1 Introduction

This document can be regarded as a kind of lab notebook for an analysis of precipitation. It shows the merits of two key parameters, *the wet-day frequency* f_w and *wet-day mean precipitation* μ (also referred to as the ‘mean precipitation intensity’), and is meant to facilitate an open and transparent process that can be readily replicated by others.

This document is an R-markdown script written for empirical-statistical downscaling of probabilities and statistical properties of heavy 24-hr precipitation in the Nordic countries, based on Benestad et al. (2019). The R-code and results provided herein show how statistical properties of daily precipitation can be estimated based on f_w and μ according to $Pr(X > x) = f_w \exp(-x/\mu)$. This script may be adapted to repeat the analysis for other regions of the world.

The white-paper of Euro-CORDEX (<https://cordex.org/wp-content/uploads/2022/08/White-Paper-ESD.pdf>) recommends combining empirical-statistical downscaling (ESD) and dynamical downscaling with regional climate models (RCMs), as these two approaches are based on different assumptions and have different strengths and weaknesses. Nevertheless, this study only involves ESD, as its purpose is to demonstrate how ESD can be used to downscale various statistics for 24-hr precipitation and provide information that may be useful for decision-making and climate change adaptation. This is also meant to be a contribution to CORDEX-ESD and Euro-CORDEX.

This work is meant to provide a basis for the report ‘*Klima i Norge 2100*’ as well as preparing the ground for studying the connection between climate change and diarrhoea in the project EU-SPRINGS. It builds on the legacy of the projects KlimaDigital <https://www.sintef.no/projectweb/klimadigital/>, funded by the Norwegian Research Council (2018-2021), and EU-SPECS (FP7; 2012-2017).

1.1 Set-up: practical and technical considerations

This R-script saves intermediate results in temporary files (saved as R-binary data files `*.rda`) since some of the processing takes long time. It will look for these files and use them for the running of the script, but if they are not found, it will run through the original computations. The temporary files will be saved together with this R-markdown script for the benefit of those who want to replicate this analysis.

## Package: esd
## Version: 1.10.79
## Date: 2024-04-29
## Title: Climate analysis and empirical-statistical downscaling (ESD)
##         package for monthly and daily data
## Author: Rasmus E. Benestad, Abdelkader Mezghani, Kajsa M. Parding,
##         Helene B. Erlandsen, Ketil Tunheim, and Cristian Lussana
## Maintainer: Rasmus E. Benestad <rasmus.benestad@met.no>
## Depends: R (>= 4.00.0), ncdf4, zoo
## Imports: graphics, grDevices, stats, utils
## Suggests: LatticeKrig, fields, PCICt, jpeg, jsonlite
## Description: The package contains R functions for retrieving data,
##               making climate analysis and downscaling of monthly mean and
##               daily mean global climate scenarios.

1.2 Settings for downscaling

The choice of predictor domain used for the downscaling was set to match that used for evaluating the model results, shown at the end of this R-markdown script.

The evaluation shown near the end of this R-markdown script reveals an outlier: CESM2-WACCM-FV2. We exclude it from the projections, even if the ensemble itself is getting a bit small.

```

recompute <- FALSE
## The region of predictors from GCMs evaluated at the end of this R-markdown script
regions <- "-5-45E.55-72N"
## Runs which caused the running of the code to crash - to be excluded
bad.runs <- c("EC-E", "FGOA", "IPSL", "KACE", "MPI-", "UKES")
outlier.runs <- c("CESM")
## Define the spatial domain for the predictor: same as the domain used for evaluation
## of CMIP6 GCMs.
lons <- c(-5, 45)
lats <- c(55, 72)

```

1.3 Preprocessing ERA5 24-hr precipitation

The ERA5 data (Hersbach and Dee (2016)) was downloaded from the Copernicus Climate Services (C3S) climate data store (CDS) site using `esd::ERA5.CDS()`:

```
ERA5.CDS(param='total_precipitation', varnm='tp', FUN='daysum')
```

The daily global ERA5 data was then aggregated into wet-day frequency f_w and wet-day mean precipitation μ (the threshold for a wet day was 1 mm/day):

```

## R-script to estimate wet-day mean and wet-day frequency from ERA5/EOBS.
## Rasmus Benestad 2023-05-26

clean <- TRUE

## This routine masks the data wet/dry and estimates monthly wet-day frequency
## and mean precipitation intensity
wetdaymean <- function(ifile, datadir, outdir) {
  ## Make sure that all files have the same longitude/latitude setting as the first file
  print('Ensure correct grid - use the grid from ERA5_tp_1940_daysum.nc')
  system(paste0('cd0 -b f32 remapcon,', file.path(datadir, 'ERA5_tp_1940_daysum.nc '),
               file.path(datadir, ifile), ' out.nc'))
  print('Make mask of precipitation')
  system('cd0 gtc,0.001 out.nc mumask.nc')
}

```

```

## The file mumask.nc is a mask with 0.001 (m) in all time steps with exceeding
## data (set to 1) and 0 for all others
system(paste('cdo ifthen mumask.nc out.nc masked.nc'))
## her appliseres masken på ifile og lagres i ofile. (Øvrige punkter får verdien NA.)
system(paste('cdo monmean masked.nc',file.path(outdir,sub('daysum.nc','mu.nc',ifile))))
system(paste('cdo monmean mumask.nc',file.path(outdir,sub('daysum.nc','fw.nc',ifile))))
system(paste('cdo -fldmean masked.nc',file.path(outdir,sub('daysum.nc','TP.wet.nc',ifile))))
file.remove('mumask.nc')
file.remove('masked.nc')
file.remove('out.nc')
}

## Setup
print('Generate the statistics...')
datadir <- '~/data/ERA5/day'
outdir <- '~/Downloads/ERA5-precip-statistics'
old.files <- NULL
if (!exists(outdir)) dir.create(outdir) else {
  old.files <- list.files(path=outdir,full.names = TRUE)
  if (clean) file.remove(old.files)
}

## Save temporary files if the job is not completed...
print('Monthly wet-day-mean and wet-day frequency for each year...')
files <- list.files(path=datadir,pattern='_tp_')
if ((!is.null(old.files)) & (!clean) ) {
  donefiles <- sub('/home/rasmusb/Downloads/ERA5-precip-statistics/ERA5_tp_','','',
                  old.files[grep('TP.wet.nc',old.files)])
  donefiles <- sub('_TP.wet.nc','','',donefiles)
  files <- files[-match(donefiles,sub('_daysum.nc','','',sub('ERA5_tp_','','',files)))]
}
print(files)

for (file in files) {
  print(file)
  wetdaymean(file,datadir,outdir)
}
file.remove(file.path(outdir,"first.ERA5grid.nc"))

## Merge the annual files
print('Merge the results')
results <- list.files(path=outdir,pattern='mu.nc',full.names = TRUE)
system(paste('cdo mergetime',paste(results,collapse=' '),
            file.path('~/Downloads/','ERA5_mu_mon.nc')))
file.remove(results)
results <- list.files(path=outdir,pattern='fw.nc',full.names = TRUE)
system(paste('cdo mergetime',paste(results,collapse=' '),
            file.path('~/Downloads/','ERA5_fw_mon.nc')))
file.remove(results)
results <- list.files(path=outdir,pattern='TP.wet.nc',full.names = TRUE)
system(paste('cdo mergetime',paste(results,collapse=' '),
            file.path('~/Downloads/','ERA5_TP.wet.nc')))
file.remove(results)

```

```

## Make annual aggregation
system('cdo yearavg ~/Downloads/ERA5_fw_mon.nc ~/Downloads/ERA5_fw_year.nc')
system('cdo yearavg ~/Downloads/ERA5_mu_mon.nc ~/Downloads/ERA5_mu_year.nc')

```

The subsequent analysis and downscaling relied on aggregated daily ERA5 data processed as described above.

2 Downscaling

Annual local wet-day frequency f_w and wet-day mean precipitation μ were downscaled using f_w and μ respectively to represent the *large-scale predictors*, as shown below. The annual aggregates were used here as a starting point of this kind of analysis, but it may potentially be extended to seasonal statistics to capture aspects that may be stratified in terms of seasons. Extending this analysis to seasonal statistics will increase the volume of results and result in longer scripts and documents.

The predictors were based on ERA5 for calibration and daily precipitation from CMIP6 global climate models (GCMs; Eyring et al. (2015)) for projections. The Downscaling used common EOFs as framework, as explained in the discussion paper Benestad (2021). The common EOF framework provides an additional level of evaluation and quality control in addition a better way to combine GCM output and reanalysis.

```

ssps <- list.files(path='data/CMIP/CMIP6.monthly/wet-day-frequency/')
ssps <- ssps[grep('ssp|hist',ssps)]

To check the results, we plotted maps of the predictors from ERA5. The mean f_w indicated higher values near the western coasts of Norway, as expected. The results of an empirical orthogonal function (EOF) analysis of f_w from the ERA5 reanalysis also indicated pronounced variability over the ocean and in the north. The leading EOF accounted for 30% of the variance and the leading 20 EOFs represented 88% of the total variance. The second EOF accounted for 19% of the variance and represents an important part of the variability.

For the downscaling exercise based on ERA5 only, we took a random sample - in this case Oslo-Blindern. The downscaled results for f_w gave a good and close match between historical observations and downscaled f_w using f_w from ERA5 as predictor. The same exercise and evaluation for μ also indicated a match, but not as good as for f_w . Moreover, downscaled μ based on ERA5 μ underestimated the observed trend since 2000. In both cases, there was an upward trend in annual f_w and μ , both being significant at the 5%-level.

2.0.1 The predictand - aggregated rain gauge measurements

The chunk above shows a map with all the station coordinates with colour coded elevation. The predictand spanned the time interval 1950-2023, ad covered longitudes between 5-30E, latitudes 55-71N and elevations 0m - 2062m.

The predictand was represented in terms of principal component analysis (PCA) results of annual f_w estimated from the rain gauge data from ECA&D (Klein Tank et al. (2002)), as grouping the station data through PCA seems to increase the signal-to-noise ratio (Benestad and Mezghani (2015)). The spatial pattern of the matches between the predictand and predictor for PC 1 indicated similar geographical weights and the cross-validation gave a strong match with correlation of 0.93. The calibrated model managed to reproduce most of the observed interannual variability in PC#1 for local f_w in the Nordic countries. Corresponding results for the second EOF gave a cross-validation correlation of 0.92.

The map of mean μ also indicate higher values near the coast and the leading EOF accounts for 19% of the variance. The 20 leading EOFs account for 74% of the total variance, suggesting that the wet-day mean precipitation has stronger presence of small-scale variability. The second EOF explained 9%, and the higher order modes (not shown) also contributed to the variability.

A downscaling exercise based only on annual μ from ERA5 and rain gauges also gave a good match between the predictor and predictand: similar geographical weights and a cross-validation correlation of 0.96. The second EOF for μ explained 8% of the variance. For the second mode, the cross-validation correlation was 0.81, connected to geographical weights along the coast of Norway.

There was a good match between precipitation statistics aggregated from rain gauge measurements and the ERA5 reanalysis.

In other words, the results of the downscaling indicate that both f_w and μ to a large extent can be estimated based on their respective large-scale equivalents from the ERA5 reanalysis. There is, however, a question whether the GCMs are able to skillfully reproduce the same large-scale features in f_w and μ , and an evaluation of their skill is provided at the end of this R-markdown script.

2.1 Diagnostics of the results

The following chunk provides information of 652 locations with rain gauge data downscaled and a model ensemble originally with 30 members used here to estimate future local climate projections. Some of the members were removed due to data issues resulting in technical crash when running the code. Also, one suspect member identified from the GCM evaluation was removed from the projection of future rainfall statistics.

The results can also be inspected by showing the time series for one location, in this case Oslo and the SSP370 emission scenario.

2.1.1 Historical statistics f_w and μ

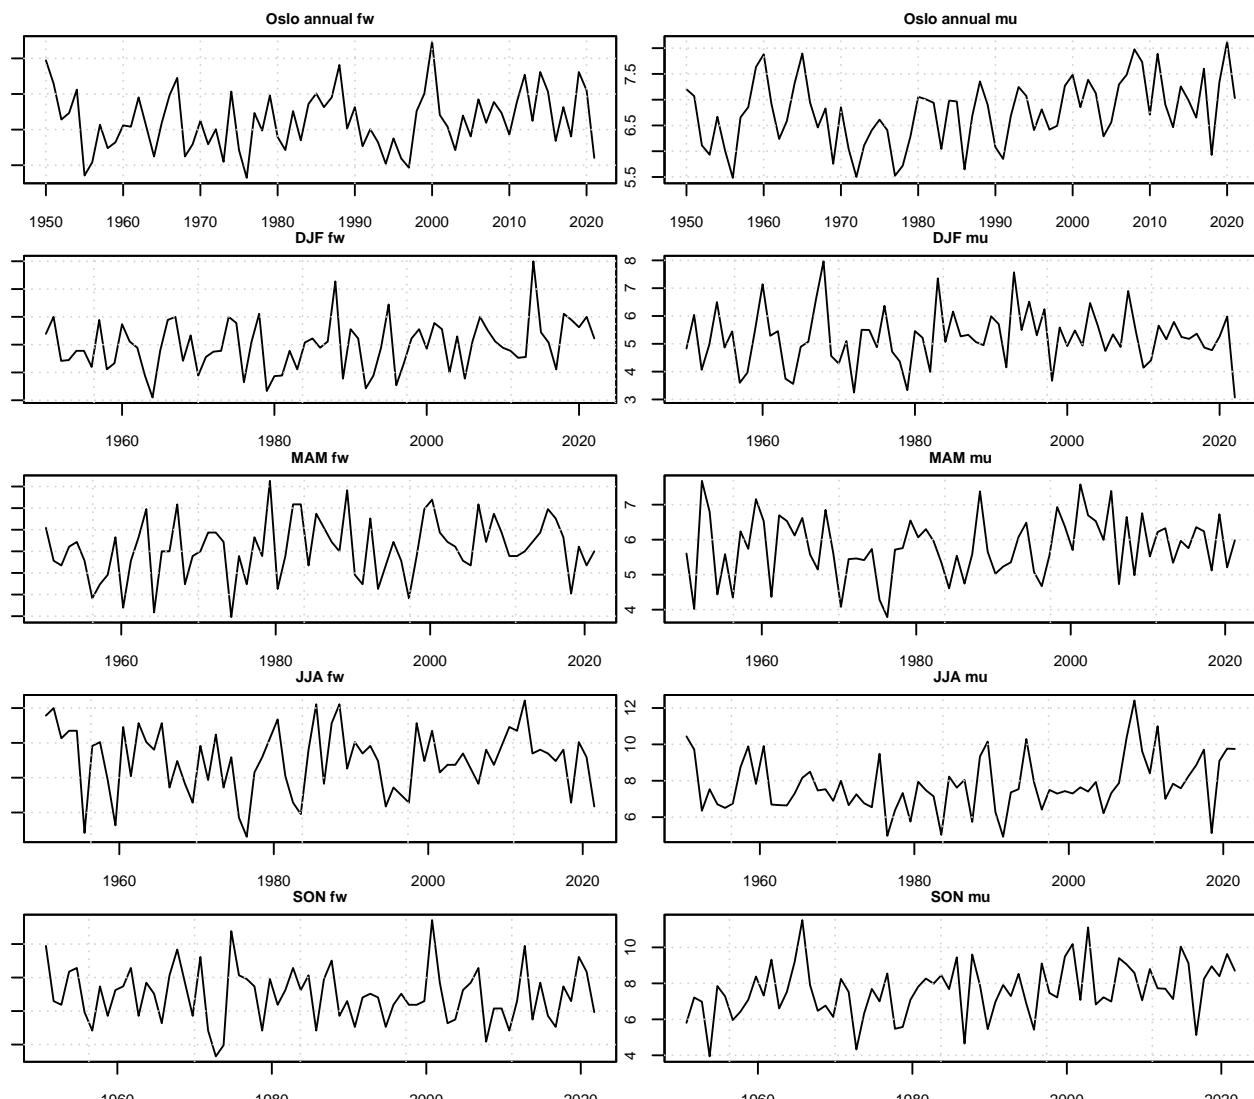

Since the trend in the annual mean may mask seasonally differing trends, it's instructive to examine trend estimates for the historical data. Below, this is illustrated for Oslo but also statistics are presented for all sites with long time series (more than 20.000 valid data points).

```
oslo <- subset(Y, loc='OSLO BLINDERN')
layout(matrix(1:10,5,2))
par(mar=c(1.5,1,1.5,1),cex.lab=0.7,cex.axis=0.7,cex.main=0.7)
```

```

## Wet-day frequency
plot(zoo(annual(oslo,FUN='wetfreq')),main='Oslo annual fw'); grid()
plot(zoo(subset(as.4seasons(oslo,FUN='wetfreq'),it='djf')),main='DJF fw'); grid()
plot(zoo(subset(as.4seasons(oslo,FUN='wetfreq'),it='mam')),main='MAM fw'); grid()
plot(zoo(subset(as.4seasons(oslo,FUN='wetfreq'),it='jja')),main='JJA fw'); grid()
plot(zoo(subset(as.4seasons(oslo,FUN='wetfreq'),it='son')),main='SON fw'); grid()
## Wet-day mean precipitation
plot(zoo(annual(oslo,FUN='wetmean')),main='Oslo annual mu'); grid()
plot(zoo(subset(as.4seasons(oslo,FUN='wetmean'),it='djf')),main='DJF mu'); grid()
plot(zoo(subset(as.4seasons(oslo,FUN='wetmean'),it='mam')),main='MAM mu'); grid()
plot(zoo(subset(as.4seasons(oslo,FUN='wetmean'),it='jja')),main='JJA mu'); grid()

```

The analysis of historical data suggests that there has been mainly increases in the wet-day frequency f_w , albeit weak. Most pronounced increases are seen in winter (DJF). The map suggests that there is a weak increase in annual f_w in general over the Nordic region.

The analysis of historical observations also suggest a majority of locations with increasing wet-day mean precipitation μ for the annual mean as well as most seasons. The map showing trends in annual μ suggest a general historical increase in intensity over the Nordic region.

2.1.2 Simulations: f_w and μ

Note, the different parameters f_w and μ and emission scenarios (HIST/SSPs) involve somewhat varying sets of GCMs.

The following R-code chunk presents multi-model ensembles downscaled annual f_w and μ for Oslo for the historical run (“HIST”) and future projections (“SSPs”).

