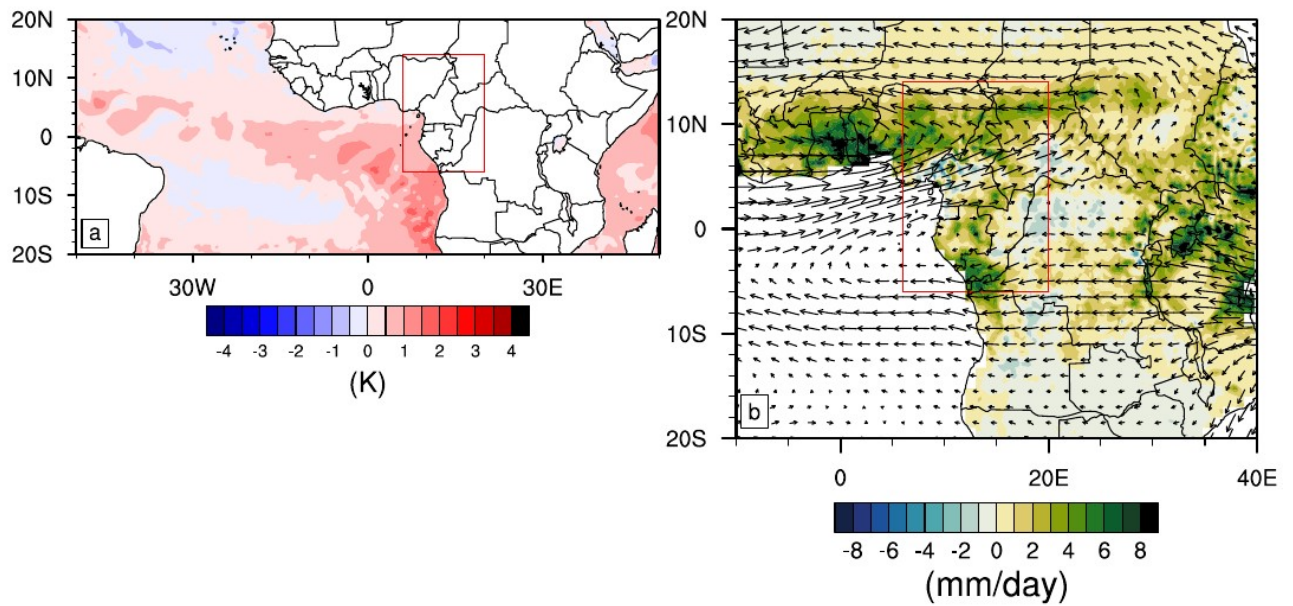

209 Anomalous vertical motion is analysed using this equation with a given profile of  $\bar{m}$ . Similar to the  
 210 convention adopted for decomposing the moisture flux, the term  $-\langle \mathbf{V}' \cdot \nabla M \rangle$  relates to the  
 211 anomalous MSE associated with the atmospheric circulation and contains the dynamic contribution  
 212 (or effect), while the two terms  $-\langle \nabla \cdot \nabla M' \rangle$  and  $-\langle \omega \partial_p m' \rangle$  refer to the thermodynamic  
 213 contribution (or effect), which is crucial for diagnosing the thermal state of the atmosphere  
 214 associated with the increase in the vertical rise of the air.

215

## 216 3 Diabatic heating and extreme rainfall

217 The increase in SSTs in the eastern Atlantic (Fig. 1a) has been identified as one of the causes of the  
 218 positive precipitation anomalies over western central Africa in October 2019. The warming contrast

219 between the ocean and the continent favoured the strengthening of the moisture advection  
220 associated with the precipitation anomalies over West Central Africa (Fig. 1b). This is in agreement  
221 with Nicholson et al. (2022).

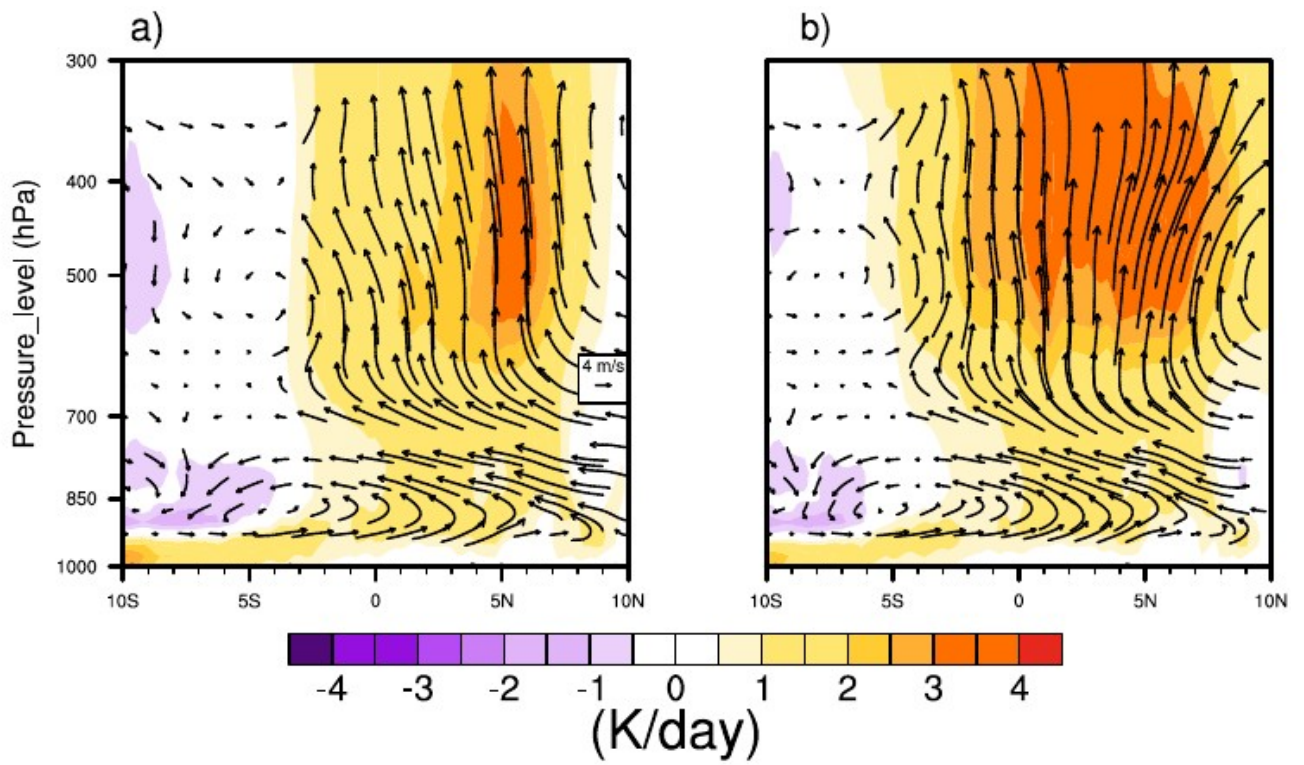

222

223 **Fig 1.** SST a) and rainfall b) anomalies during October 2019. The vectors represent anomalies of  
224 vertically integrated atmospheric moisture flux. The red box indicates the Central West Africa area.