```
## The allN function extracts the time interval for which the ensemble has valid
## data for all its members
allN <- function(x,verbose=FALSE) {
```

```

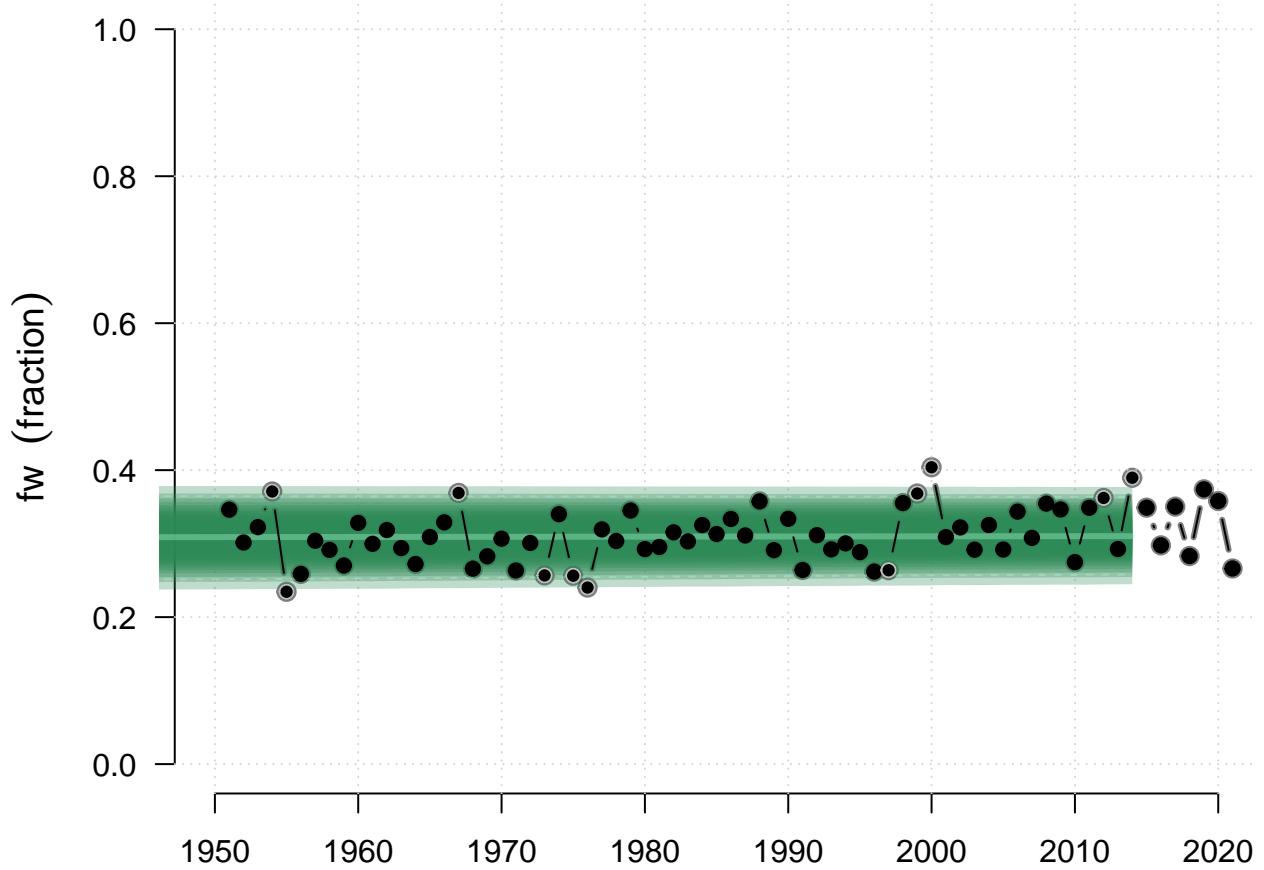

## Remove members with short time span
nt <- length(index(x))
cls <- class(x)
if (verbose) {print('Remove members with short time span:'); print(dim(x))}
nv <- apply(coredata(x), 2, FUN='nv')
if (verbose) print(nv)
im <- nv >= quantile(nv, probs = 0.75)
x <- subset(x, im=im, verbose=verbose)
## Remove times with incomplete ensemble
if (verbose) {print('Select interval with completness ensemble:'); print(dim(x))}
nv <- apply(coredata(x), 1, FUN='nv')
if (verbose) print(nv)
it <- nv==max(nv, na.rm=TRUE)
y <- subset(x, it=it, verbose=verbose)
y <- attrcp(x, y)
class(y) <- cls

```

Oslo: mean precipitation intensity: SSP585

The results for the historical runs indicated that the downscaled ensemble generally span the observed annual f_w (black symbols) tightly, but μ is low biased because it uses a climatology defined for the whole period of observations and there is a historical upward trend in μ .

The local projection based on SSP370 indicated that no clear future trend in f_w , which is consistent with the past. For μ , there is a slight increasing tendency and there has been a long-term increase in the observations (black symbols). The downscaled results seem to underestimate the magnitude of the long-term trend, judging from the historical trend (HIST and SSP370), but the projections for μ connected to SSP585 indicated more a pronounced long-term trend.

The length of the scenario projections was determined by the availability of all members within the ensemble. Some models dropped out after 2050, and changes in the ensemble sample gave misleading impressions. The results for SSP245 for μ suffered from small ensemble size.

The downscaled μ for SSP126 were spurious, indicating that there may have been a data issue, most likely with the extracted information from the CMIP6 GCMs.

2.1.3 Table of selected station projections

```

```

2.2 Is the ensemble normally distributed?

It's useful to check if the Oslo results $x \sim \mathcal{N}(\mu, \sigma^2)$, because the information embedded in an ensemble with normally distributed members can be quantified in terms of the ensemble mean and standard deviation. The test for normal distribution was only applied to the interval when all ensemble members had valid data.

Oslo: Wet-day mean precipitation SSP585

The results for μ also indicated that the distribution of ensemble members was close to a normal distribution, but there was one exception for the data points at the high end in SSP585. Hence, the ensemble results for μ were reasonably close to being normally distributed.

This means that the range of downscaled results can be approximated according to $x \sim \mathcal{N}(\mu, \sigma^2)$.

2.2.1 Individual ensemble members

The chunk below shows the individual members of the ensemble, revealing that two members of SSP126 and the SSP585 members go all the way to year 2300 whereas most stop in 2100. There is little tendency of clustering and the results suggest that the ensemble members behave more or less in a similar way (after bad runs were precluded).

2.4 Local 24-hr precipitation statistics and heavy precipitation

The following chunk reads the original daily precipitation saved as a temporary file and extracts data for Oslo which will be used in the following exercises.

The R-chunk below tests the rain equation against observations for Oslo daily rainfall:

```
y <- subset(Y, is=loc(fw.oslo.ssp370))
z <- test.rainequation(y)
```

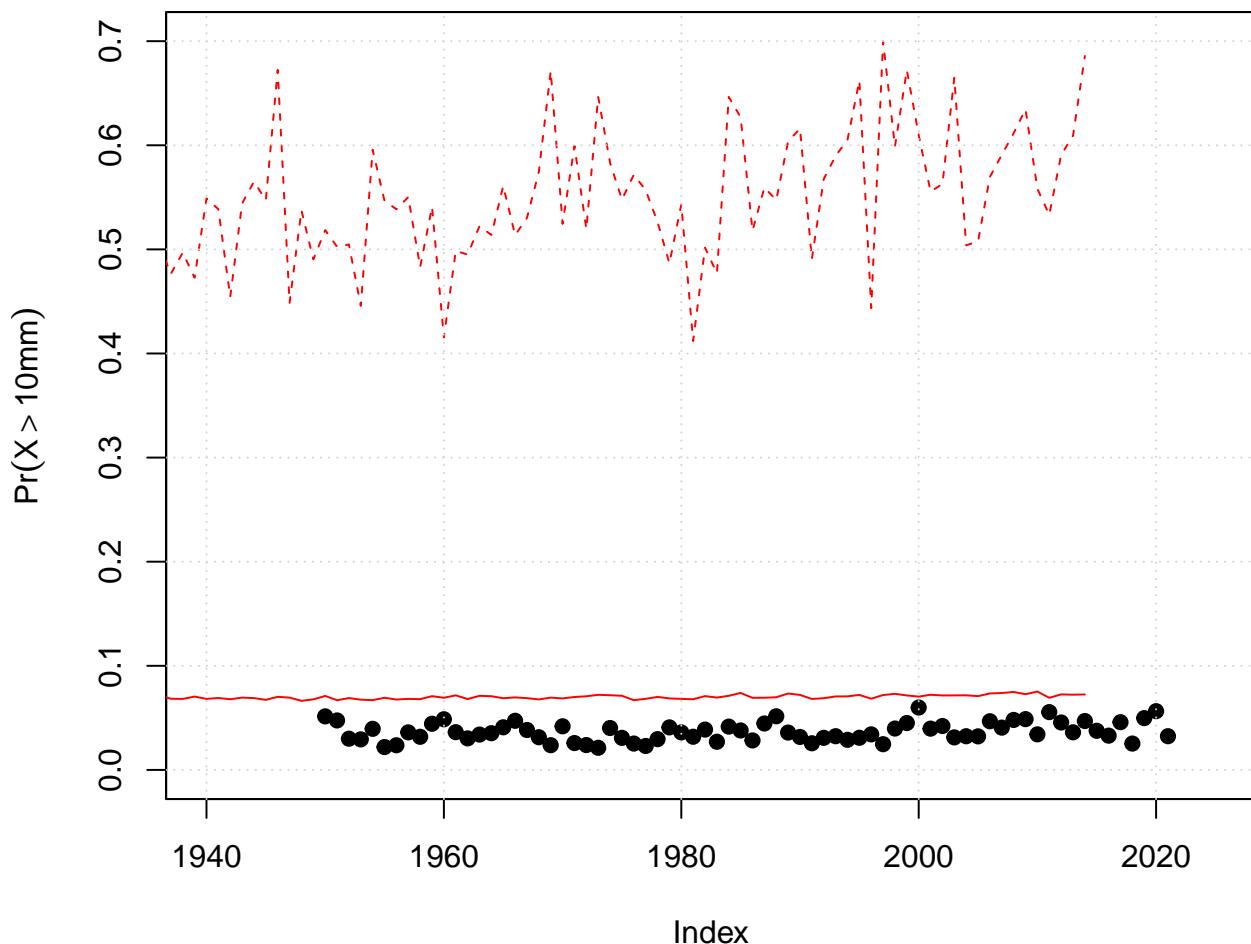

Although the match is not perfect, there is a clear correlation between the estimated probability (black curve) and the fraction of days with precipitation exceeding 20 mm/day (red curve).

We can compare the rain equation from observations with the downscaled results from HIST:

```
m.x10 <- zoo(FW.mean.hist*exp(-10/MU.mean.hist),order.by=index(fw.oslo.hist))
s.x10 <- zoo(
  sqrt( (FW.std.hist*exp(-10/MU.mean.hist)/FW.mean.hist*exp(-10/MU.mean.hist))^2 +
    (FW.mean.hist*exp(-10/MU.mean.hist)/FW.std.hist*exp(-10/MU.mean.hist))^2 ),
  order.by=index(fw.oslo.hist))
plot(m.x10,main='Oslo: Fraction of days with more than 10 mm precipitation',
  ylab=expression(Pr(X > 10*mm)),col='red',xlim=c(1940,2025),
  ylim=c(0,max(m.x10+s.x10,na.rm=TRUE)))
lines(m.x10+s.x10,lty=2,col='red')
lines(m.x10-s.x10,lty=2,col='red')
points(rainequation(y,threshold=10),pch=19)
grid()
```

Oslo: Fraction of days with more than 10 mm precipitation

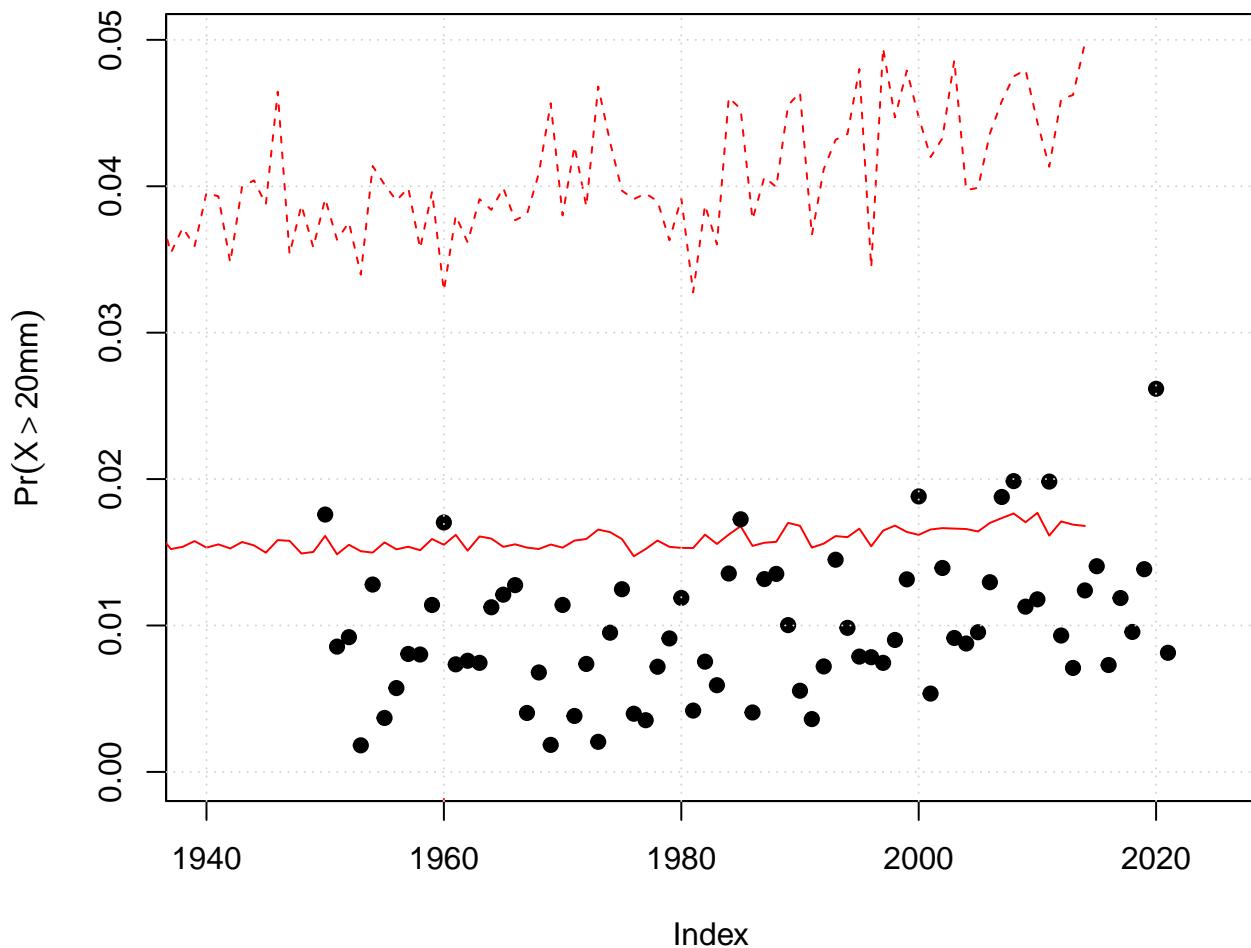

A comparison between the probability of days with more than 21 mm precipitation from the historical ensemble of downscaled f_w and μ (solid curve shows ensemble mean and dashed curves indicate the ensemble mean plus/minus one standard deviation) gave a good match with the general level observed numbers (symbols), although the predicted ensemble was systematically higher than the observations.

```

m.x20 <- zoo(FW.mean.hist*exp(-20/MU.mean.hist),order.by=index(fw.oslo.hist))
s.x20 <- zoo(
  sqrt( (FW.std.hist*exp(-20/MU.mean.hist)/FW.mean.hist*exp(-20/MU.mean.hist))^2 +
    (FW.mean.hist*exp(-20/MU.mean.hist)/FW.std.hist*exp(-20/MU.mean.hist))^2 ),
  order.by=index(fw.oslo.hist))
plot(m.x20,main='Oslo: Fraction of days with more than 20 mm precipitation',
     ylab=expression(Pr(X > 20*mm)),col='red',xlim=c(1940,2025),
     ylim=c(0,max(m.x20+s.x20,na.rm=TRUE)))
lines(m.x20+s.x20,lty=2,col='red')
lines(m.x20-s.x20,lty=2,col='red')
points(rainequation(y,threshold=20),pch=19)
grid()

```

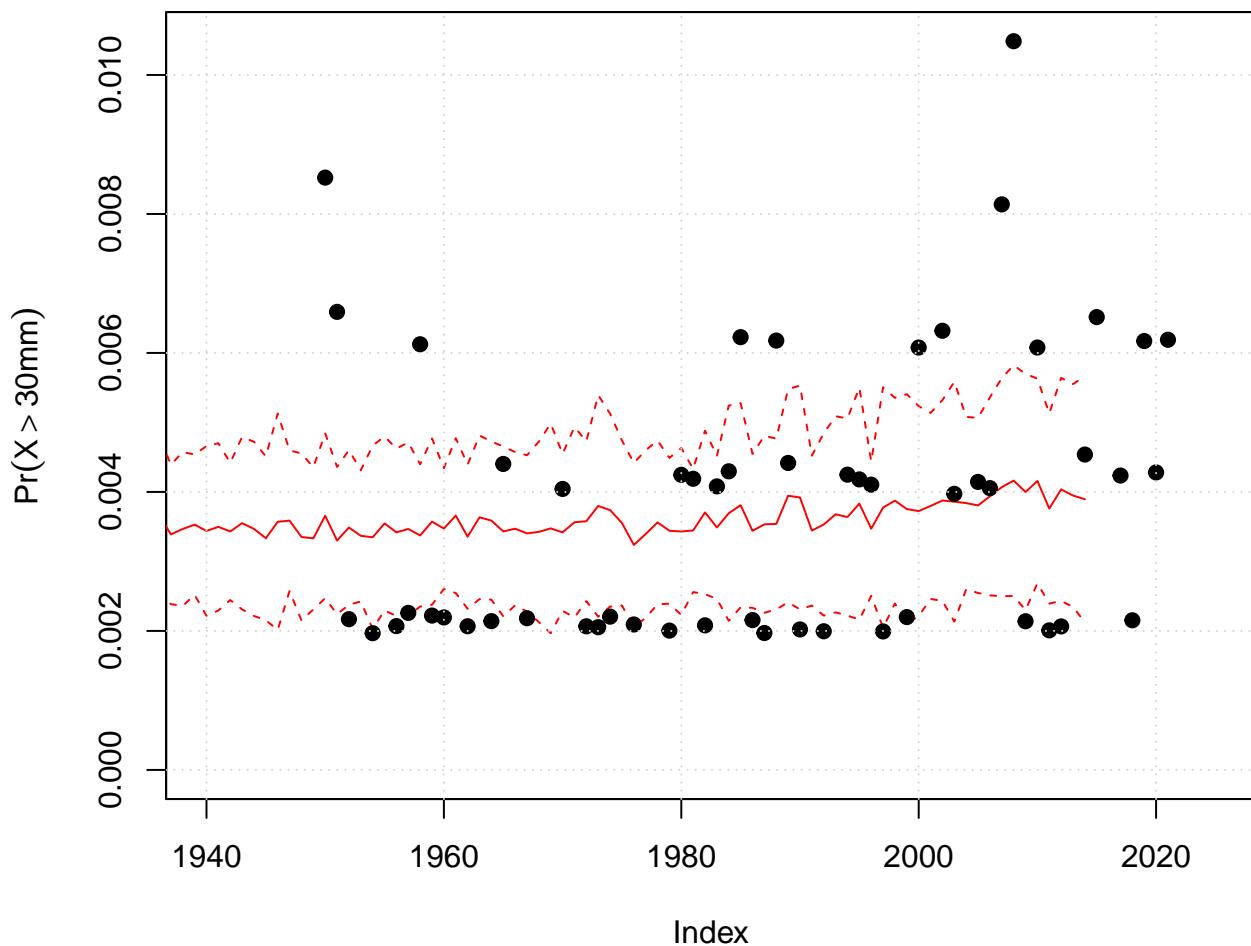

Oslo: Fraction of days with more than 20 mm precipitation

A comparison between the probability of days with more than 20 mm precipitation from the historical ensemble of downscaled f_w and μ (solid curve shows ensemble mean and dashed curves indicate the ensemble mean plus/minus one standard deviation) gave a good match with the general level observed numbers (symbols). Nevertheless, the downscaled ensemble spans a wider range of fractions than the observed interannual variations in the fractions.