225 Figure 2 represents the mean vertical profile (pressure-latitude) of diabatic heating averaged  
226 between 6° and 20°E during SON for the 1988-2017 climatology (Fig. 2a) and the corresponding  
227 profile for 2019 (Fig. 2b). During SON, the main source of heat is located between 3°S and 9°N for  
228 climatology, and between 5°S and 13°N for 2019.

229

230

231 **Fig 2.** Diabatic heating and divergent meridional circulation (vectors;  $m s^{-1}$ ) during the SON  
 232 season for a) 1988-2017 avg, b) 2019 avg and c) the anomaly, all averaged between the 6° and

233 20°E. As the vertical velocity is much weaker than the meridional wind, its values have been  
234 enhanced by a factor of 600 for the clarity of the graph.

235

236 However, 2019 presents a more extensive and pronounced source of heat compared with the  
237 climatology 1988-2017. A 3-4  $K day^{-1}$  heating, more intense in 2019, occurred from 600 hPa. A  
238 cooling of 1- 2  $K day^{-1}$  took place around 850 hPa in the south and from 550 hPa in the north. The  
239 profound heating observed from 600 hPa originates at the surface on the southern portion of the  
240 domain (10°S). It is reinforced by the contrast between the large positive values and the negative  
241 values on either side of the equator between 500 and 400 hPa. The vertical structure of the  
242 divergent circulation is also illustrated in Figure 2. The divergent circulation appears more  
243 pronounced from 550 hPa in 2019 (Fig. 2b) compared with the climatology of 1988-2017 (Fig. 2a).  
244 This is consistent with the warming contrast observed. This uplift was reinforced by the warming of  
245 the equatorial Atlantic associated with an abnormally strong thermal low over the Sahara, which led  
246 to an acceleration of the dominant meridional flow in the divergent circulation (Fig. 2c). This is in  
247 agreement with Nicholson et al. (2022), who highlighted that the West African monsoon was late to  
248 withdraw in 2019.

249         Although the SON season has shown significant diabatic heating compared to climatology,  
250 October 2019 in particular over West Central Africa recorded extremes of rainfall (Nicholson et al.  
251 2022). In this study, we use the ERA5 reanalysis precipitation fields for water balance analysis.  
252 This ensures that all the examined physical quantities are consistent across the study. Before doing  
253 so, we assessed the performance of ERA5 in detecting the extreme precipitation events in October  
254 2019. Figure 3 illustrates the interannual variability of October rainfall anomalies over West Central  
255 Africa for the period 1987-2021.

256

257 **Fig 3.** Temporal evolution of October rainfall anomaly over West Central Africa (6°S-14°N, 6°-  
 258 20°E), from reanalysis data ERA5 (red) and from observational data CHIRPS (blue), GPCP  
 259 (maroon) and CRU (black), covering the period 1987–2021.

260

261 The ERA5 reanalysis (red) and the CHIRPS (blue), GPCP (maroon) and CRU (black) observations  
 262 are consistent in highlighting the high precipitation peak of 2019. CHIRPS shows the highest values  
 263 of positive anomalies of up to 3.5 mm day<sup>-1</sup>, while ERA5 shows values of up to 2.5 mm day<sup>-1</sup>.  
 264 Despite some differences between ERA5 and the observations in representing trends on an  
 265 interannual scale (Kenfack et al. 2024), the unprecedented event of October 2019 was well detected.  
 266 In addition, the exceptional event is also detected by the MERRA2 reanalysis (Figure S1)

267 The increase in SSTs in the tropical Atlantic reached a record level in October 2019  
 268 (Nicholson et al. 2022). This may have resulted in an increased specific humidity over land. Figure  
 269 4 depicts the vertical profile (pressure level-latitude) of specific humidity (colors) and meridional  
 270 wind (contours) averaged between 6° and 20°E for the 1988-2017 climatology (Fig. 4a), the  
 271 October 2019 average (Fig. 4b), and the October 2019 anomaly (Fig. 4c).

272

273

274 **Fig. 4.** Specific humidity and meridional wind (contours: m/s) in October for a) 1988-2017 avg, b)  
 275 2019 avg and c) the anomaly, averaged between 6°-20°E.

277 The 1988-2017 climatology is characterized by intense surface specific humidity extending as far as  
 278 12°N, whereas the October 2019 average appears to extend further to 15°N. In addition, the  
 279 southerly wind in 2019 was more pronounced up to 15°N compared to the climatology. Analysis of  
 280 the anomalies confirms that the humidity extended further north in West Central Africa in October  
 281 2019, compared with the climatology. The intensification of the southerly wind up to 15°N  
 282 indicates that this moisture probably comes from the equatorial Atlantic. This is in agreement with  
 283 Kamae et. al (2017), who highlighted that extreme precipitation can be a consequence of changes in  
 284 humidity. Indeed, the increase in humidity associated with a substantial heating source contributes  
 285 to an increase in precipitation.

286

#### 287 **4 Moisture budget analysis**

288 Rainfall variability in equatorial Central Africa is strongly dependent on the moisture inputs  
 289 associated with atmospheric circulation (Jackson et al., 2009; Cook and Vizy, 2016, 2022; Dyer et  
 290 al., 2017; Longandjo and Raoul, 2024). In the Congo Basin, atmospheric heating sources combined  
 291 with the vertical advection of moisture induced by anomalous vertical motion are responsible for  
 292 most of the interannual variability of precipitation (Kenfack et al., 2024). In this section, we  
 293 decompose the moisture budget in equation 5 to examine the processes that led to the October 2019  
 294 extreme rainfall over West Central Africa. To do this, we analyse local variations in rainfall  
 295 associated with atmospheric moisture introduced into the air column by atmospheric circulation.

296 The monthly anomalies of the different components of the water balance averaged over the  
 297 northern part of west-central Africa (6°N-14°N, 6°-20°E) for the month of October 2019 (Fig. 5a)  
 298 indicate that the increase in dynamic processes dominated the increase in precipitation. Horizontal  
 299 advection of moisture induced by the horizontal wind anomaly  $\langle -\mathbf{v}' \cdot \nabla \bar{q} \rangle$  was the most  
 300 pronounced component (up to 2.5 mm/day). Although thermodynamic processes  $\langle -\mathbf{v} \cdot \nabla q' \rangle$  and  
 301  $\langle -\bar{\omega} \partial_p q' \rangle$  are weaker than dynamic processes, they also contributed to the extreme rainfall  
 302 amounts. Evaporation  $E$ , for its part, contributed very little (0.1 mm/day). This is consistent with  
 303 Cook et al. (2019) who found that rainfall anomalies in equatorial Central Africa do not depend  
 304 directly on surface heating. It should also be noted that the residual term for a value of -1.2 mm/day  
 305 is considerable. Indeed, the northward shift and strengthening of the northern component of the  
 306 East African Jet (AEJ-N) in October are verified (Nicholson et al. 2022). This is illustrated by the

307 anomalous 700 hPa zonal wind in October 2019. In addition, the anomalous variance of the band-  
308 pass filtered 700 hPa meridional wind over 2-6 days is also visible, indicating African easterly wave  
309 activity (Reed et al., 1977). Other studies also point out that rainfall fluctuations in equatorial  
310 Africa are associated with Kelvin waves (Jackson et al., 2019). The residual term could influence the  
311 estimation of dynamic and thermodynamic distributions in the water budget, and its high values in  
312 the Sahel region would be associated with a non-linear interaction between wind and changes in  
313 humidity.

314 Analysis of the components of the water balance over the western part of the Congo Basin  
315 (6°S-5°N, 6°-20°E) for October 2019 (Fig. 5b) shows that the increase in rainfall was dominated by  
316 vertical advection of moisture induced by changes in vertical velocity  $\langle -\omega' \partial_p \bar{q} \rangle$  (1.4 mm/day ).  
317 However, the contributions of the other processes, including the residual term, are low.

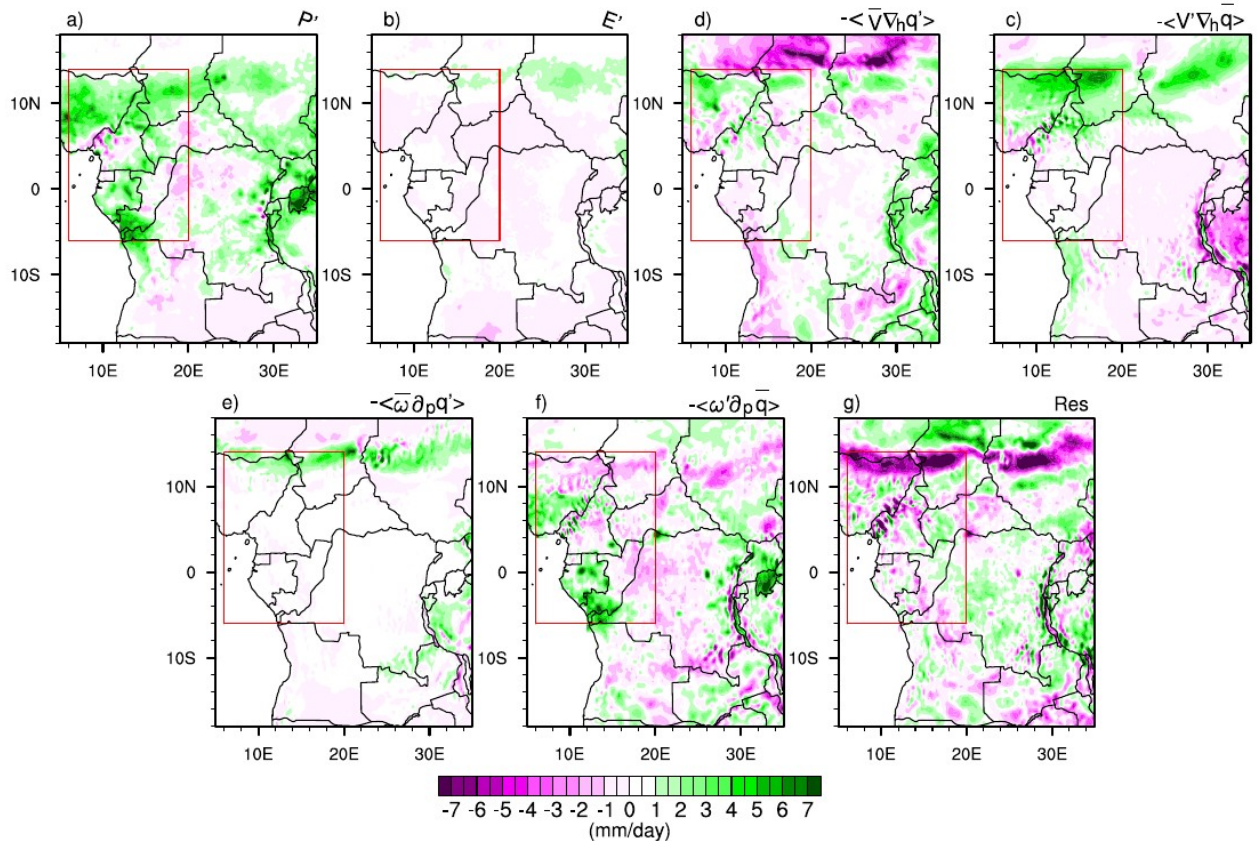

318

319

320 **Fig. 5** Monthly mean anomalies in moisture budget for October 2019, averaged in a) over the  
 321 Northern part of West Central Africa (6°N-14°N, 6°-20°E) and b) over the Southern part of West  
 322 Central Africa (6°S-5°N, 6°-20°E)

323 At the pixel scale, positive precipitation anomalies over eastern Nigeria, southern Chad and  
 324 northern Cameroon (Fig. 6a) were mainly dominated by horizontal moisture advection induced by  
 325 the horizontal wind anomaly (Fig. 6d). Over Gabon, south of Congo Brazzaville, positive  
 326 precipitation anomalies were dominated by vertical moisture advection induced by vertical  
 327 anomalous motion (Fig. 6f). Horizontal moisture advection induced by the specific humidity  
 328 anomaly (Fig. 6c), although not the key factor associated with precipitation patterns, shows a small  
 329 positive contribution over the northern part of the domain.

330  
 331 **Fig. 6.** Spatial distributions of each term of the water budget equation during October 2019 over West  
 332 Equatorial Africa (Red box). (a) Precipitation anomalies, (b) evaporation anomaly, (c) horizontal  
 333 advection of anomalous moisture by climatological wind, (d) horizontal advection of climatological  
 334 moisture by anomalous wind, (e) vertical advection of anomalous moisture by climatological vertical  
 335 velocity, (f) vertical advection of climatological moisture by anomalous vertical velocity and (g) the  
 336 residual term.

337  
 338 The contribution of evaporation (Fig. 6b) and horizontal advection of moisture induced by the  
 339 specific humidity anomaly (Fig. 6e) remains weak over the entire domain, although some positive

340 values can be seen around 14°N. This result is similar to that provided by MERRA2 (Figure S2).  
341 Thermodynamic effects reflect the change in the thermal state of the atmosphere associated with the  
342 October 2019 rainfall extremes over West Central Africa. However, changes in the thermodynamic  
343 effect, although not the key factor responsible for the October 2019 events, contributed up to 35%  
344 of the total effect (the sum of dynamic and thermodynamic contributions) on the northern part and  
345 15% on the southern part of the domain. This could be since the increase in diabatic heating  
346 contributes to the change in the thermal state of the atmosphere, i.e. the increase in  
347 thermodynamic effects (changes in humidity). In fact, Nicholson et al. (2022) reported that the  
348 increase in SST in the tropical Atlantic strengthened the advection of moist air from the Atlantic  
349 towards the region, with an increase in the moisture flux from the west to southwest.