```
m.x30 <- zoo(FW.mean.hist*exp(-30/MU.mean.hist),order.by=index(fw.oslo.hist))
s.x30 <- zoo(
  sqrt( (FW.std.hist*exp(-30/MU.mean.hist)/FW.mean.hist*exp(-30/MU.mean.hist))^2 +
    (FW.mean.hist*exp(-30/MU.mean.hist)/FW.std.hist*exp(-30/MU.mean.hist))^2 ),

Oslo: Fraction of days with more than 30 mm precipitation

The results for days with more than 30 mm precipitation also agreed well with the observations.

2.5 Intensity-Duration-Frequency (IDF) analysis

We can aggregate the ensemble and use its statistics to estimate intensity-duration-frequency (IDF) curves for selected locations according to Benestad et al. (2020): $x_\tau = \alpha\mu(L/24)^\zeta \ln(f_w\tau)$. We used data-frames and aggregation to estimate intensity-duration-frequency (IDF) curves for the ensemble mean as well as selected quantiles of the ensemble distribution.

The shape of the IDF curves are expected to reflect the presence and severity of various meteorological phenomena that generate precipitation: e.g. convection, cyclones, frontal systems, atmospheric rivers. It is not certain that all of them are skilfully reproduced by GCMs, but the information about their relative contribution to the total rainfall is embedded in the shape of these curves and derived semi-empirically.

```

Our comparison between IDF curves estimated from the SSP370 ensemble mean for the start and the end of the runs suggests similar scaling factors for different duration, as expected from the formulae used here ($\alpha\mu(L/24)^c \ln(f_w\tau)$). The scaling factors vary with the return interval, 1.13–1.14 for downscaled results for the SSP370 ensemble mean, but these figures may be somewhat conservative since f_w and μ are not entirely specified by the large-scale conditions and it doesn't include decadal variability. For SSP585, the scaling ratios are 1.27–1.38.

If we account for decadal variability, subtracting one ensemble spread standard deviation from the start and adding one standard deviation to the end, the scaling obtained for SSP370 is 1.18–1.20.

However, if the GCMs do not skillfully reproduce phenomena such as convection and frontal systems with sufficient realism, we can expect these estimates to be somewhat conservative.

2.5.1 PCA-based analysis?

An alternative approach is based on Parding et al. (2023) using PCA to represent the curves of the IDF curves and a regression analysis to link them to climatic parameters.

2.6 Downscaling number of wet-days directly

In addition to downscaling statistical parameters such as f_w and μ , it may be possible to estimate other types of statistical information such as probabilities or number of events directly.

The number of days is a discrete number and doesn't follow a normal distribution. For this reason, the analysis is focused on a single station rather than a group of stations, because PCA is designed to operate on the covariance matrix of continuous and normally distributed data. Single station series have lower signal-to-noise ratio than station groups represented in terms of PCA.

2.7 Examine droughts

Information about extremes such as drought can be quantified in terms of the probability of the duration of dry spells exceeding a given threshold. If the duration statistics approximately follows a geometric distribution, then a key parameter is the mean duration. Here is an example how the annual mean dry-spell duration is utilised in connection with an empirical-statistical downscaling exercise for Norway.

```

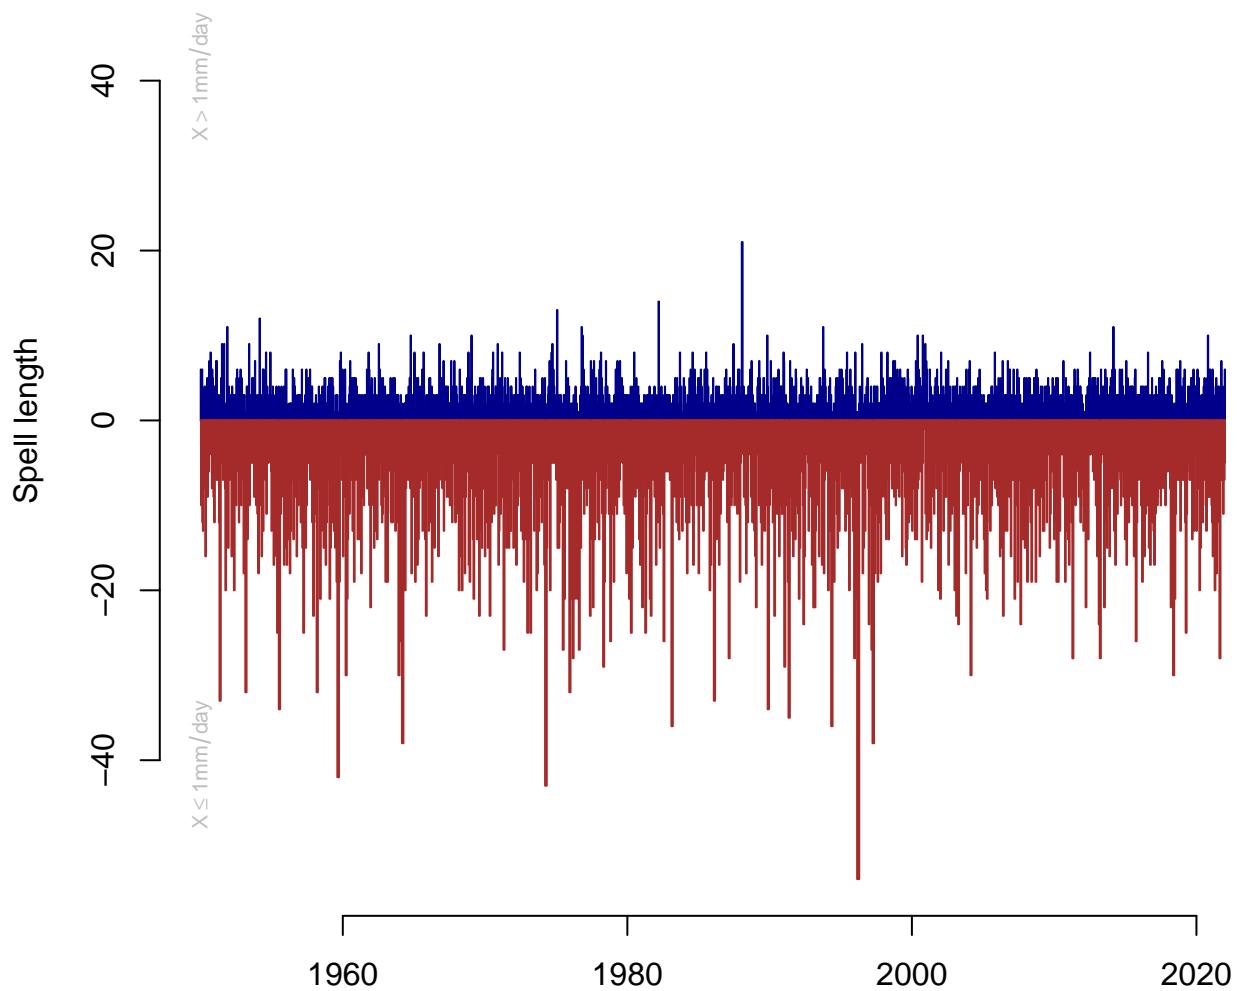

## Extract the spell length statistics of daily precipitation data from Oslo
## with a wet-day threshold of 1 mm/day.
s <- spell(y,threshold=1)

## Warning in min(missing): no non-missing arguments to min; returning Inf

```

```
plot(s,new=FALSE)
```

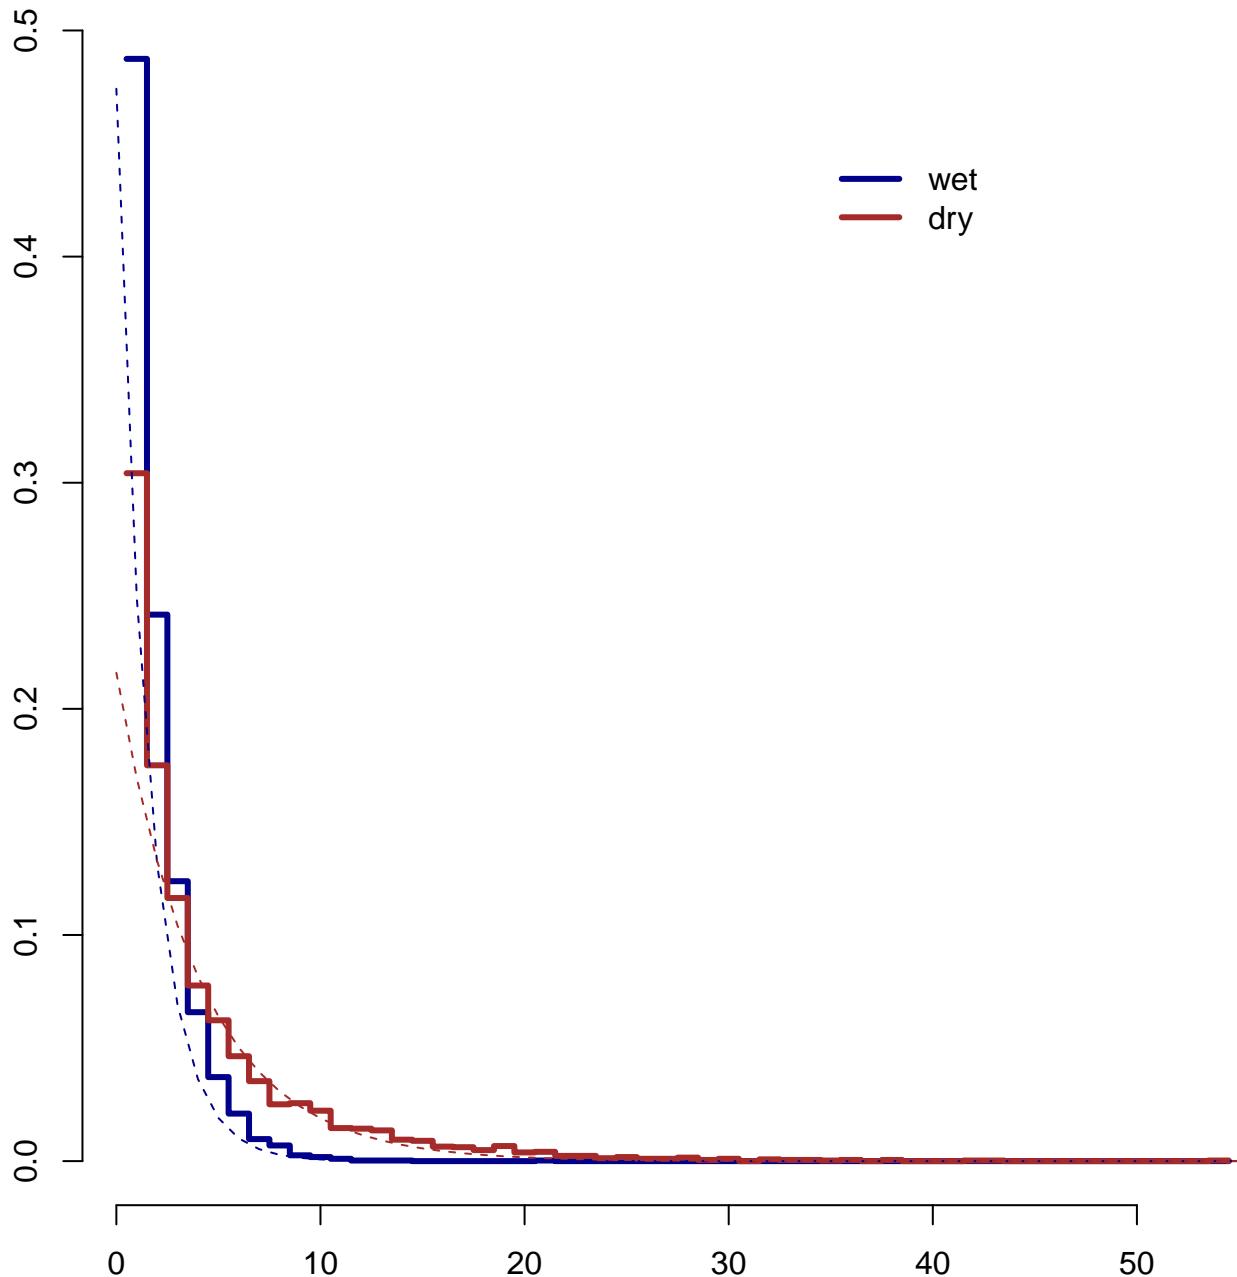

OSLO BLINDERN: wet and dry

```
## NULL
```

```
## Compare the statistics to a geometric distribution
par(mar=c(2,2,2,2))
hist(s,new=FALSE)
```

OSLO BLINDERN wet and dry spell duration

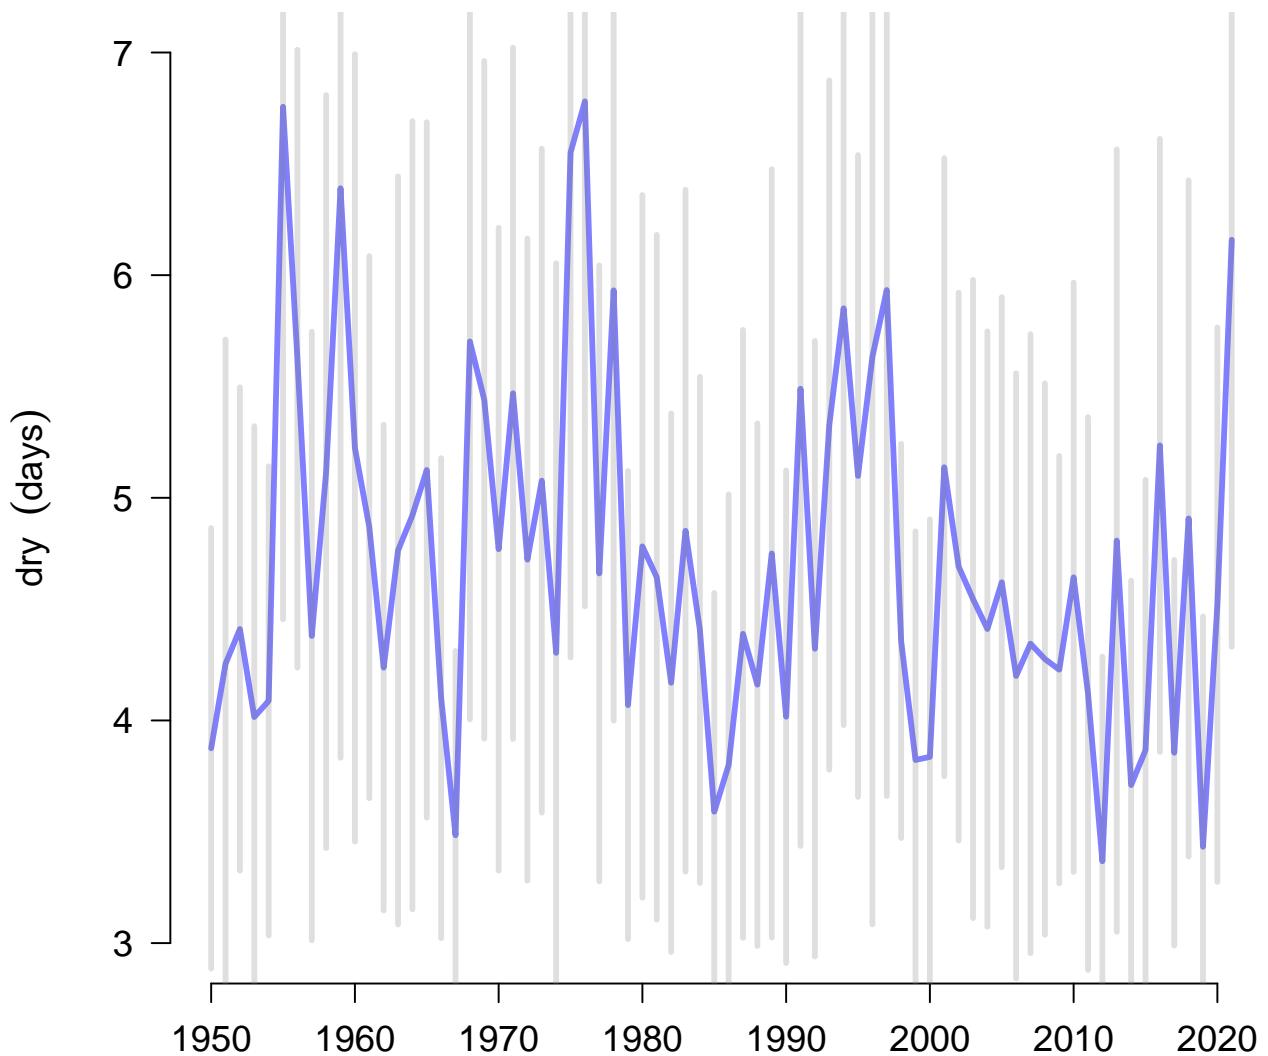

The duration statistics of wet and dry are shown above and the histogram compares their empirical distributions (solid) with the geometric distribution (dashed lines). The geometric distribution gives an approximate representation of the statistics, but there are some deviations for the shorter spells. for the geometric distribution $Pr(x = k) = (1 - p)^{k-1}p$, the success probability p is a key parameter and $k = [1, 2, 3, \dots]$ is the duration in days. The mean duration is $1/p$, and hence is the inverse of the parameter defining the shape of the distribution. Because of this, we seek the mean duration of dry spells to estimate the probability of droughts with a given number of successive number of dry days.

We can aggregate the dry spell duration statistics into the annual mean dry spell length and test whether it is related to the wet-day frequency on larger spatial scales. Below is an attempt for Oslo precipitation:

```
mean.dry <- annual(subset(s,is=2),FUN='mean',nmin=1)
plot(mean.dry,main='Oslo: Annual mean dry-spell duration',new=FALSE)
```

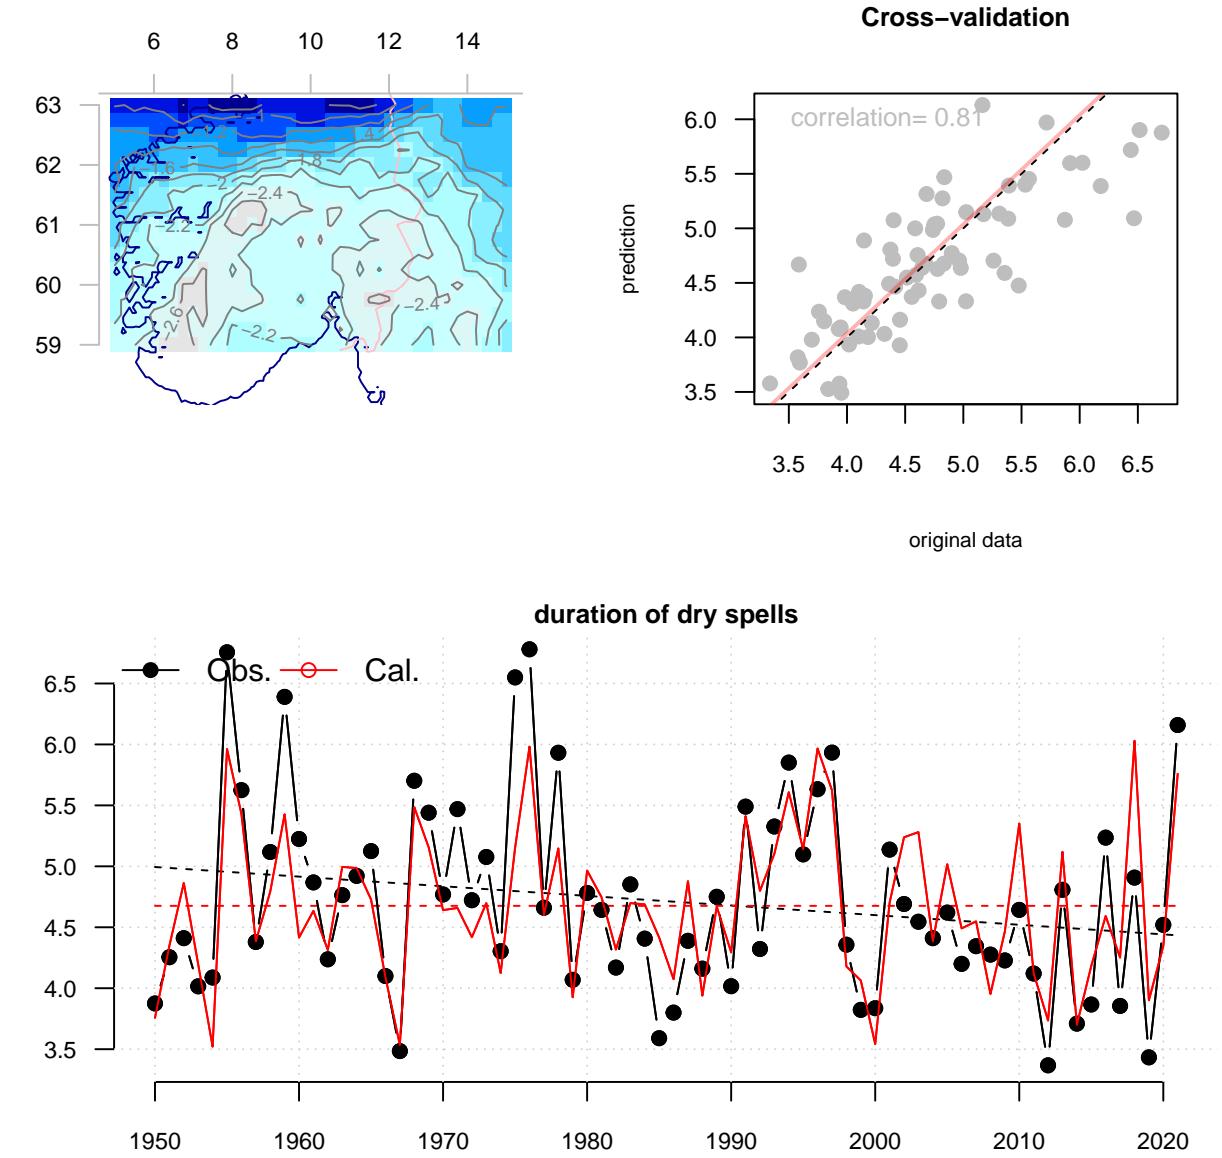

Oslo: Annual mean dry-spell duration

```
FW <- retrieve(~data/ERA5/ERA5_fw_year.nc, lon=c(5,15), lat=c(59,63))
```

```
## [1] "Warning : Frequency found in the attribute does not match the frequency detected in data"
```

```
index(FW) <- year(FW)
eof.fw <- EOF(FW)
attr(eof.fw, 'time') <- range(index(FW))
ds.dry <- DS(mean.dry,eof.fw,method = 'glm')
plot(ds.dry,new=FALSE)
```

The results from this exercise suggests that the mean duration approximately follows the large-scale wet day frequency f_w from the ERA5 reanalysis, which is not unexpected. The spatial pattern with low f_w for ERA5 in the vicinity of Oslo also supports this connection, although there are two local minima and none is exactly on top of Oslo.

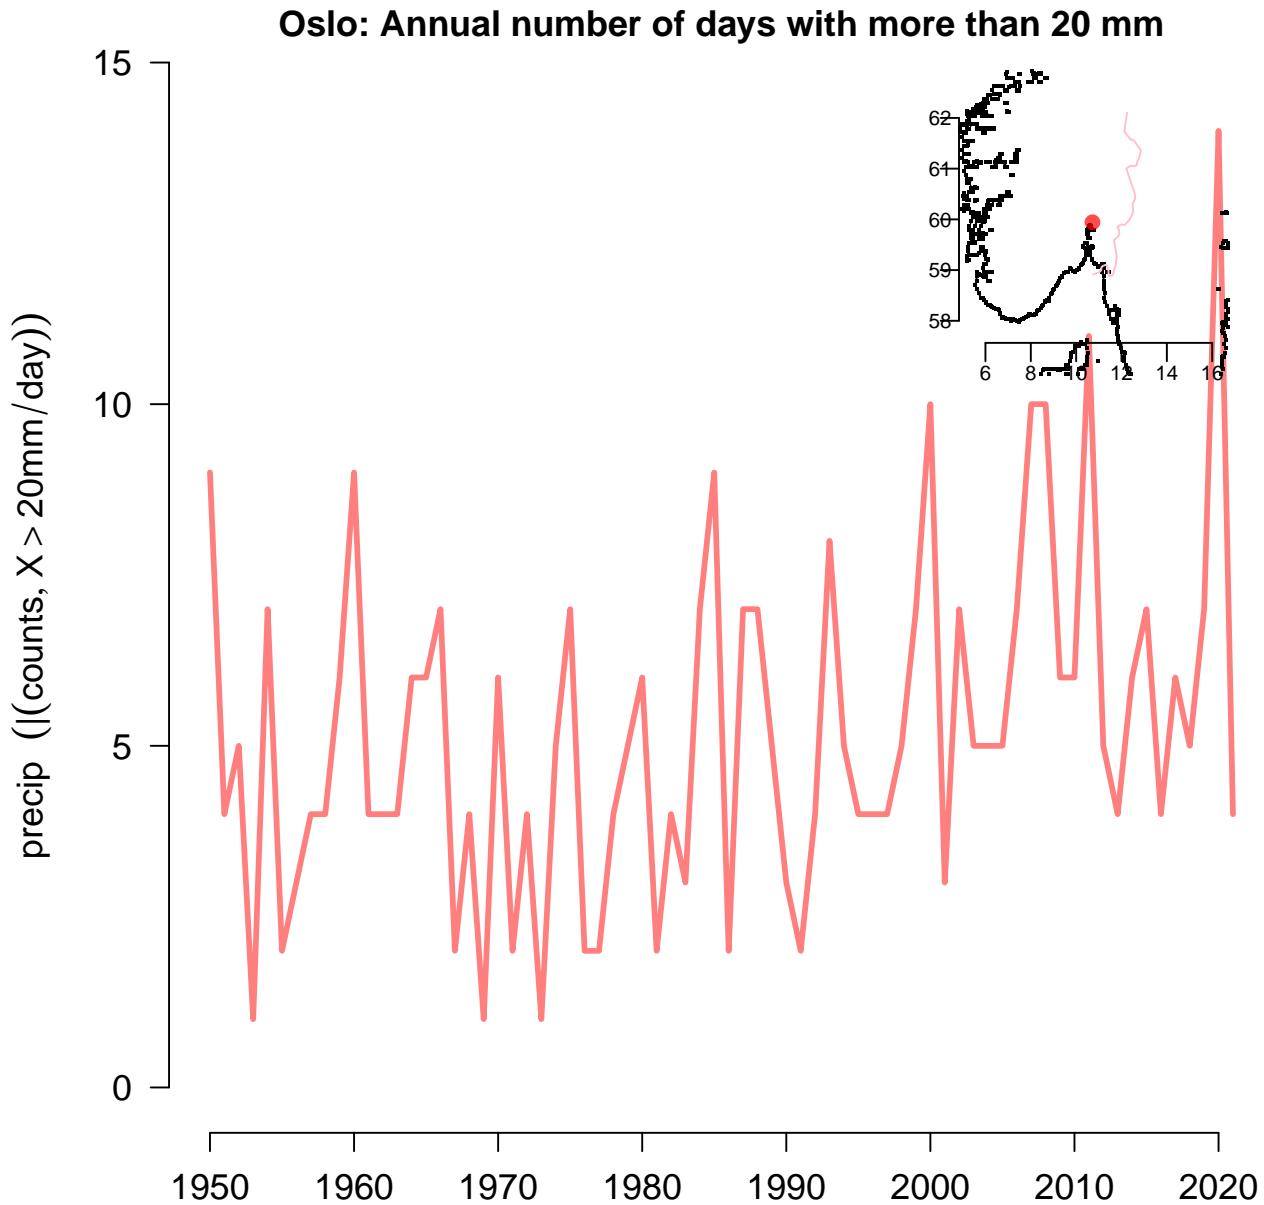

2.8 Examine the number of very wet-days

For the number of events, we can use a framework based on a stochastic process with Poisson distribution and a rate λ so that $Pr(X = k) = \frac{\lambda^k e^{-\lambda}}{k!}$. We can explore the predictor $n \propto f_w e^{-x/\mu}$ for different thresholds $x = [20, 21, \dots]$ to explore pattern and possibility for extrapolation. Test for Oslo. GLM.

One way to downscale information about extremes is to estimate the number of events over a period and assume that the number would follow a Poisson distribution if it were random. Here is an example with number of ‘very wet days’ (more than 20 mm/day) per year.

Here, we expect that the number of wet days follows a similar pattern as shown above with `test.rainequation` and a predictor derived through a transformation of both f_w and μ according to $Pr(X > x) = f_w \exp(-x/\mu)$:

```
nvwet <- annual(y, FUN='count', threshold=20, nmin=1)
plot(nvwet, main='Oslo: Annual number of days with more than 20 mm', new=FALSE)
```

```
MU <- 1000*retrieve('~/data/ERA5/ERA5_mu_year.nc', lon=c(5,15), lat=c(59,63))
```

```
## [1] "Warning : Frequency found in the attribute does not match the frequency detected in data"

index(MU) <- year(MU)
attr(MU, 'unit') <- 'mm/day'
## Transform the fields into
fFWMU <- FW*exp(-20/MU)
class(fFWMU) <- class(MU)
## Copy the attributes
fFWMU <- attrcp(MU, fFWMU)
```

```

attr(fFWMU,'variable') <- 'probability'
attr(fFWMU,'unit') <- 'fraction'
print("FW*exp(-20/MU)")

```

```

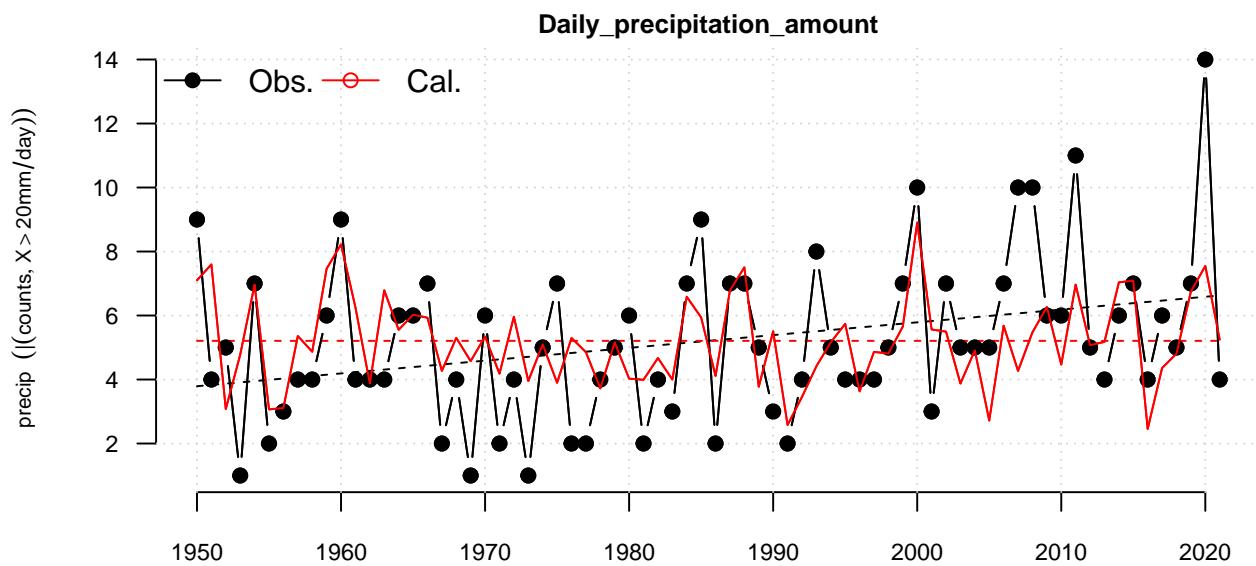

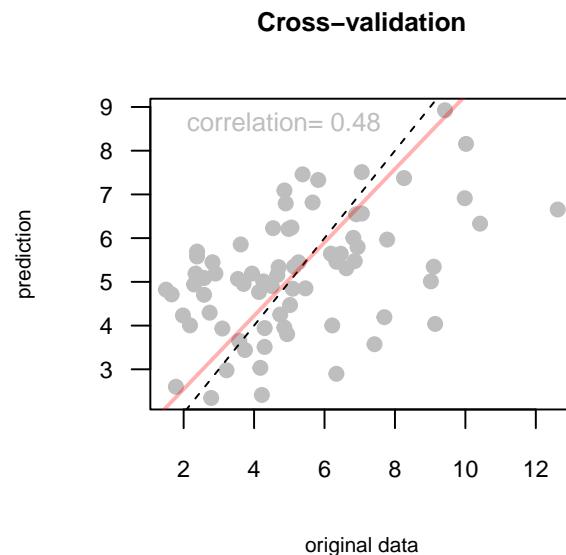

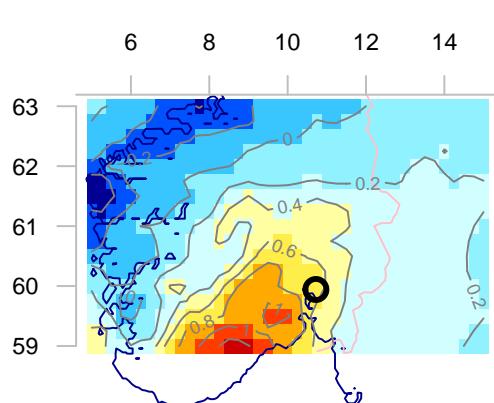

## [1] "FW*exp(-20/MU)"

```

```

eof.fffmu <- EOF(fFWMU)
attr(eof.fffmu,'time') <- range(index(FW))
ds.nvwet1 <- DS(nvwet,eof.fffmu,method = 'glm')
plot(ds.nvwet1,new=FALSE)

```

```

print("FW")

```

```

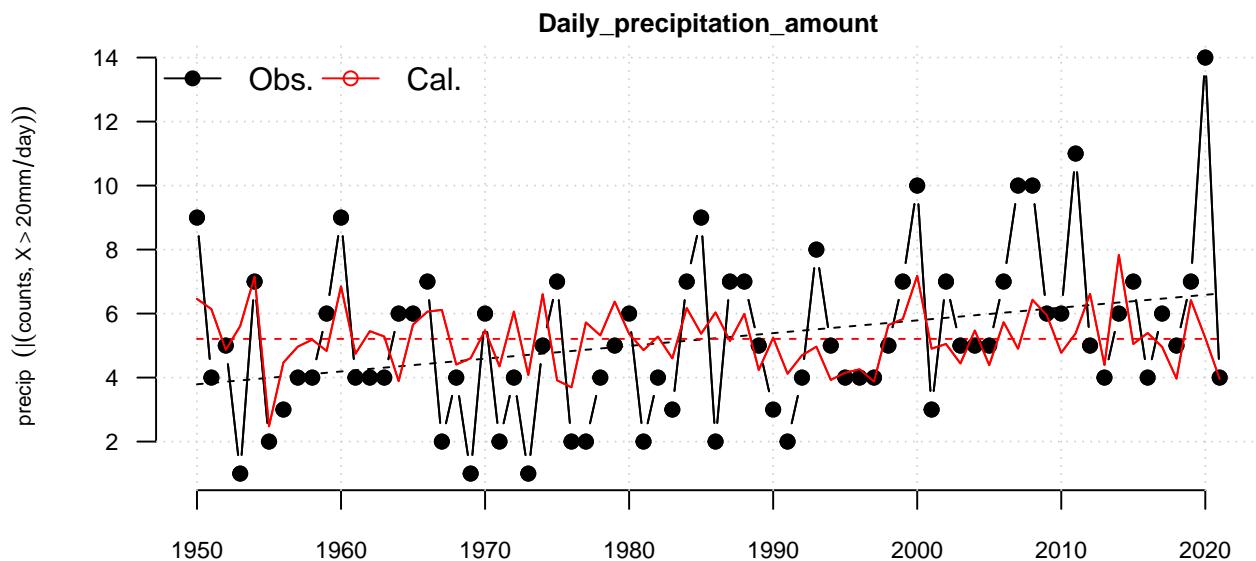

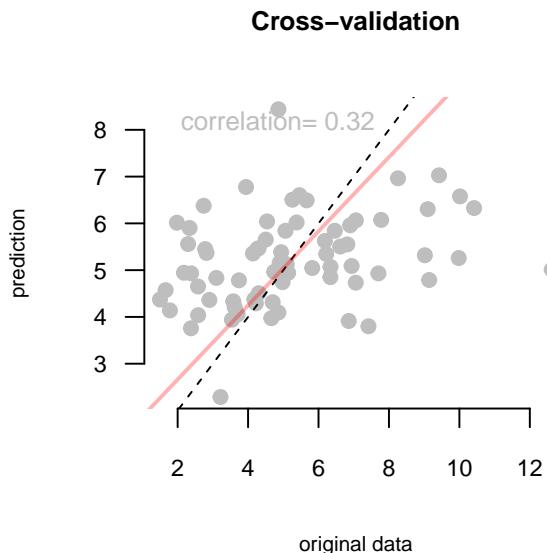

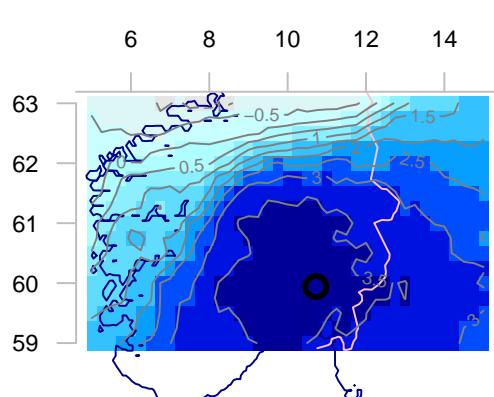

## [1] "FW"

```

```

eof.fw <- EOF(FW)
attr(eof.fw, 'time') <- range(index(FW))
ds.nvwet2 <- DS(nvwet, eof.fw, method = 'glm',)
plot(ds.nvwet2, new=FALSE)

```

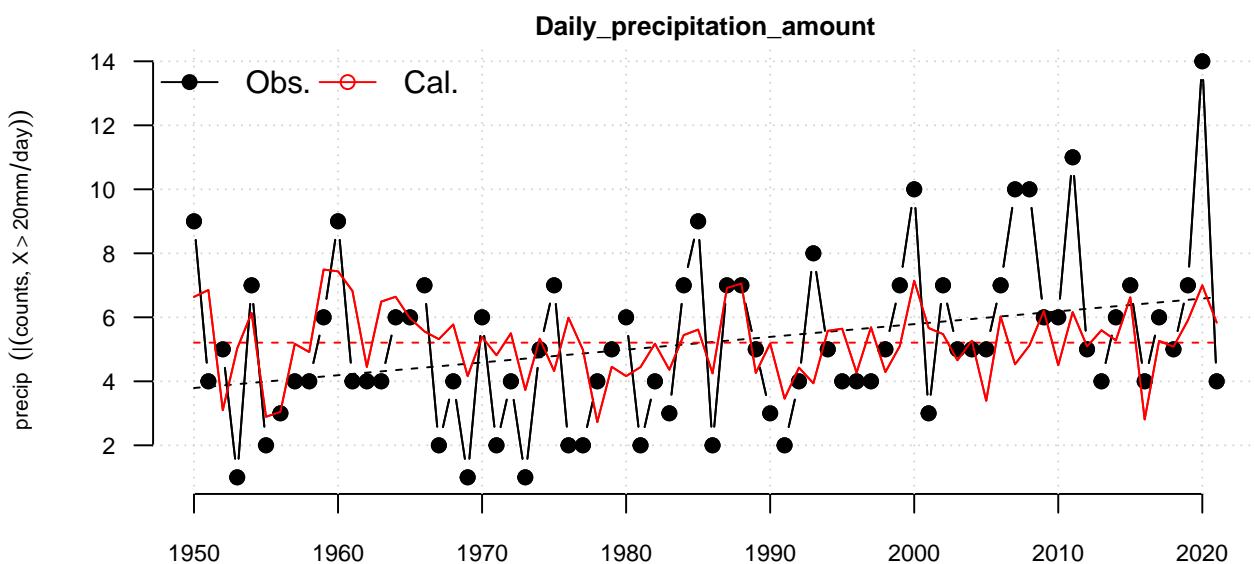

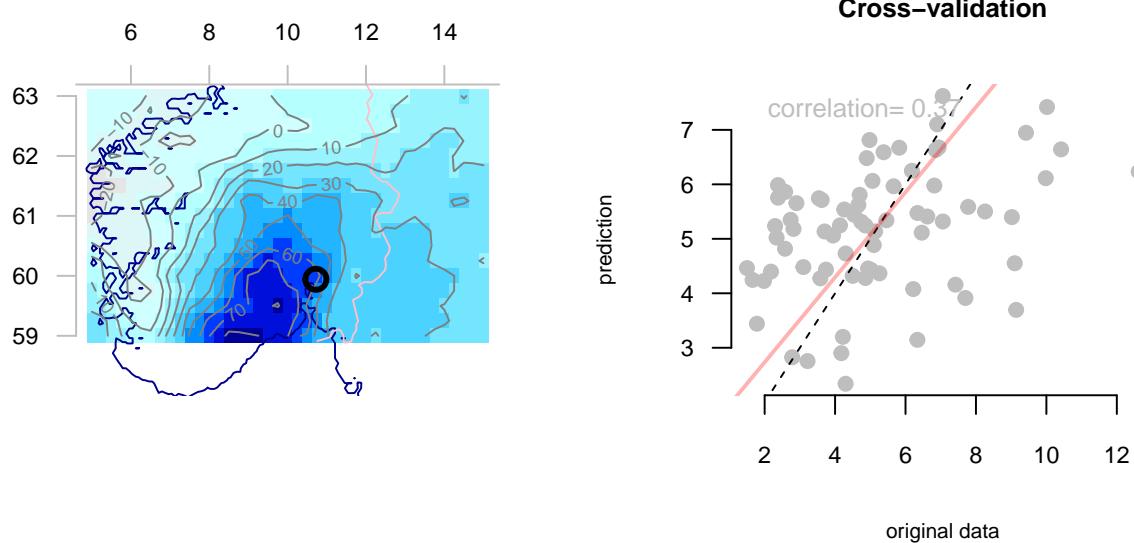