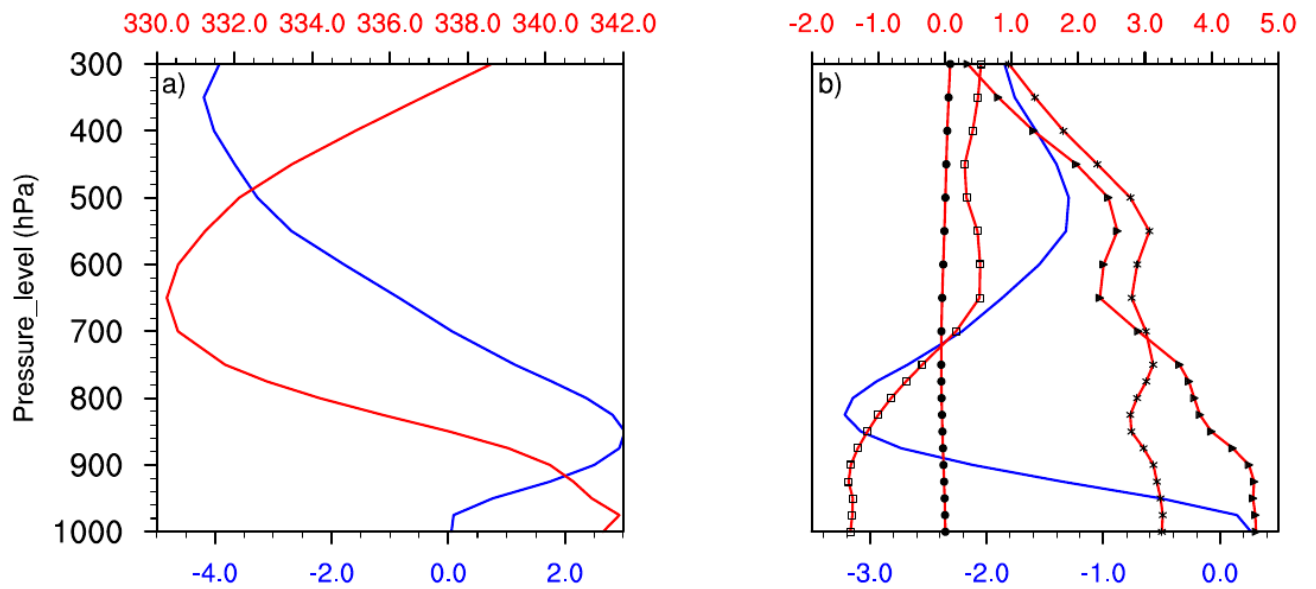

350

## 351 5 MSE budget analysis

352 The previous results clearly showed that the vertical advection of moisture induced by the  
353 vertical velocity anomaly was identified as the second dynamic parameter (after the horizontal  
354 advection of moisture induced by the anomalous horizontal movement) contributing to the  
355 increase in precipitation in October 2019. Diagnosis of the MSE budget, which takes account of the  
356 thermal state of the atmosphere and the effect of atmospheric circulation, is used to analyse the  
357 atmospheric perturbation related to moisture transport. The MSE largely influences the structure of  
358 vertical motion. In addition, diagnosis of the MSE balance emphasises the relative contributions of  
359 temperature, specific humidity and atmospheric circulation associated with the vertical motion  
360 anomaly.

361 The vertical profiles of the vertical velocity anomaly  $\omega'$  and the MSE climatology  $\bar{m}$   
362 averaged over the north of the domain are shown in Figure 7a. The vertical velocity anomaly  $\omega'$   
363 shows positive values at the surface and negative values in the middle and upper troposphere. The  
364 alternation of positive and negative values in the tropospheric column probably reduces the  
365 contribution of the vertical advection of moisture induced by the anomalous vertical motion. The  
366 MSE climatology  $\bar{m}$  exhibits a bottom-heavy structure with a minimum around 650 hPa. Such a  
367 structure generally indicates that  $\langle \partial_p \bar{m} \rangle < 0$  (Chen and Bordoni, 2014; Liu et al. 2021; Wen et al.  
368 2022). As a result, positive (negative) values of  $\langle \omega' \partial_p \bar{m} \rangle$  depends on the vertical structure of the  
369 omega anomalies. The vertical velocity climatology  $\bar{\omega}$  (Fig. 7b) is negative over the entire

370 troposphere, characterising an upward movement. The MSE anomaly  $m'$  decreased slightly near  
 371 the surface then increased from 800 hPa to 550 hPa, with a minimum value around 550 hPa.  
 372 However, this includes three terms, namely,  $gz'$  which is weak in the entire tropospheric column,  
 373 the enthalpy anomaly  $c_p T'$ , which tends to increase, and  $l_v q'$ , tends to behave similarly to  $m'$   
 374 between 650 hPa and 300 hPa. To the south of the domain (Fig. 7c), the vertical velocity anomaly  
 375 shows negative

376

377

378 **Fig. 7.** Vertical profile of a) vertical velocity anomaly  $\omega'$  (blue line:  $10^{-2} Pa.s^{-1}$ ) and MSE  
 379 climatology  $\bar{m}$  (red line:  $10^3 J.Kq^{-1}$ ), and b) vertical velocity climatology  $\bar{\omega}$  (blue line:  
 380  $10^{-2} Pa.s^{-1}$ ), MSE anomaly  $m'$  ( line with stars:  $10^3 J.Kq^{-1}$ ), enthalpy anomaly  $c_p T'$  (line with  
 381 squares:  $10^3 J.Kq^{-1}$ ), latent energy anomaly  $l_v q'$  (line with triangles:  $10^3 J.Kq^{-1}$ ) and  
 382 geopotential anomaly  $\Psi'$  (line with dark circle:  $10^3 J.Kq^{-1}$ ) averaged over the Northern part of  
 383 West Central Africa (6°N-14°N, 6°-20°E) and c), d) the same parameters averaged over the  
 384 Southern part of West Central Africa (6°S-5°N, 6°-20°E) during October 2019.

385

386 values from 900 hPa up to the upper troposphere, accelerating the anomalous vertical movement.  
 387 The structure of the MSE climatology is similar to that observed to the north, with a maximum of  
 388 around 650 hPa. The vertical profiles (Fig. 7d) of the MSE anomaly and the latent energy anomaly  
 389 show similar structures throughout the tropospheric column, with maximum values at 650 hPa.

390 Based on the contributions of the different terms in equation 9 to the MSE over the northern  
 391 part of West Central Africa (Fig. 8a), the advection of wet enthalpy induced by the horizontal wind  
 392 anomalies  $-\langle \mathbf{v}' \cdot \nabla M \rangle$  is the main term contributing most to the vertical advection of the MSE  
 393 induced by the vertical velocity anomaly  $\langle \omega' \partial_p \bar{m} \rangle$ . This is confirmed by the high correlation ( $r =$   
 394 0.6) between the two terms compared to the other terms.