```
print("MU")
```

```
## [1] "MU"
```

```

eof.mu <- EOF(MU)
attr(eof.mu, 'time') <- range(index(FW))
ds.nvwet3 <- DS(nvwet, eof.mu, method = 'glm')
plot(ds.nvwet3, new=FALSE)

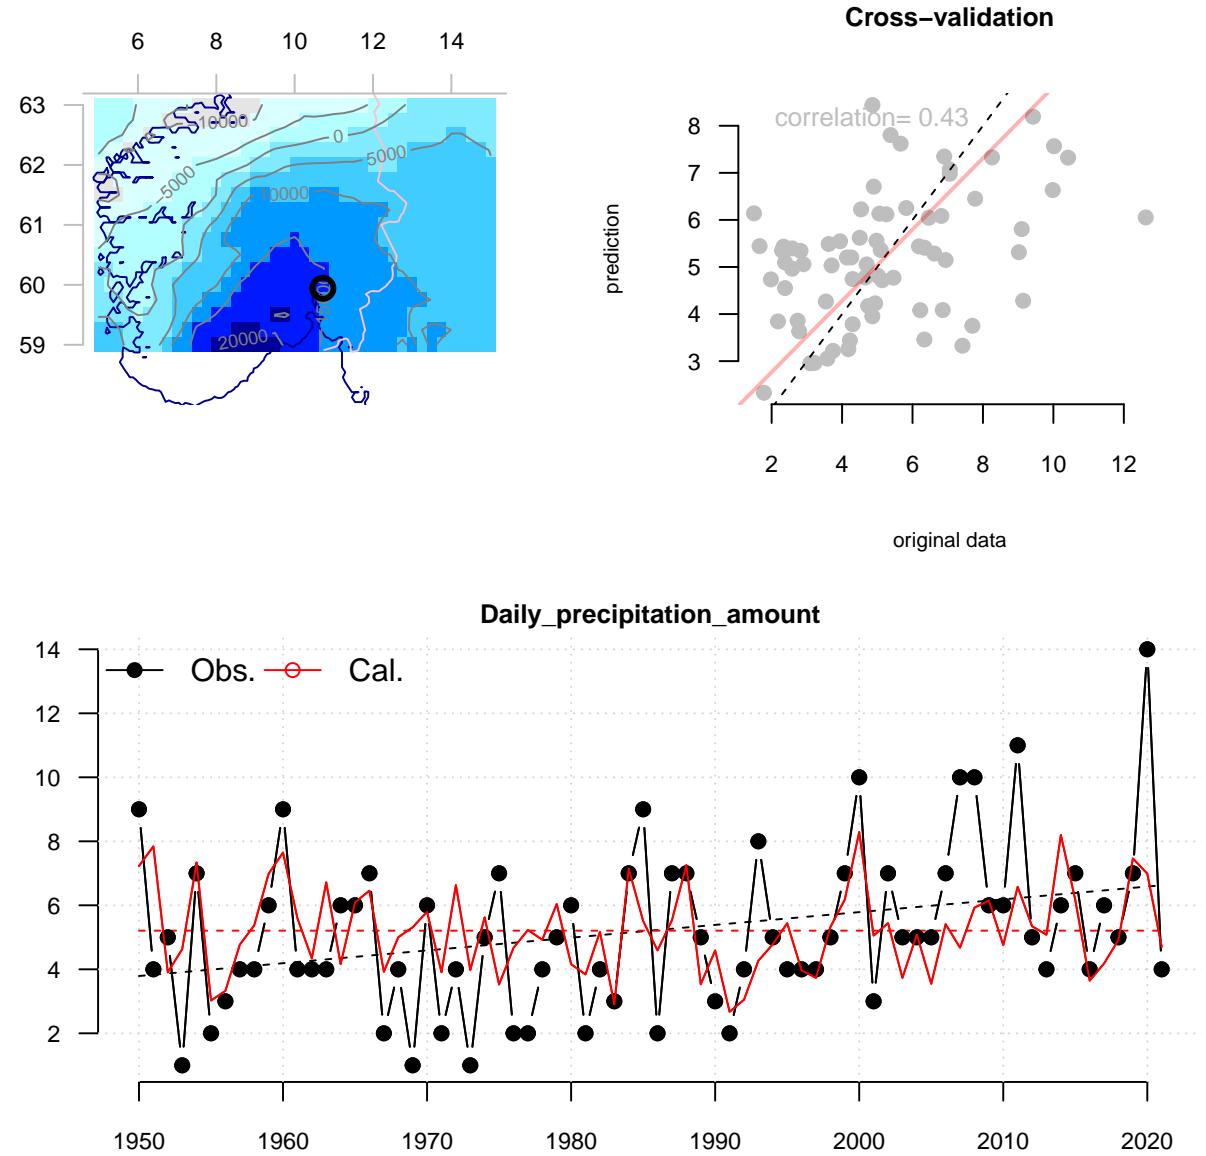

```

```
print("FW*MU")
```

```
## [1] "FW*MU"

PT <- 365.25*FW*MU
class(PT) <- class(FW)
attr(PT, 'variable') <- 'precip'
attr(PT, 'unit') <- 'mm'
PT <- attrcp(FW, PT)
eof.fwmu <- EOF(PT)
attr(eof.fwmu, 'time') <- range(index(FW))
ds.nvwet4 <- DS(nvwet, eof.fwmu, method = 'glm')
plot(ds.nvwet4, new=FALSE)
```

The results from downscaling the number of wet days directly did not capture the observations well in this case. Hence, it seems better to estimate the number/probability of events through downscaling of f_w and μ from their large-scale fields. However, the spatial weights in ERA5 are in the vicinity of Oslo, supporting a connection, albeit imperfect in terms of the magnitude of the number of events.

2.9 Maps and gridded results

The gridded data makes it possible to show maps for the Nordic region. Here `gridmap` involved kriging with altitude as a covariate, based on the R-package `LatticeKrig` <https://cran.r-project.org/web/packages/LatticeKrig/index.html> from UCAR. The default for `dsenseable-objects` in the `esd` package is to show the ensemble mean:

We want to produce maps of change in $Pr(X > x) = f_w \exp(-x/\mu)$ based on the formulation suggested by Benestad et al. (2019): $dPr/dt = \exp(-x/\mu)df_w/dt + f_w x/\mu^2 \exp(-x/\mu)d\mu/dt$. Hence, we require maps for f_w , df_w/dt , μ , and $d\mu/dt$ for each emission scenario.

2.9.1 Wet-day frequency

The following chunk provides maps of mean downscaled f_w and its trend based on the SSP370 emission scenario.

```
## function estimating proportional trend in terms of %
ptrend <- function(x,na.rm=TRUE) {
  mx <- map(x,FUN='mean',plot=FALSE)
  tx <- map(x,FUN='trend',plot=FALSE)
  y <- 100*tx/mx
  class(y) <- class(tx)
  y <- attrcp(tx,y)
  attr(y,'unit') <- '%'
  return(y)
}

## This function extracts the interval where all members of the ensemble are present. It differs from 'allMs' as it works on the PCA-based ensemble results as opposed to single stations.
allMs <- function(x) {
  nt <- length(index(x))

d.fw.ssp585 <- ptrend(esd.results$fw.ssp585)
map(d.fw.ssp585,colbar=list(breaks=seq(-1,1,by=0.1),pal='precip.ipcc'),new=FALSE)
```

The highest annual frequency of rainy days is near the west coast but the trends are close to zero, the proportional changes are typically less than 1% per decade. The projected proportional trends (% with respect to mean f_w) vary between increasing and decreasing f_w over different regions, however, for SSP370 the projections indicate more reductions rather than increases in f_w , especially over southern Scandinavia.

The following chunk provides corresponding maps for μ , also based on downscaled results for the SSP370 emission scenario.

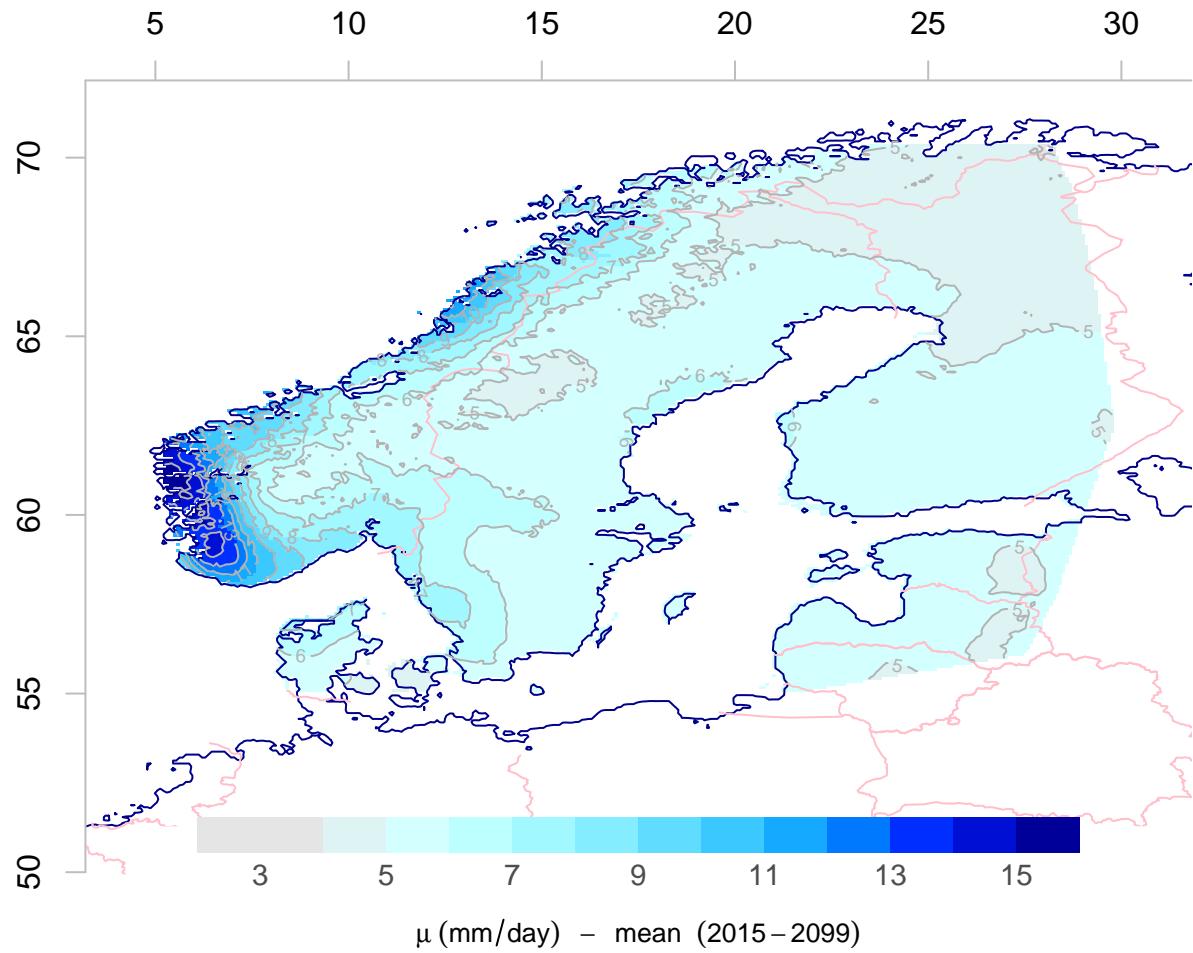

```
esd.results$mu.ssp370 <- allMs(esd.results$mu.ssp370)

## Warning in min(index(x[is.finite(x)])): no non-missing arguments to min;
## returning Inf

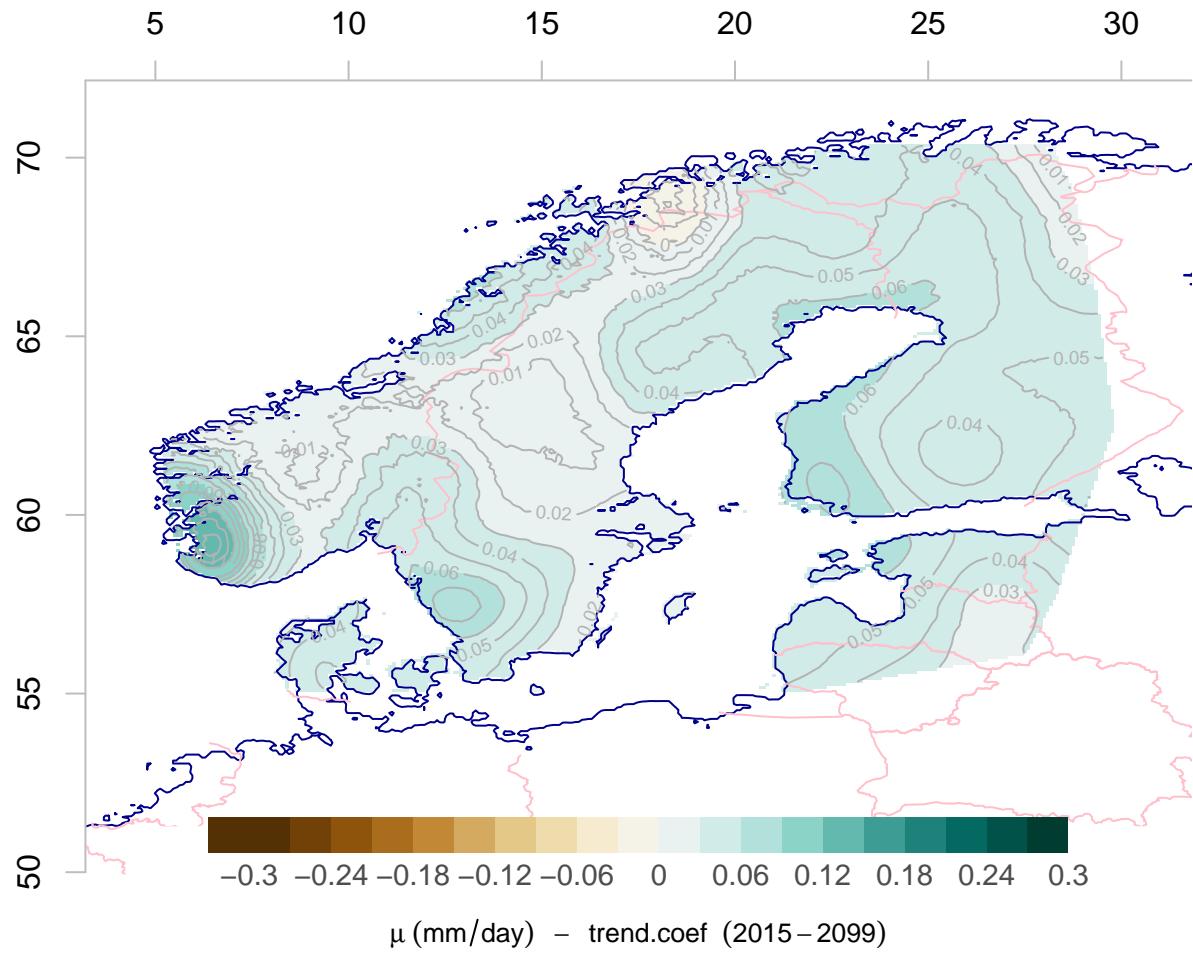

## Warning in max(index(x[is.finite(x)])): no non-missing arguments to max;

```

```
d.mu.ssp245 <- map(esd.results$mu.ssp245,FUN='trend',
                     colbar=list(breaks=seq(-0.3,0.3,by=0.03),pal='precip.ipcc'),new=FALSE)
```

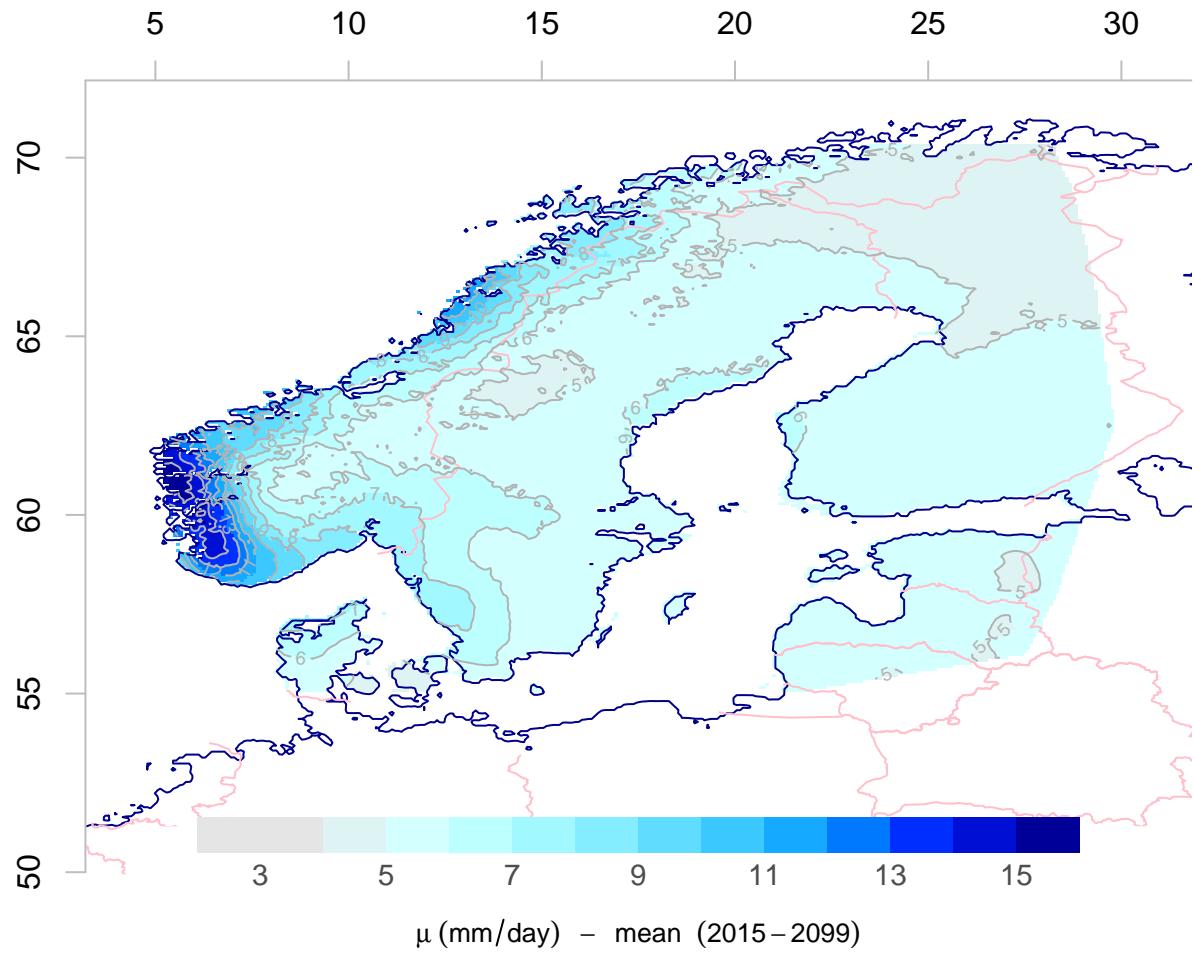