395 We also note the contribution of the thermodynamic terms, although the horizontal advection of the  
396 MSE induced by the wet enthalpy variation  $-\langle \nabla \cdot \nabla M' \rangle$  dominates ( $r = 0.3$ ) compared to the  
397 vertical advection of the MSE induced by the MSE variation  $-\langle \omega \partial_p m' \rangle$  ( $r = -0.2$ ). A weak  
398 contribution from the net flow of energy is noticeable ( $r = 0.18$ ). This could be due to the fact that  
399 the energy in the radiative and turbulent heat fluxes penetrating the atmosphere over West Central  
400 Africa has suffered a loss linked to the increase in cloud cover, which has a strong influence on  
401 short-wave radiation. Such a reduction in energy in the air column has an impact on upward motion.  
402 This result is in line with that of Wen et al. (2022) and Sheng et al. (2023), who pointed to a  
403 reduction in the net energy in the air column during the exceptional rainy season in the summer of  
404 2020 in the Yangtze River valley and the anomalous increase in precipitation over southern China  
405 in 2022. However, as with the moisture balance, the residual term is also considerable.

406

407 **Fig. 8.** Different terms of the Moist Static Energy (MSE) budget averaged in a) over the Northern  
 408 part of West Central Africa (6°N-14°N, 6°-20°E) and b) over the Southern part of West Central  
 409 Africa (6°S-5°N, 6°-20°E).

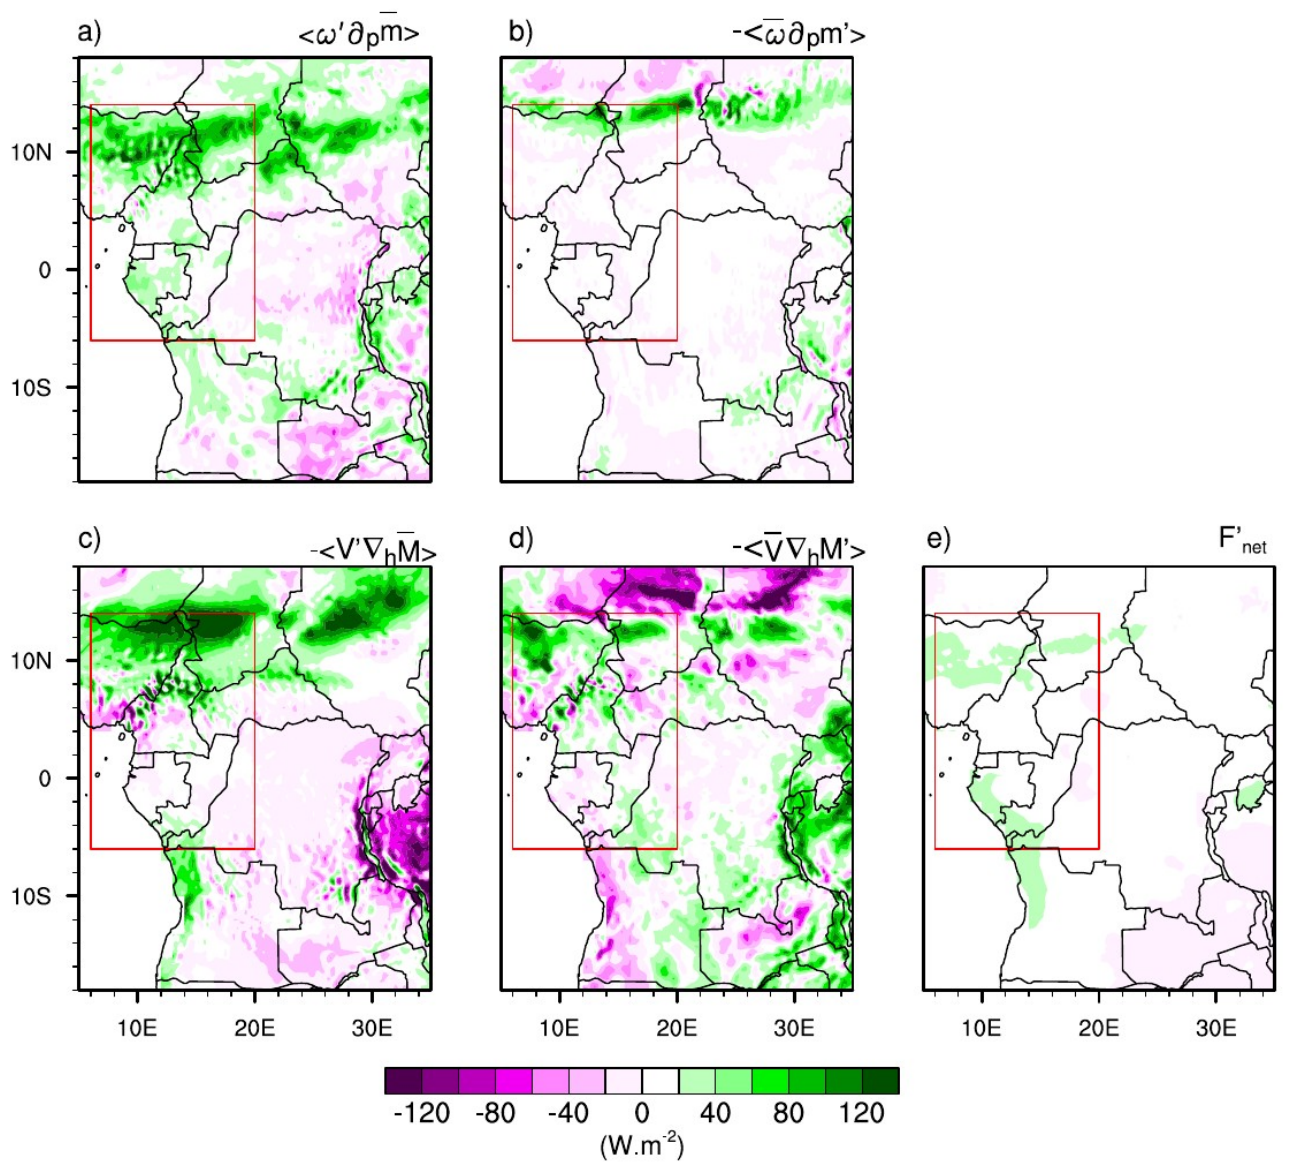

410

411 To the south of the domain(Fig. 8b), the increase in the net energy balance was responsible for  
412 strengthening the vertical advection of the MSE induced by the vertical velocity anomaly ( $r = 0.51$ ).

413 In addition, the increase in vertical movement was reinforced by an increase in the horizontal  
414 advection of the MSE induced by the variation in wet enthalpy  $-\langle \nabla \cdot \nabla M' \rangle$ . This is in agreement  
415 with the results of Kenfack et al. (2024) who highlighted the importance of horizontal advectons in  
416 the MSE and moisture flux as well as their implications for vertical motion over the Congo Basin.  
417 The contributions in vertical advection induced by changes in the MSE and horizontal advection  
418 induced by changes in the horizontal wind are small. Moreover, similarly to the moisture flux  
419 advected in the western part of the Congo Basin, the residual term was less important in the MSE  
420 budget compared to the northern part.