```
esd.results$mu.ssp585 <- allMs(esd.results$mu.ssp585)
```

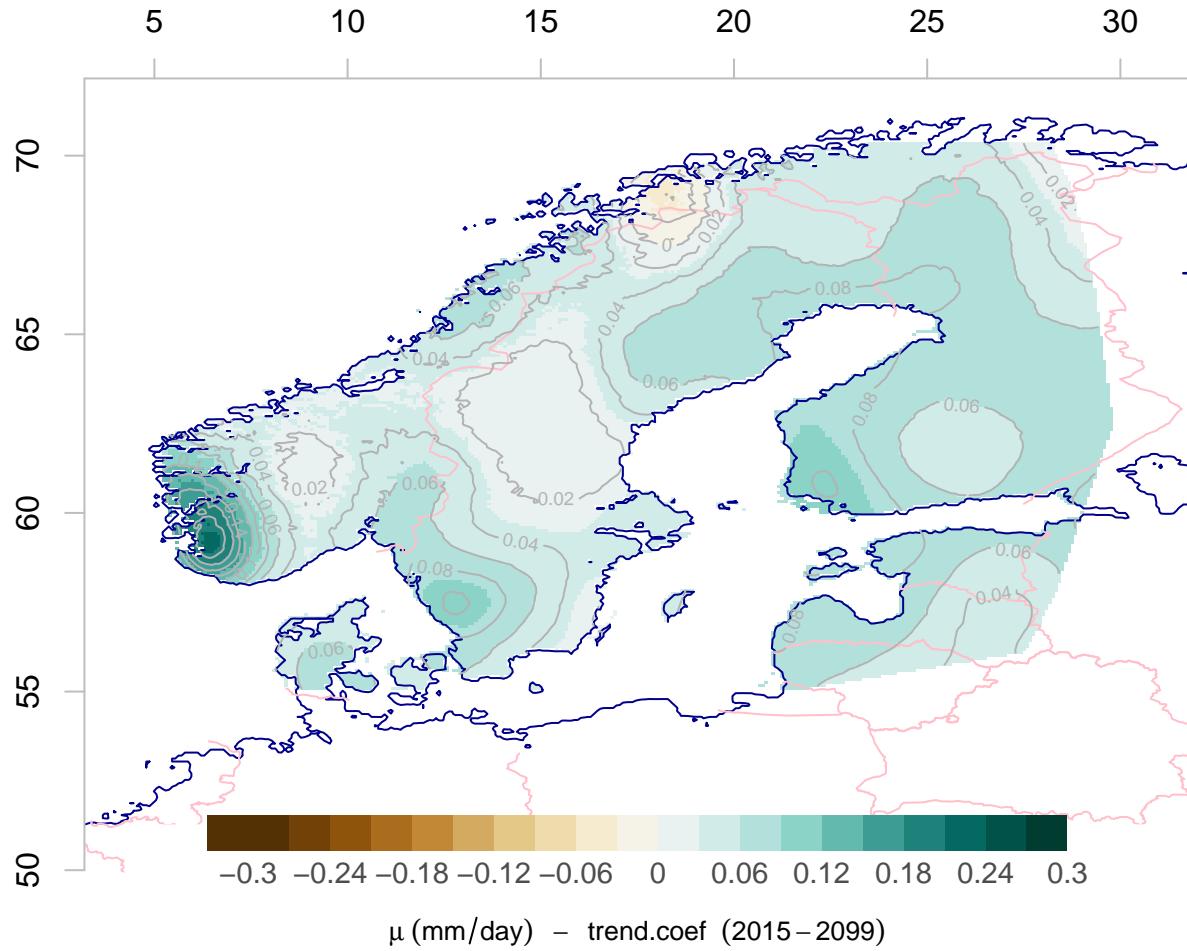

```
## Warning in min(index(x[is.finite(x)])): no non-missing arguments to min;
## returning Inf
## Warning in min(index(x[is.finite(x)])): no non-missing arguments to max;
## returning -Inf
```

```
## [1] 2015 2100
```

```
m.mu.ssp585 <- map(esd.results$mu.ssp585, FUN='mean', new=FALSE)
```

```
d.mu.ssp585 <- map(esd.results$mu.ssp585,FUN='trend',
                     colbar=list(breaks=seq(-0.3,0.3,by=0.03),pal='precip.ipcc'),new=FALSE)
```

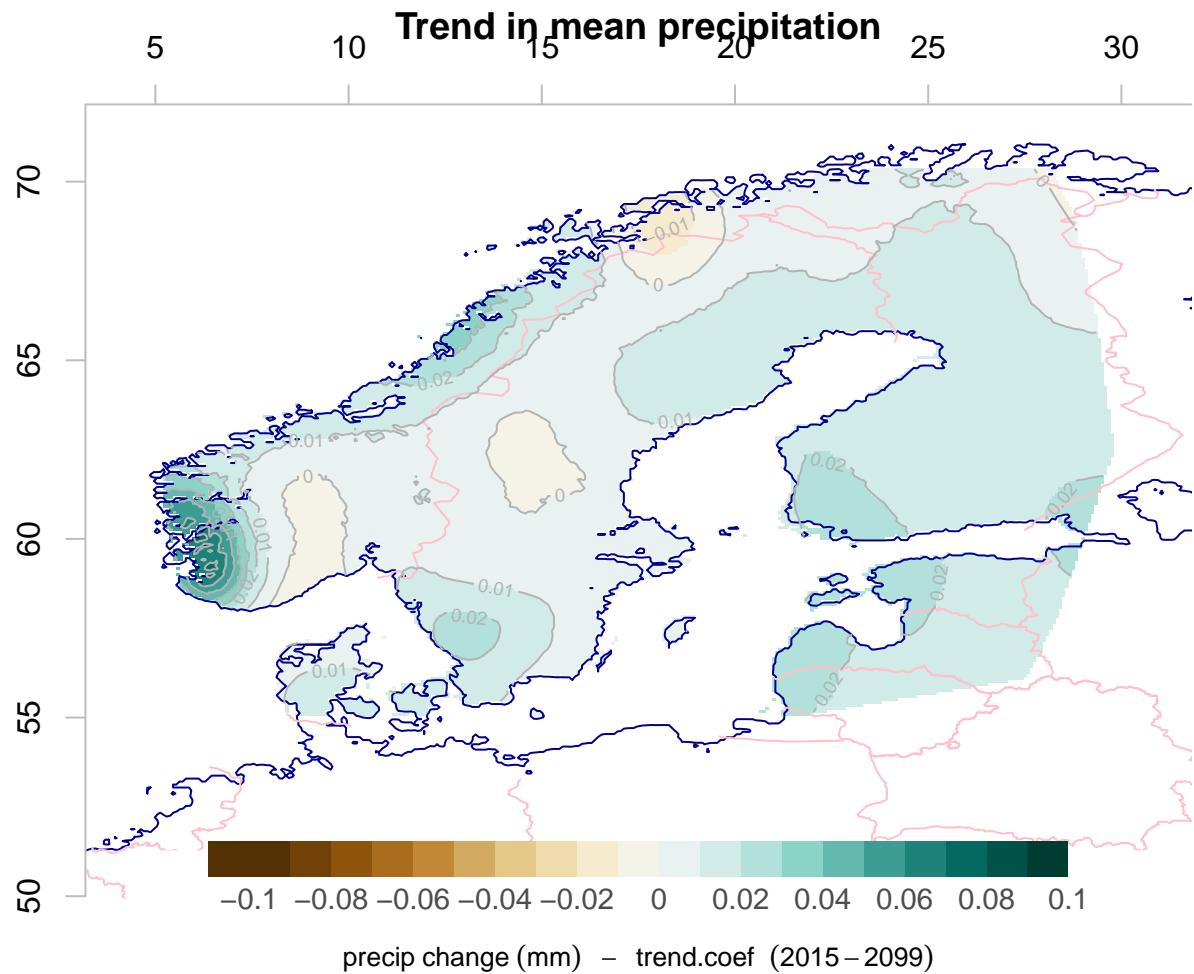

The highest intensity is seen near the west coast of Norway and most of the region is projected to see long-term increases in μ . The projected trends for the future suggest increasing μ for most regions, but there are also some exceptions.

2.9.2 Changes in total precipitation

It is useful to analyse trends in the mean precipitation $\bar{x} = f_w\mu$, as $\delta\bar{X} = \mu\delta f_w + f_w\delta\mu$.

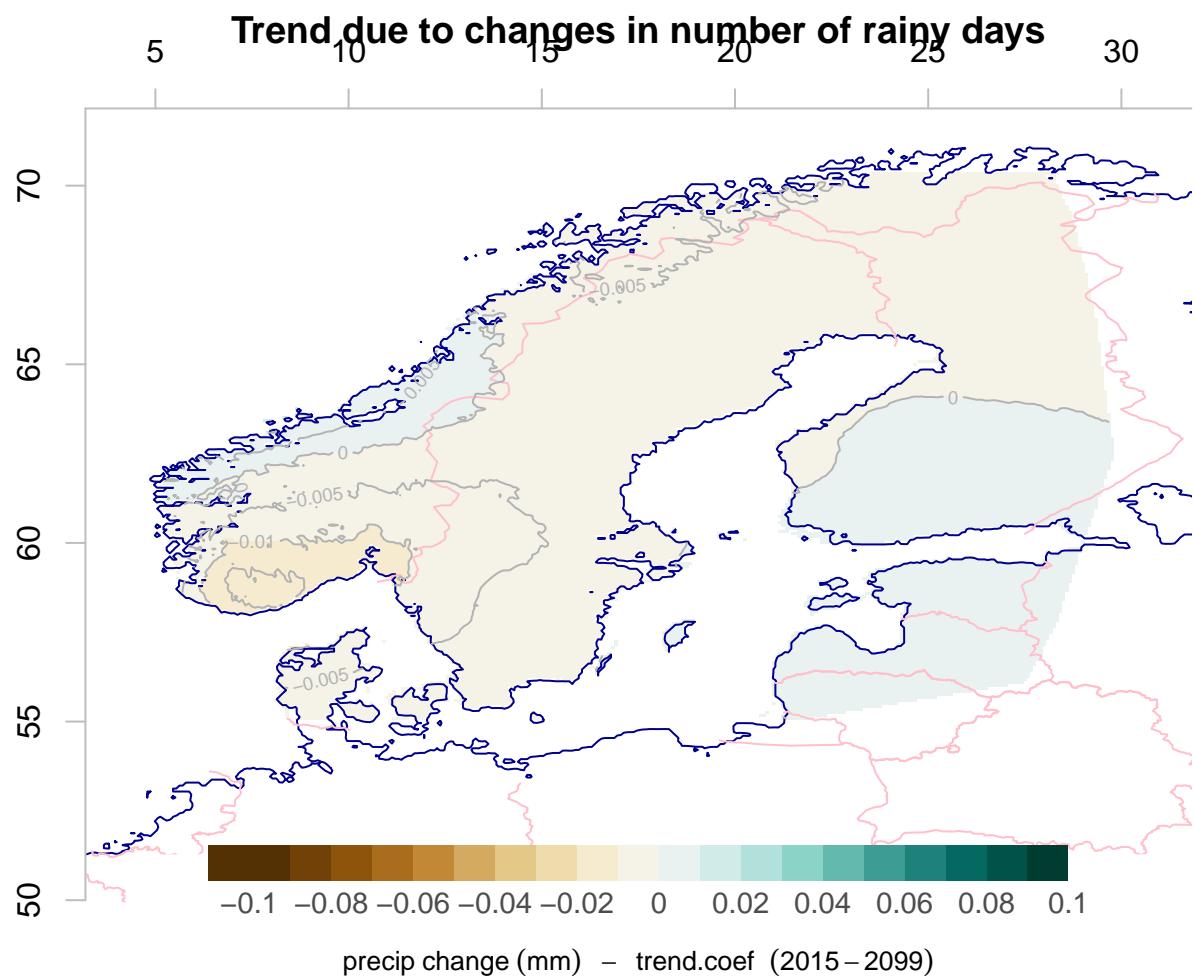

```
## Use the trend in fraction as opposed to the proportional trend in the following
## calculations
d.fw.ssp370 <- map(esd.results$fw.ssp370,FUN='trend',plot=FALSE)
dp1 <- d.fw.ssp370*m.mu.ssp370
attr(dp1,'variable') <- 'precip change'
attr(dp1,'unit') <- 'mm'
dp2 <- m.fw.ssp370*d.mu.ssp370
## Trend in rainfall:
map(dp1+dp2,colbar=list(breaks=seq(-0.1,0.1,by=0.01),pal='precip.ipcc'),
 main='Trend in mean precipitation')
```

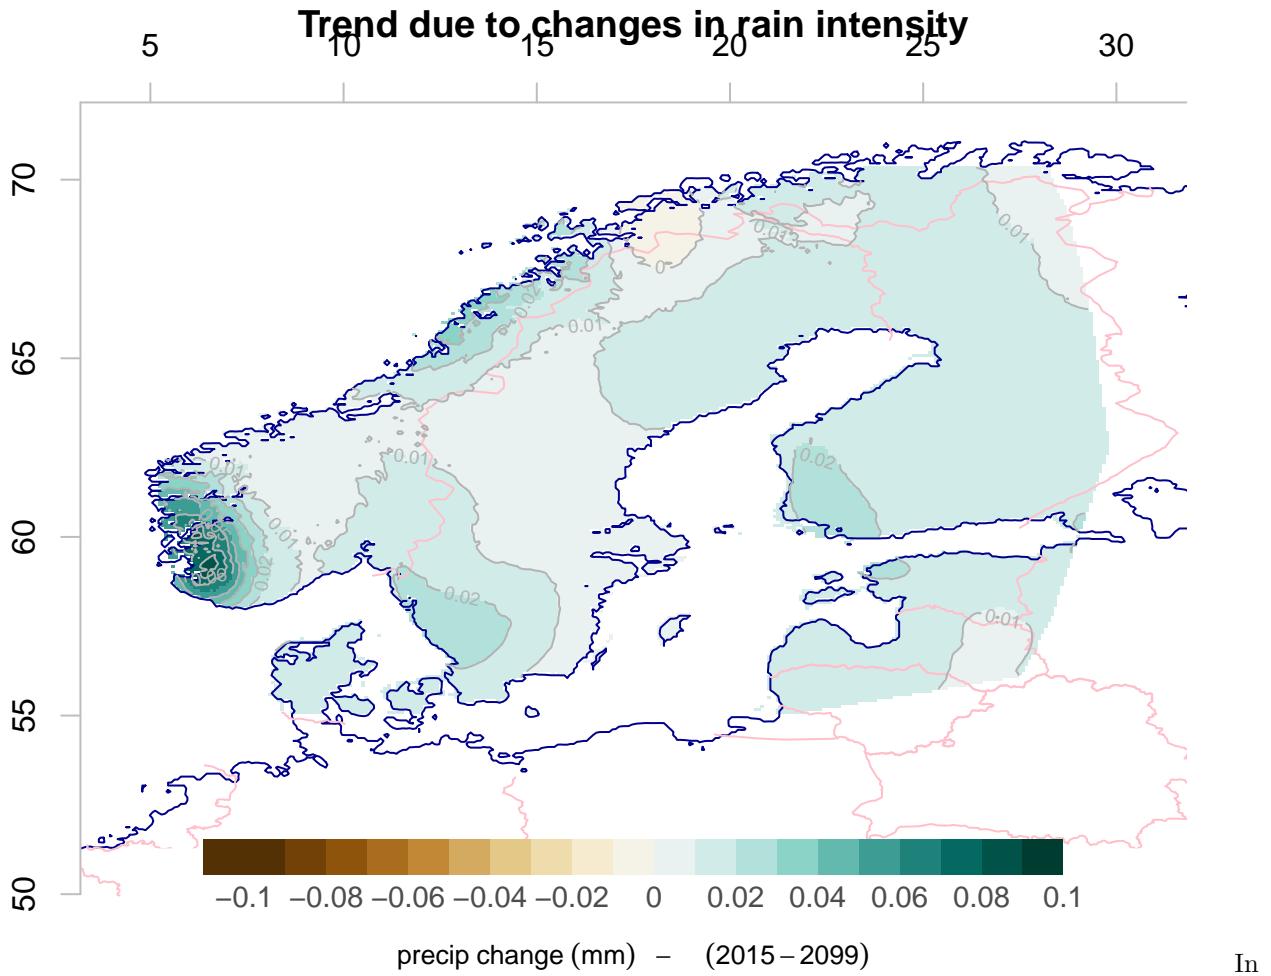

```

attr(dp2,'variable') <- 'precip change'
attr(dp2,'unit') <- 'mm'
map(dp1,colbar=list(breaks=seq(-0.1,0.1,by=0.01),pal='precip.ipcc'),
    main='Trend due to changes in number of rainy days')

```