421 On a regional scale, the vertical advection of the MSE induced by the vertical motion anomaly  
422  $\langle \omega' \partial_p \bar{m} \rangle$  (Fig. 9a) is mainly dominated by the dynamic term  $-\langle \mathbf{V}' \cdot \nabla M' \rangle$  (Fig. 9c), which brings

423 moist enthalpy into the domain.

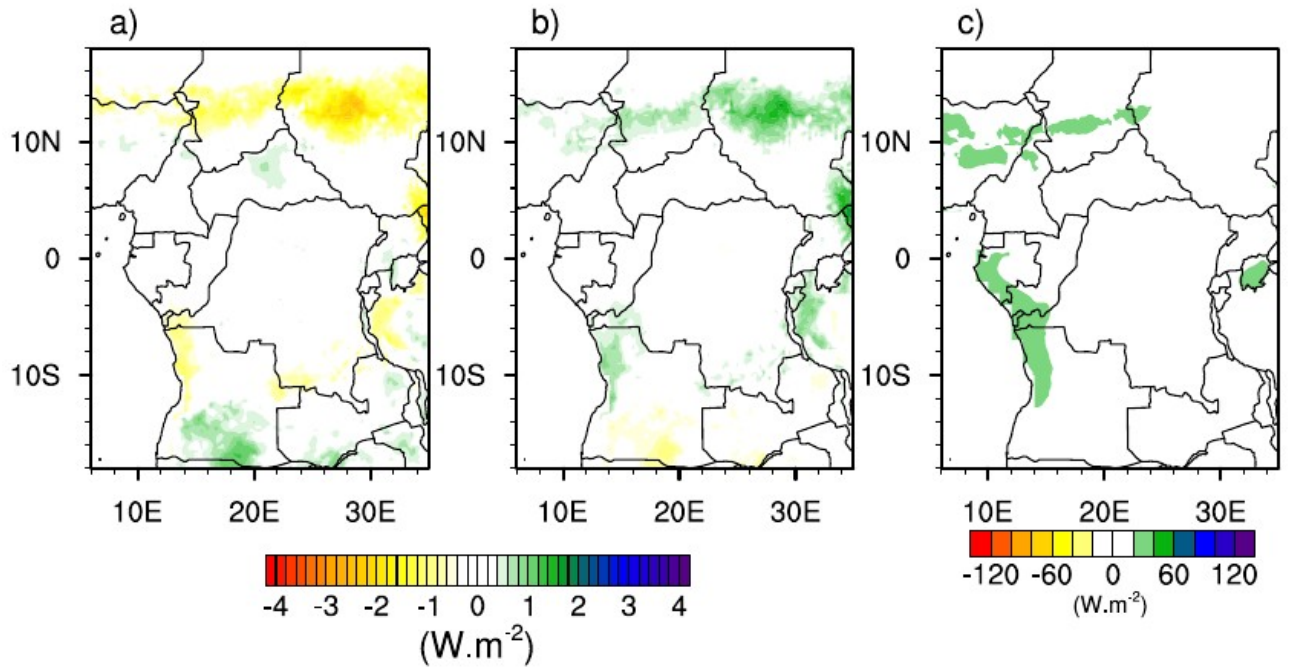

425 **Fig. 9.** Spatial distributions of each term of the Moist Static Energy (MSE) balance equation during  
 426 October 2019 over West Equatorial Africa (Red box). (a) vertical advection of climatological MSE  
 427 by anomalous vertical velocity, (b) vertical advection of anomalous MSE by climatological vertical  
 428 velocity, (c) horizontal advection of anomalous moist enthalpy by climatological wind, (e) horizontal  
 429 advection of climatological moist enthalpy by anomalous wind, and (f) net energy flux (at the surface  
 430 and top of the atmosphere) in the atmospheric column.

431 There is a high concentration of positive values in both dynamic terms, up to  $120 \text{ W}\cdot\text{m}^{-2}$  in the  
 432 north of West Central Africa. In addition, the two thermodynamic terms  $-\langle \omega \partial_p m' \rangle$  (Fig. 9b) and  
 433  $-\langle \nabla \cdot \nabla M' \rangle$  (Fig. 9d), although weak, also contributed to reinforcing the vertical advection of  
 434 MSE induced by the vertical motion anomaly. It should be remembered that the term  $-\langle \omega \partial_p m' \rangle$   
 435 remains very weak over the region as a whole, except the northern part where a slight layer of  
 436 positive values can be observed. Terms  $-\langle \mathbf{V}' \cdot \nabla M \rangle$ ,  $-\langle \nabla \cdot \nabla M' \rangle$  and  $-\langle \omega \partial_p m' \rangle$  in the MSE  
 437 have a similar spatial distribution to terms  $\langle -\mathbf{V}' \cdot \nabla \bar{q} \rangle$ ,  $\langle -\nabla \cdot \nabla q' \rangle$  and  $\langle -\bar{\omega} \partial_p q' \rangle$  in the  
 438 moisture, which is in agreement with the findings of Kenfack et al. (2024). The difference between  
 439 the net energy balance for 2019 and the climatology (Fig. 9e) shows low positive values in the north  
 440 and south of the region respectively. Such an increase (mainly to the south of the area) is associated  
 441 with a strengthening in the vertical structure of the MSE anomaly through ascending currents and,  
 442 consequently, an increase in precipitation. A further analysis of the net energy balance (Fig. 10)  
 443 shows that during October 2019, the latent heat flux (Fig. 10a) decreased mainly over the Sahel and  
 444 to the south of the domain. Sensible heat, on the other hand, increased slightly, with values of  
 445 around  $1.5 \text{ W}\cdot\text{m}^{-2}$ . Analysis of the radiative flux anomalies shows strong positive values over the  
 446 Sahel and the southern part of the domain (up to  $50 \text{ W}\cdot\text{m}^{-2}$ ), showing that this is the main factor  
 447 responsible for the increase in the energy balance during the exceptional event of October 2019.