```
map(dp2,colbar=list(breaks=seq(-0.1,0.1,by=0.01),pal='precip.ipcc'),
    main='Trend due to changes in rain intensity')
```

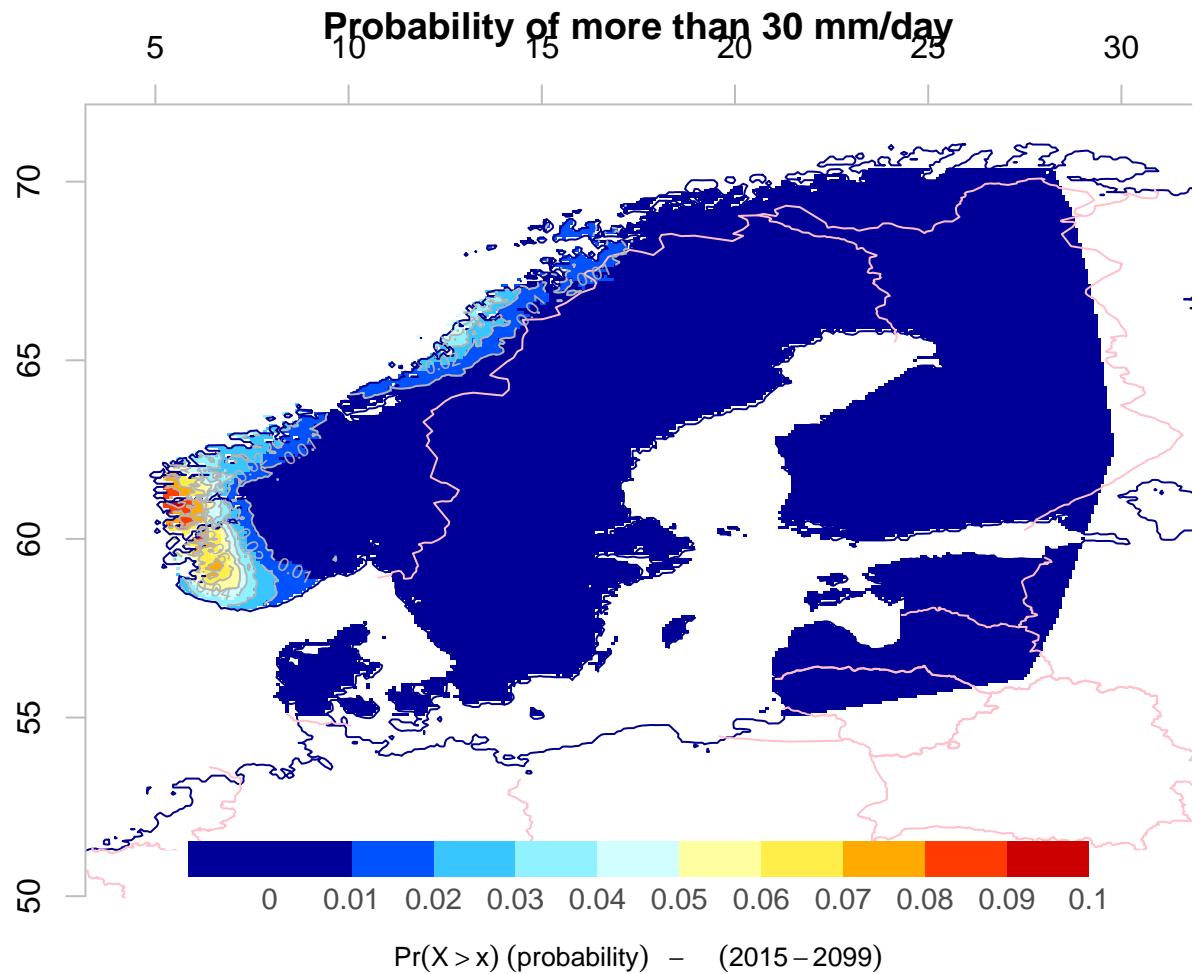

some regions, the contributions to the trend in the mean (total) precipitation amounts are highest from changing number of rainy days (dark blue shades), but there are also regions where increased intensity play a bigger role (red regions). This may be a result of a general lack of trend in f_w and where random fluctuations connected to internal variability swings around zero.

2.9.3 Changes in $Pr(X > x)$

The maps of f_w and μ can also be used to calculate changes in the probability of heavy daily rainfall. We can estimate the contributions to changing probabilities for heavy rainfall from our parameterised equation $Pr(X > x) = f_w \exp(-x/\mu)$ through the product rule for differentiation: $dPr(X > x)/dt = df_w/dt \exp(-x/\mu) + f_w x / \mu^2 \exp(-x/\mu) d\mu/dt$:

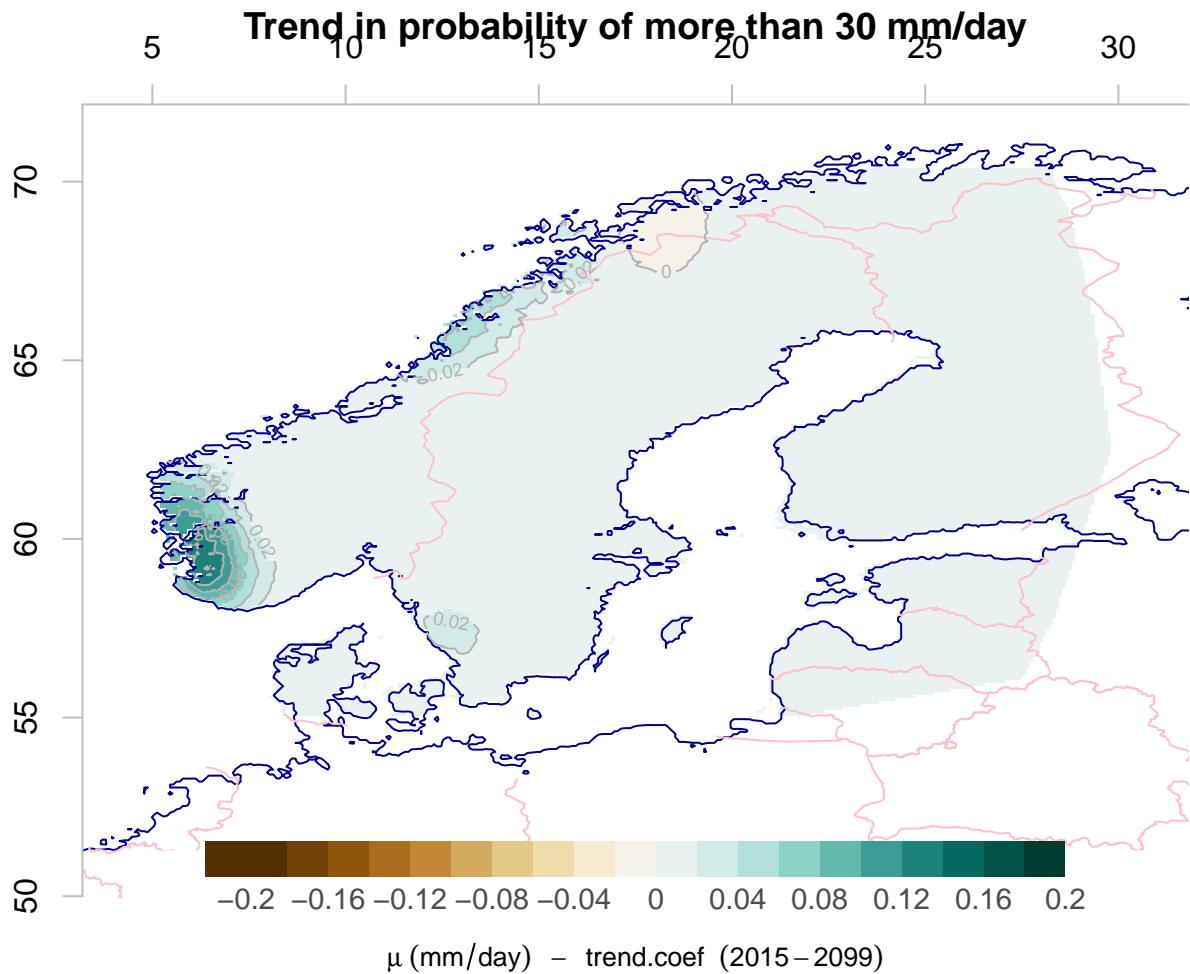

```
x <- 30
exp.x <- exp(-x/m.mu.ssp370)
Pr.gt.x <- m.fw.ssp370*exp.x
attr(Pr.gt.x, 'variable') <- 'Pr(X>x)'
attr(Pr.gt.x, 'unit') <- 'probability'
map(Pr.gt.x, main='Probability of more than 30 mm/day')
```

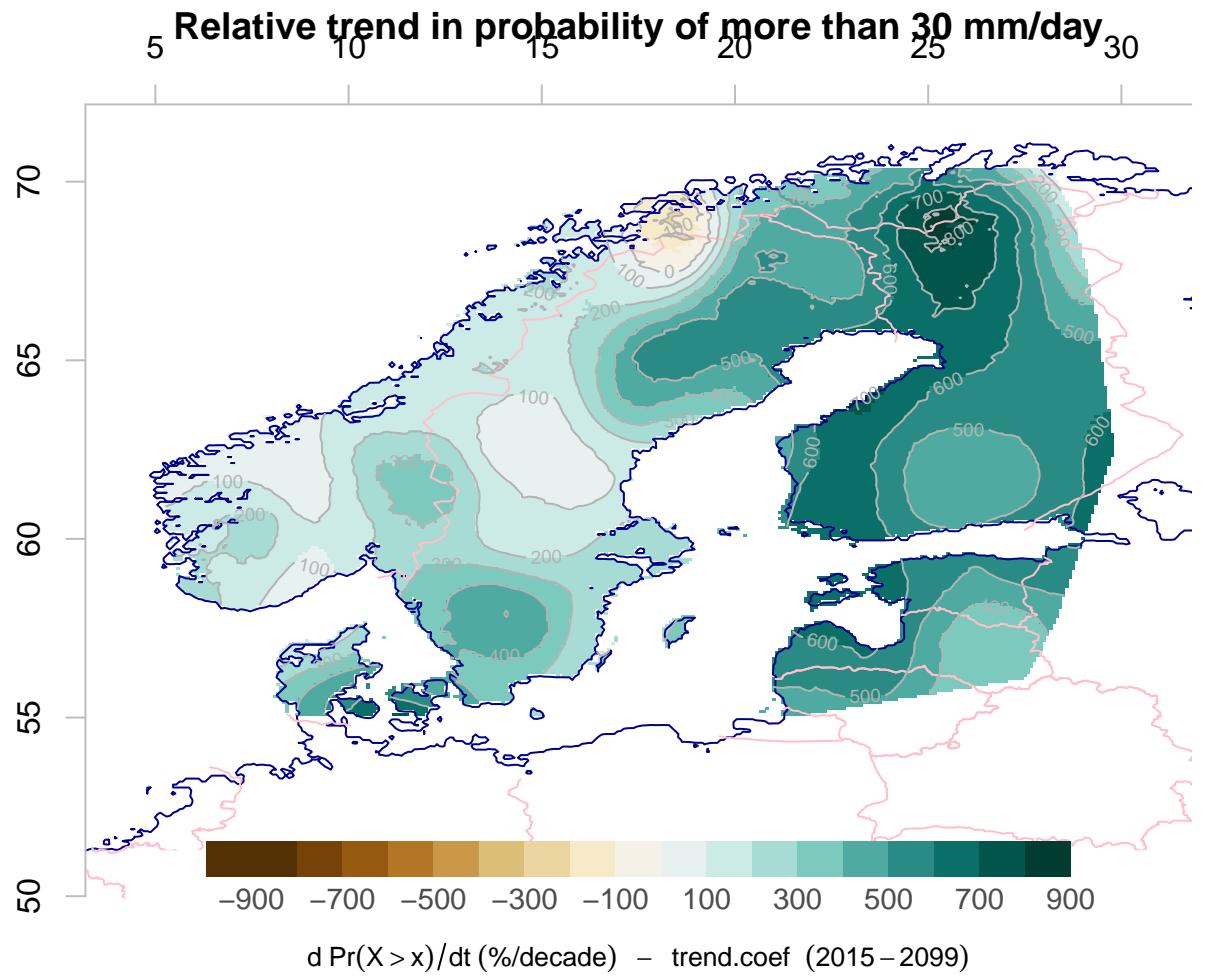

```

dPr.dfw <- exp.x*d.fw.ssp370
dPr.dmu <- x*m.fw.ssp370*exp.x/m.mu.ssp370^2 * d.mu.ssp370
## Trend in probability of daily precipitation exceeding 30 mm/day
dPr.gt.30.ssp370 <- 100*(dPr.dfw + dPr.dmu)
map(dPr.gt.30.ssp370,colbar=list(breaks=seq(-0.2,0.2,by=0.02),pal='precip.ipcc'),
    main='Trend in probability of more than 30 mm/day')

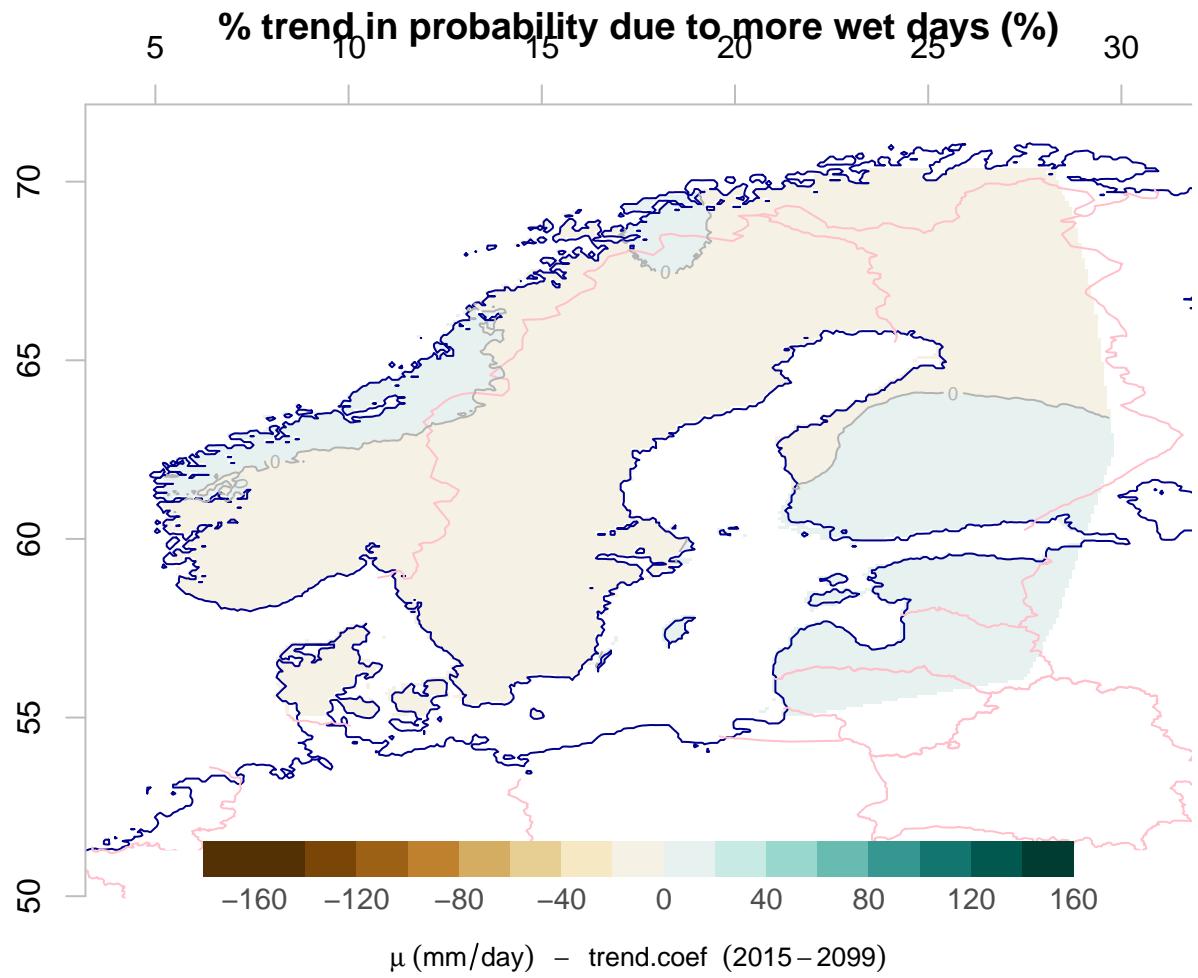

```

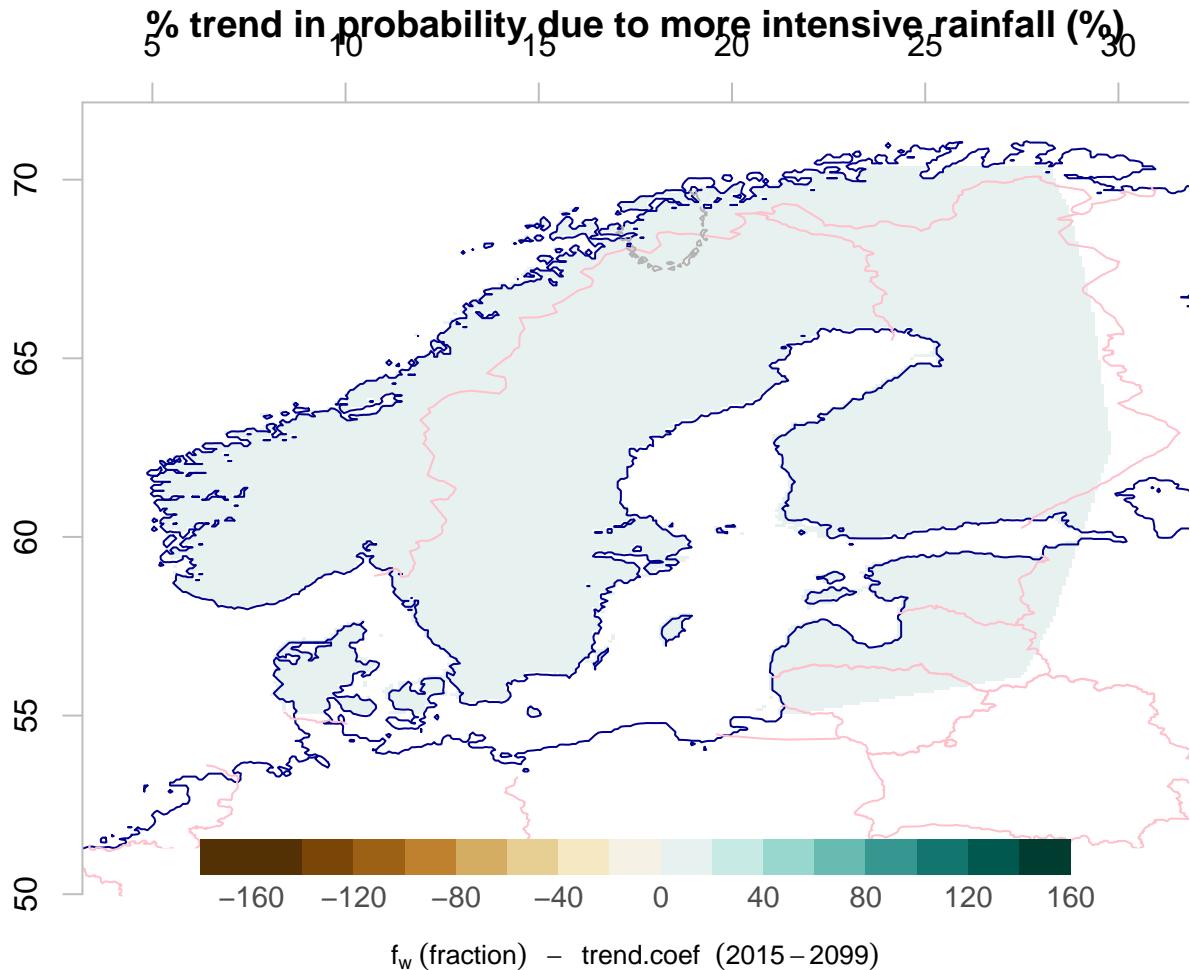