448

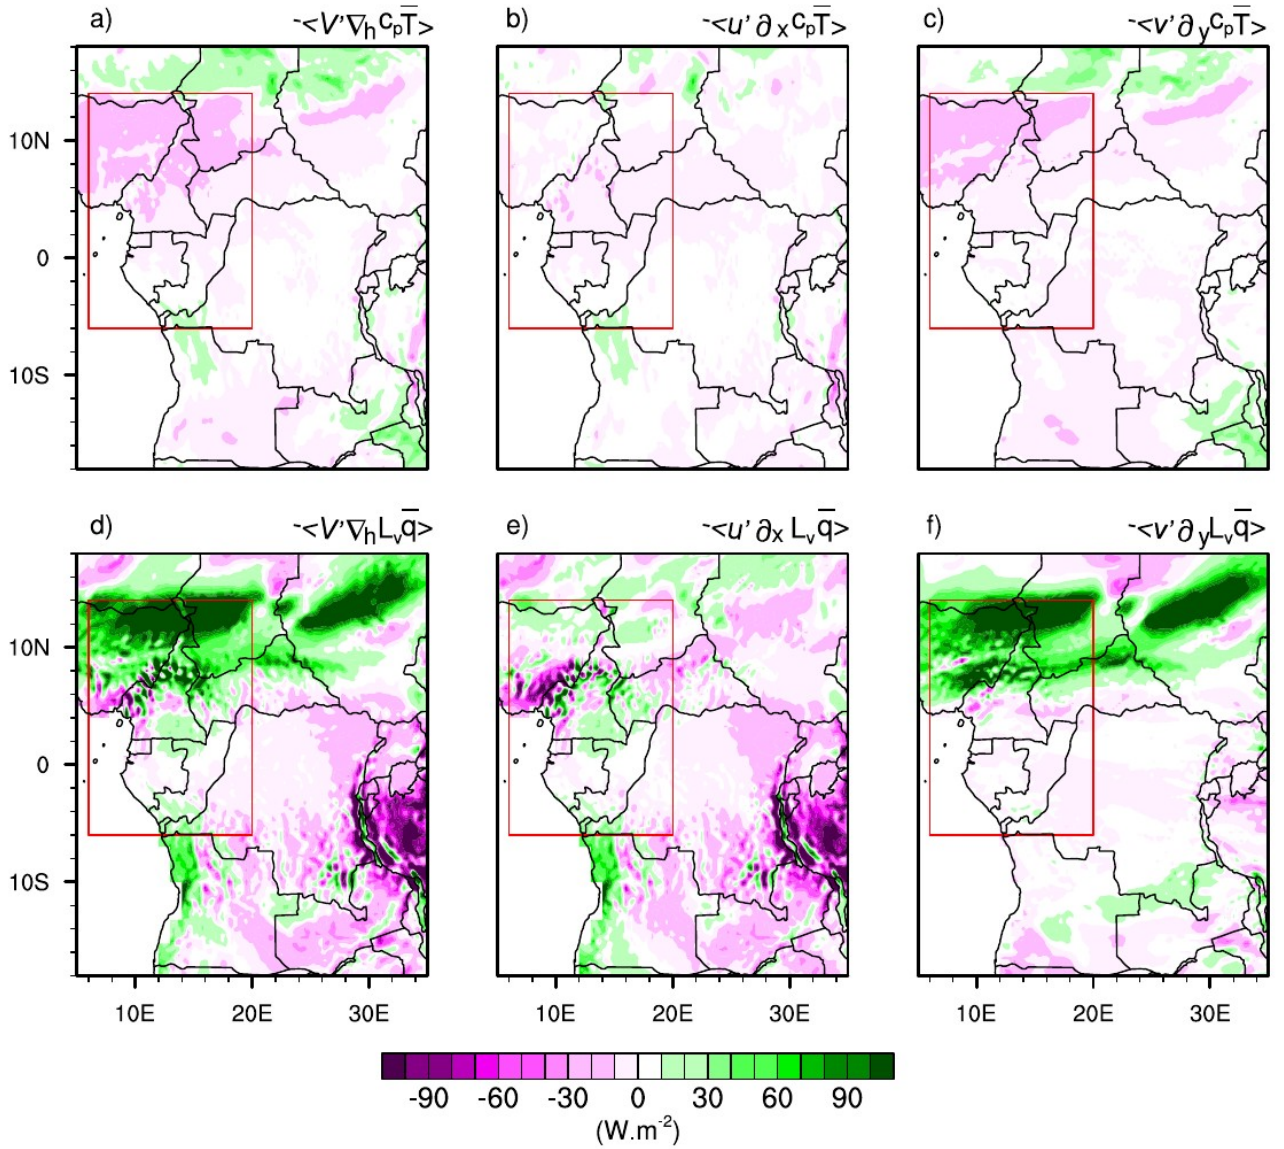

449

450 **Fig. 10.** Spatial distribution of a) latent heat, b) sensible heat and c) radiative flux anomalies in  
 451 October 2019 over western equatorial Africa.

452 Although the dynamic contribution is the most important, the thermodynamic contribution cannot  
 453 be neglected. This would mean that the interaction between atmospheric dynamic and  
 454 thermodynamic variables would induce significant indirect effects on October 2019 precipitation  
 455 anomalies over West Central Africa.

### 456 5.1 Dynamic effect

457 The aforementioned results clearly show that enthalpy advection induced by the horizontal wind  
 458 anomaly is crucial in understanding the processes at the origin of October 2019 extreme  
 459 precipitation over northern part of West Central Africa. It should be remembered that, as we  
 460 mentioned in the diagnostic section of the MSE balance, the wet enthalpy  $M = c_p T + L_v q$  results  
 461 from the sum of the dry enthalpy and the latent heat. Thus, the horizontal advection of wet enthalpy  
 462 induced by the wind anomaly can be separated into two terms: dry enthalpy  $-\langle \mathbf{V}' \cdot \nabla_h c_p T \rangle$  (Fig.  
 463 11a) and latent heat  $-\langle \mathbf{V}' \cdot \nabla_h L_v \bar{q} \rangle$  (Fig. 11d).

464

465 **Fig. 11.** Horizontal advection of (a–c) climatological dry enthalpy and (d–f) latent energy by  
 466 anomalous wind, designated as a dynamic effect during October 2019 over West Central Africa  
 467 (Red box). (a, d) Total advection, (b, e) zonal component, and (c, f) meridional component.

468

469 Given the influence of the wind anomaly components on the displacement of dry enthalpy and  
 470 latent heat, a further decomposition of the  $-\langle V' \cdot \nabla_h c_p \bar{T} \rangle$  and  $-\langle V' \cdot \nabla_h L_v \bar{q} \rangle$  terms along the  
 471 zonal (Figs. 11b,e) and meridional (Figs. 11c,f) directions appear necessary. Figure 11a shows that  
 472 the advection of dry enthalpy induced by the horizontal wind anomaly decreased over the area-  
 473 averaged, with the highest values between 6°N and 14°N. The advection of dry enthalpy by the  
 474 meridional wind anomaly (Fig. 11c) is particularly responsible for the decrease in the

475  $-\langle \mathbf{V}' \cdot \nabla_h c_p T' \rangle$  term compared with the advection of dry enthalpy induced by the zonal wind  
476 anomaly (Fig. 11b), which is weak. For the transport of latent heat (Fig. 11d), the influence of the  
477 advection of  $-\langle \mathbf{V}' \cdot \nabla_h l_v \bar{q}' \rangle$  term under the effect of the anomalous meridional circulation is the  
478 main term responsible for the supply of moist air to the northern part of the area, while the low  
479 contribution to the south is associated with a low input of moist air from the zonal wind anomaly  
480 (Fig. 11f). Analysis of the advection of dry enthalpy and latent heat by anomalous winds shows that  
481 the meridional wind anomaly had a significant impact compared with the zonal wind anomaly. In  
482 addition, the advection of the dynamic term associated with latent heat contributed significantly to  
483 the supply of MSE to West Central Africa compared to the advection of the dynamic term  
484 associated with dry enthalpy. One of the reasons would be because in addition to the warm Atlantic  
485 SSTs, there was also an anomalous meridional mean sea level pressure (MSLP) gradient in the  
486 Central African Sahel between a lower MSLP over the eastern Sahara and a higher pressure  
487 between 10 and 15°N. In addition, the trans-equatorial meridional wind fluctuated with the activity  
488 of the African easterly waves over the Gulf of Guinea (Nicholson et al. 2022).

## 489 5.2 Thermodynamic effect

490 The results of the previous section highlighted the importance of dynamics, particularly in a  
491 meridional direction, on extreme precipitation in October 2019. However, we previously also  
492 observed that the thermodynamic contribution should not be neglected. Similar to the previous  
493 section, the thermodynamic term  $-\langle \mathbf{V}' \cdot \nabla M' \rangle$  ( i.e. the advection of the wet enthalpy anomaly  
494 associated with wind climatology) can also be separated into two terms, namely: Dry enthalpy  
495  $-\langle \mathbf{V}' \cdot \nabla_h c_p T' \rangle$  (Fig. 12a) and latent heat  $-\langle \mathbf{V}' \cdot \nabla_h l_v \bar{q}' \rangle$  (Fig. 12d).

496

497 **Fig. 12.** As in Fig. 11, but for the thermodynamic effect (horizontal advection of anomalous dry  
 498 enthalpy and latent energy by climatological wind) during October 2019 over West Central Africa  
 499 (Red box).

500

501 To better assess the contribution of each term, we split the horizontal wind into zonal and  
 502 meridional directions. The advection of the dry enthalpy anomaly by the horizontal zonal and  
 503 meridional wind components is shown in Figures 12b and 12c, respectively. It can also be seen that  
 504 the dry enthalpy anomaly is very small over the whole area. On the other hand, the advection of the  
 505 latent heat anomaly by the horizontal wind climatology is more pronounced. Variations in latent  
 506 heat are strong in the meridional direction, while the zonal direction shows a reduction in abnormal  
 507 latent heat. This could be due to the strong meridional wind associated with the increase in SST in

508 the tropical Atlantic, which results in strong advection of water vapor into West Central Africa,  
509 leading to precipitation. The reduction in advection of the latent heat anomaly on the Atlantic coast  
510 is amplified by the zonal wind climatology. However, the advection of the wet enthalpy induced by  
511 the horizontal wind anomaly (dynamic effect) is stronger than the advection of the wet enthalpy  
512 anomaly by the wind climatology. As a result, we note in particular the changes in the meridional  
513 wind for the dynamic effect and the latent heat associated with the warming of the equatorial  
514 Atlantic for the thermodynamic effect.

## 515 **6 Summary and concluding remarks**

516 West Central Africa was hit by unprecedented exceptional rainfall in October 2019. A few  
517 studies have investigated the meteorological causes associated with these extreme rainfall events  
518 (Wainwright et al, 2020; Nicholson et al. 2022). This study followed these perspectives and focused  
519 on evaluating the dynamic and thermodynamic processes that controlled the extreme events of  
520 2019. We proceeded by decomposing the water balance and MSE equation, separating the  
521 associated dynamic and thermodynamic effects. Changes in atmospheric circulation are behind  
522 dynamic processes, while changes in water vapor are behind thermodynamic processes. This  
523 approach provides a better understanding of the mechanisms behind rainfall anomalies.. The main  
524 findings can be summarised as follows:

- 525 1. The main feature of October 2019 in the northern part of the area was a strong southerly  
526 circulation compared with the typical climatology for 1988-2017. In addition, a more  
527 pronounced rate of humidity associated with significant diabatic heating over West Central  
528 Africa up to 15°N was recorded.
- 529 2. The diagnosis of the water balance reveals that the exceptional rainfall in October 2019 was  
530 mainly dominated by dynamic effects. However, moisture advection induced by horizontal  
531 wind anomalies is the dominant process of precipitation anomalies over the northern part of  
532 the zone, while vertical moisture advection induced by vertical velocity anomalies is the  
533 dominant process of precipitation extremes in the south, mainly over Gabon and southern  
534 Congo Brazzaville. Changes in the thermodynamic effect, although not the key factor  
535 responsible for the events of October 2019, contribute up to 35% of the total effect (the sum  
536 of the dynamic and thermodynamic contributions) on the northern part and 15% on the  
537 southern part of the domain. The contribution of evaporation remains weak in both areas  
538 combined, which allows us to conclude that evaporation was not responsible for the heavy  
539 rainfall of October 2019 in West Central Africa.

540 3. The MSE vertical advection anomaly is dominated over the northern part of the area by the  
541 dynamic term (i.e. the advection of the wet enthalpy induced by the horizontal wind  
542 anomalies) compared to the thermodynamic terms (i.e. the horizontal advection of the MSE  
543 induced by the variation of the wet enthalpy and the vertical advection of the MSE induced  
544 by the variation of the MSE). In the southern part, the increase in the net energy balance  
545 compared with the climatology is the dominant process that has contributed most to the  
546 change in the structure of the vertical anomaly of the MSE. The prevailing net balance is  
547 controlled by the anomalies in radiative flux compared with the anomalies in latent and  
548 sensible heat flux. An extended analysis shows that these variations in the MSE over the  
549 north of West Central Africa were governed by its meridional component, in particular the  
550 variations in the meridional wind in the dynamic effect and the meridional variations in  
551 latent heat in the thermodynamic effect. It should be pointed out that in both cases, the  
552 contribution of dry enthalpy helped to reduce the dynamic term and was small in the  
553 thermodynamic term.

554 The results of this study show that moisture advection induced by horizontal wind anomalies and  
555 vertical moisture advection induced by vertical velocity anomaly were crucial mechanisms in the  
556 anomalous October 2019 exceptional rainfall increase over West Central Africa. In addition,  
557 changes in the MSE budget, mainly through the meridional circulation (dynamic effect), and latent  
558 heat (thermodynamic effect) also played an important role in the northern part of the area, while the  
559 increase in the energy balance contributed considerably to the change in the MSE balance in the  
560 southern part of the area. However, there was little contribution from dry enthalpy. These results are  
561 consistent with those of Nicholson et al (2022) who showed that the increase in equatorial Atlantic  
562 SSTs associated with the late retreat of the West African monsoon played an important role in  
563 precipitation anomalies in the Sahel. Changes in SSTs along the east coast of the equatorial Atlantic  
564 display a similar pattern to the Atlantic Niño as described by Lutz et al. (2013). Furthermore,  
565 Vallès-Casanova et al (2020) also highlighted the fact that 2019 was characterised by a particularly  
566 intense Atlantic Niño, which lasted until October, placing the dynamic and thermodynamic  
567 processes in the context of the large-scale circulation. The importance of the dynamic contribution  
568 during extreme precipitation events has been reported in other regions, notably over southern China  
569 (Wen et al. 2022; Sheng et al. 2023). This calls for comprehensive evaluations of both dynamic and  
570 thermodynamic contributions, and their possible feedback, to assess the potential impact of climate  
571 change on extreme precipitation events in this region.