```
## Relative change:
ptPr <- 100*dPr.gt.30.ssp370/Pr.gt.x
attr(ptPr,'variable') <- 'd Pr(X>x)/dt'
attr(ptPr,'unit') <- '%" /decade" '
map(ptPr,colbar=list(breaks=seq(-900,900,by=100),pal='precip.ipcc'),
    main='Relative trend in probability of more than 30 mm/day')
```

```
## Attribution of change to changing number of days or changing
map(100*dPr.dfw/dPr.gt.30.ssp370,colbar=list(breaks=seq(-160,160,by=20),pal='precip.ipcc'),
    main='% trend in probability due to more wet days (%)')
```

```
map(100*dPr.dmu/dPr.gt.30.ssp370,colbar=list(breaks=seq(-160,160,by=20),pal='precip.ipcc'),
  main='% trend in probability due to more intensive rainfall (%)')
```

The increase in μ implies an increase in the probability of days with more than 30 mm/day by 0-20% relative to the original probability. The strongest trend was found in northern Finland.

2.10 Return values

Return values refer to the typical maximum amount of precipitation that can be expected over a time interval of τ years.

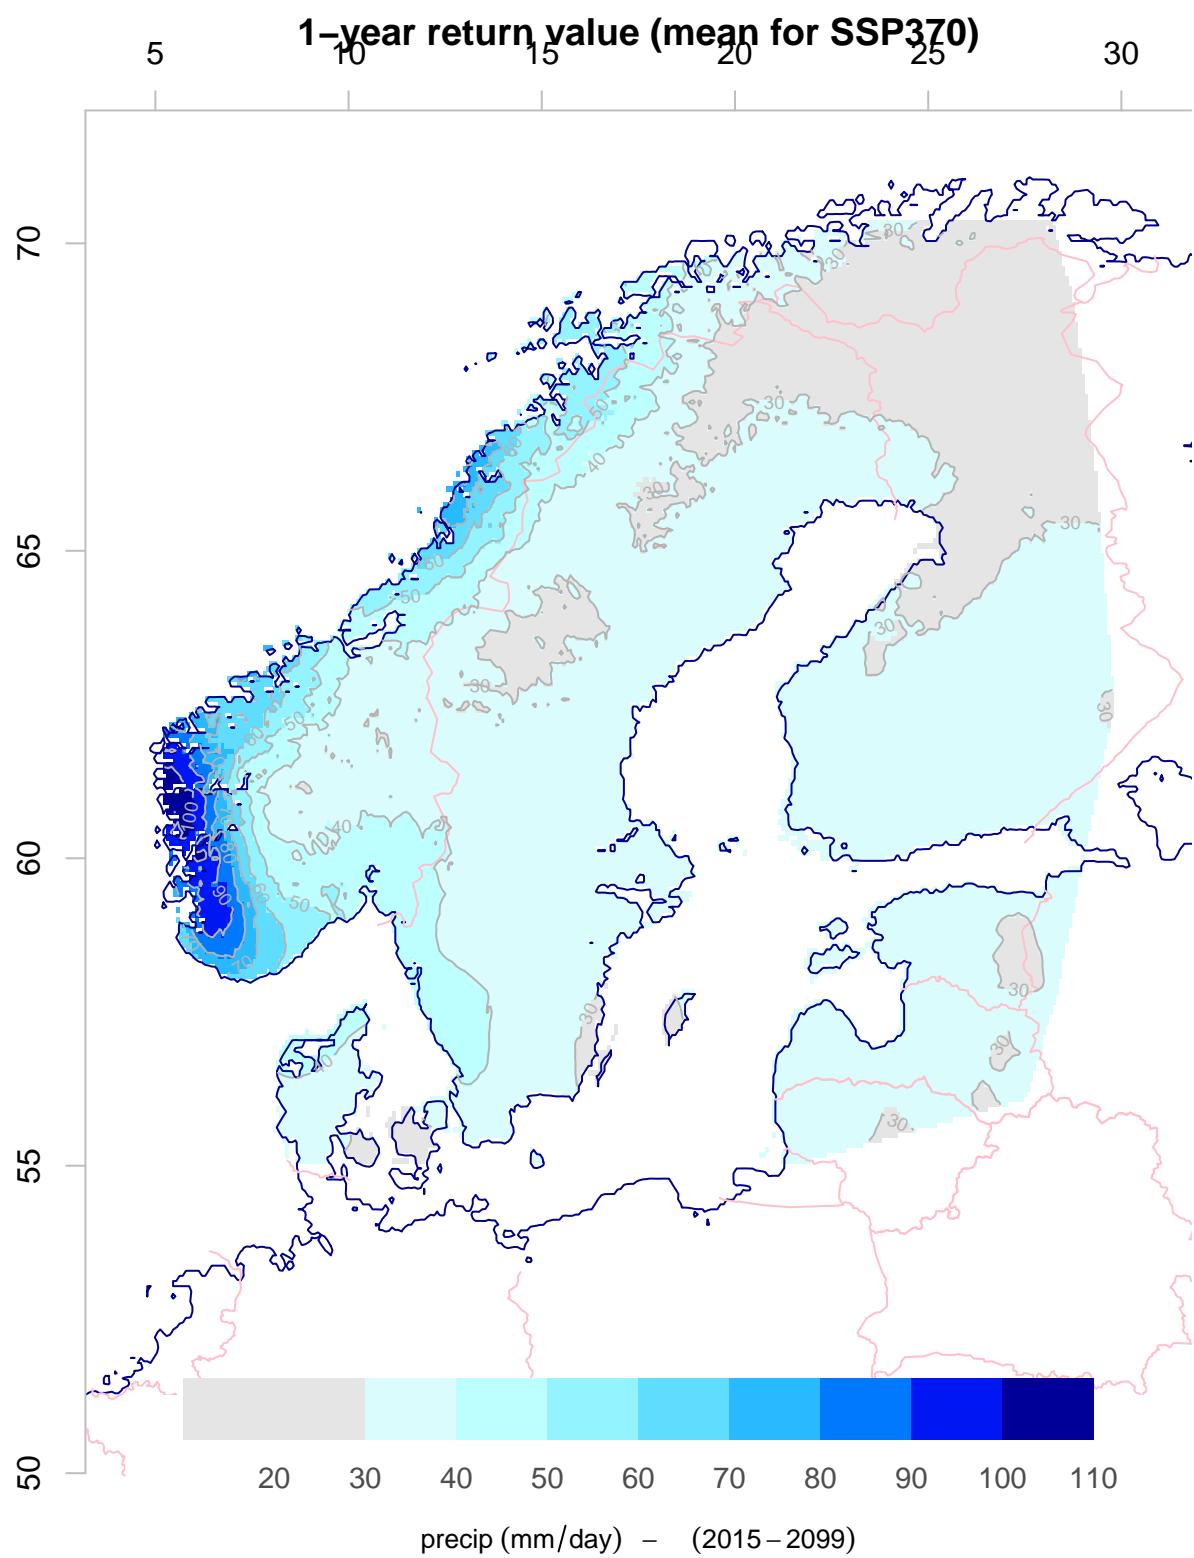

Here, 1-year, 10-year and 25-year return values were calculated using the approximate expression $x_\tau = \alpha\mu \ln(f_w \tau)$, based on derivations in Benestad et al. (2019). The corresponding rate of change (trend) was calculated based on $x_\tau = \alpha \ln(f_w \tau) \delta\mu + \alpha\mu \ln(f_w \tau)$, taking $d/dt \ln(f_w \tau) = d \ln(u)/du * du/dt = 1/udu/dt = 1/f_w * df_w/dt$.

```
## The coefficient alpha is log-linear
c.alpha = c(1.256, 0.064)
layout(matrix(1,1,1))
## tau is the return-interval in number of years
for (tau in c(1, 10, 25)) {
  ## Estimate the value for alpha for given return-interval
  alpha <- c.alpha[1] + c.alpha[2] * log(tau)
  ## Estimate the mean return-value based on the above expression:
  x.L <- alpha * m.mu.ssp370 * log(m.fw.ssp370 * tau * 365.25)
  attr(x.L,'variable') <- 'precip'
```

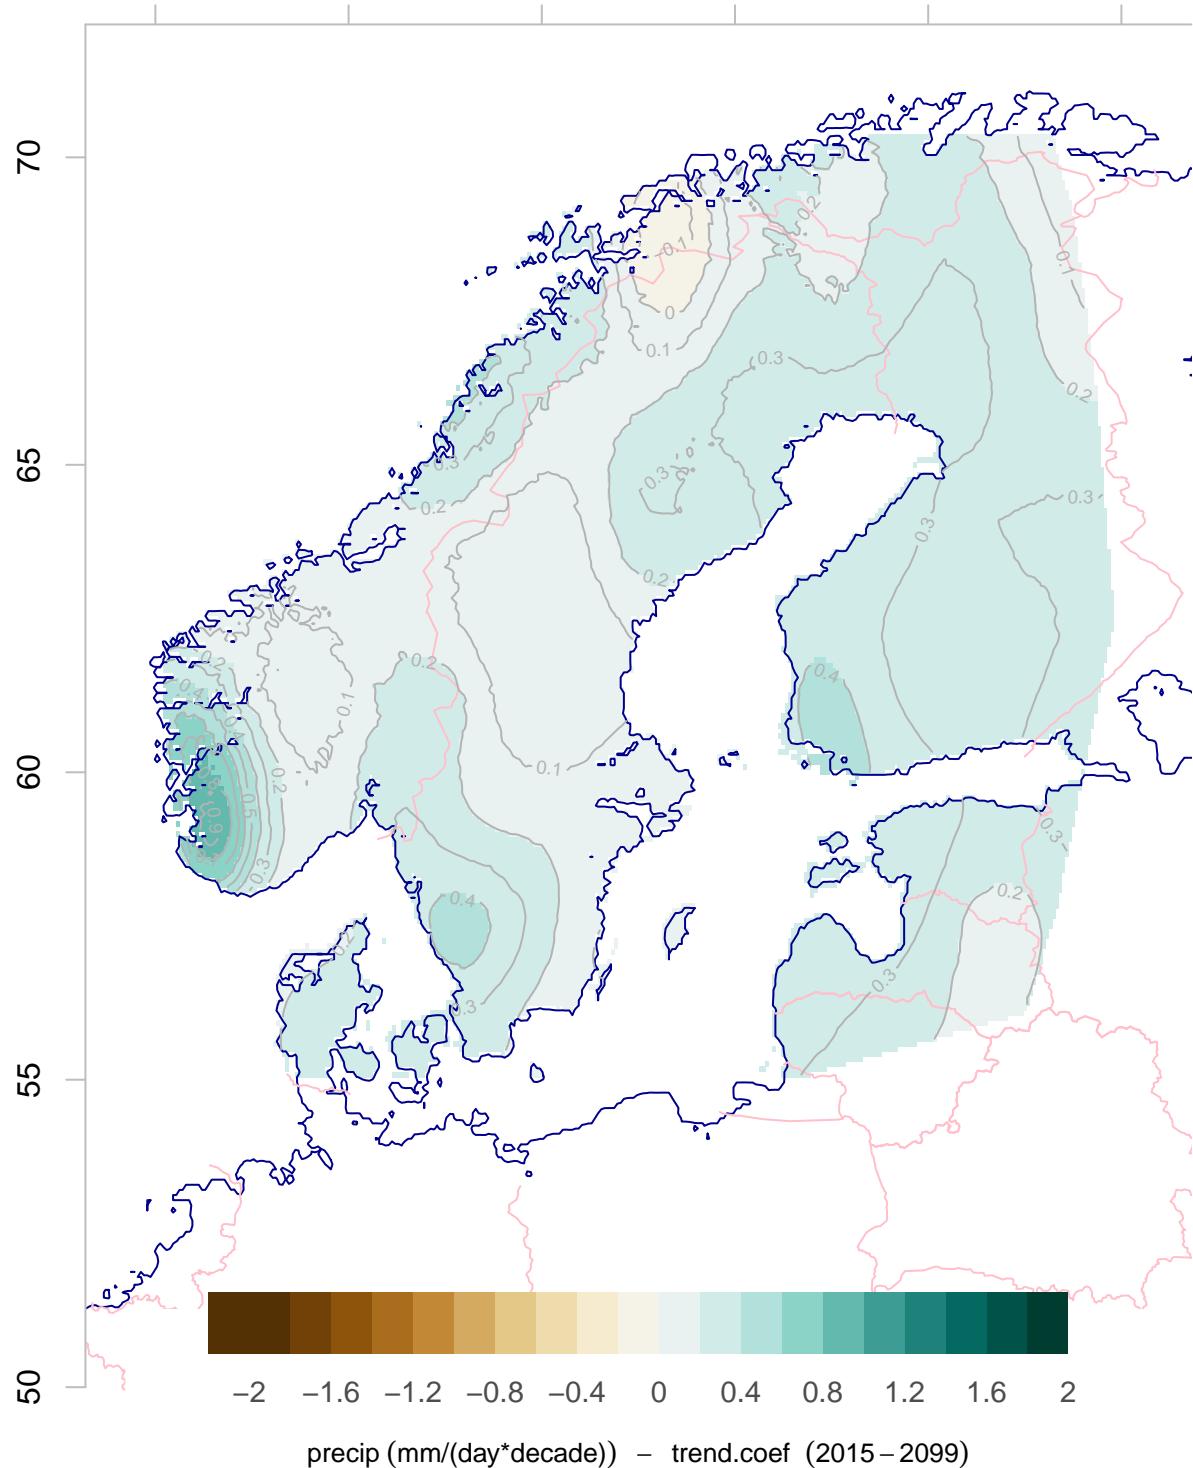

```

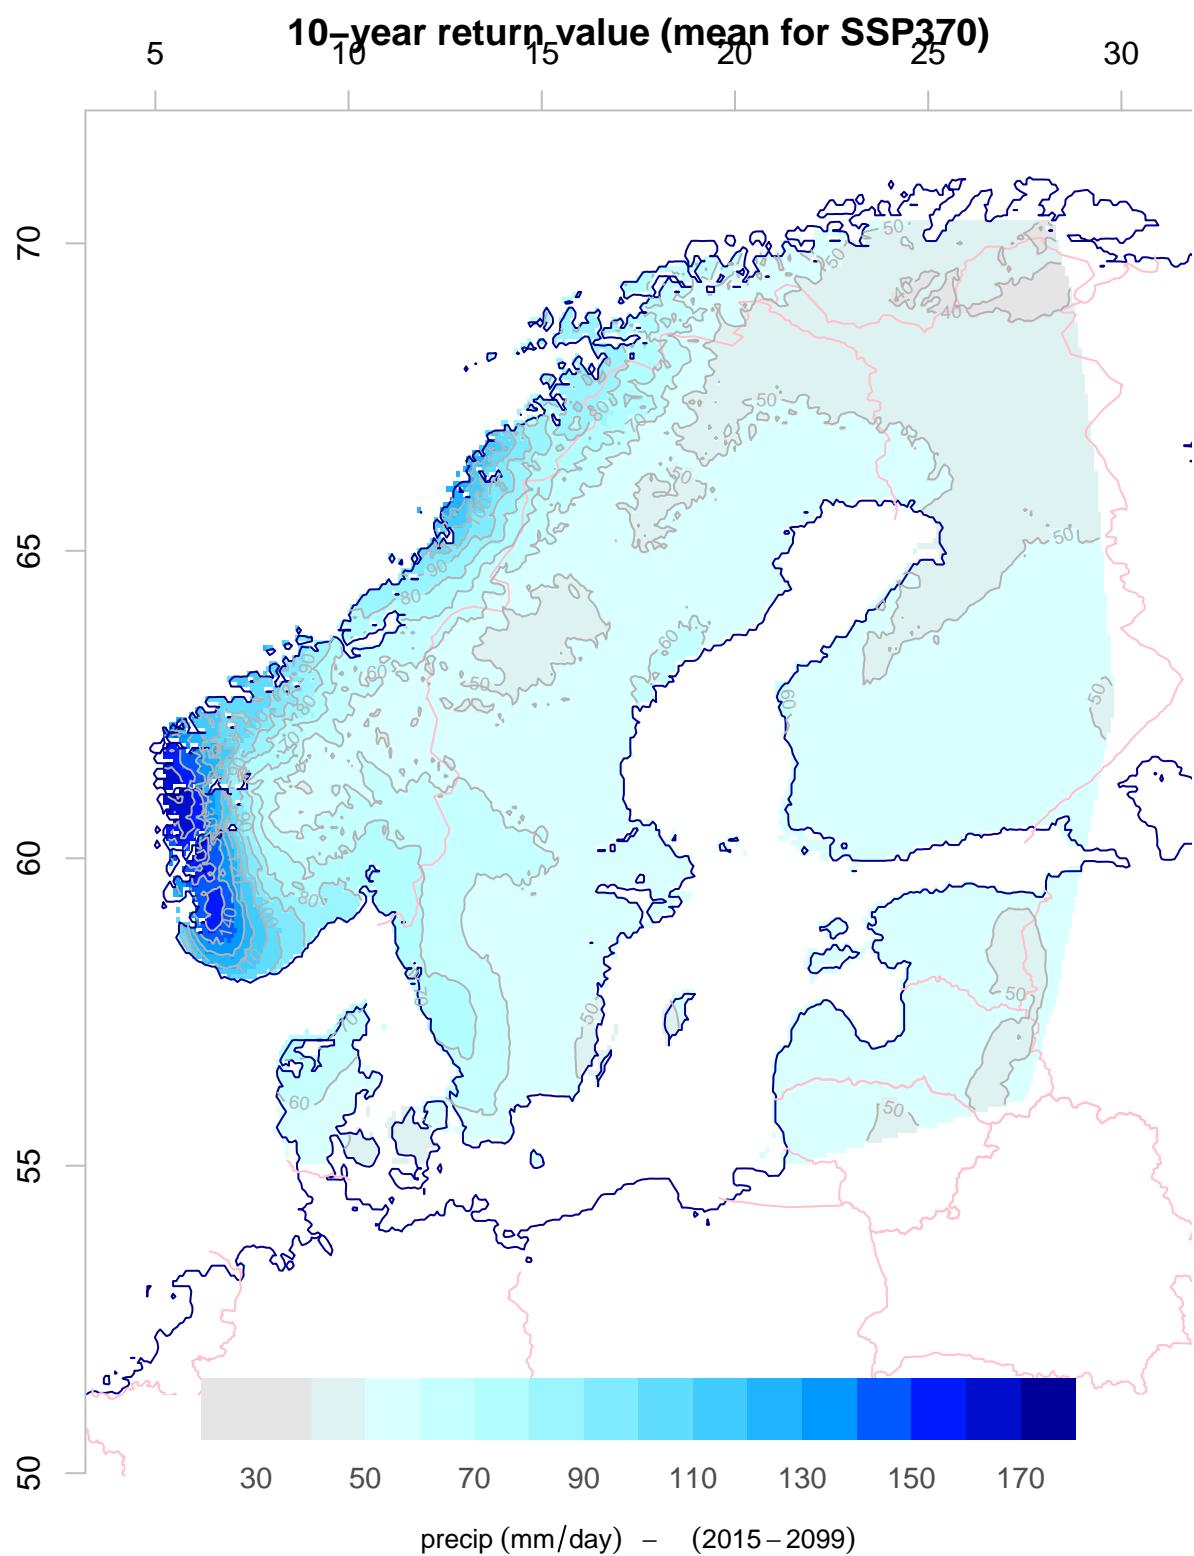

attr(x.L,'unit') <- 'mm/day'
map(x.L,main=paste0(tau,'-year return value (mean for SSP370)'),new=FALSE)
## Estimate change
d.x.L <- alpha * d.mu.ssp370 * log(m.fw.ssp370 * tau * 365.25) +
  alpha * m.mu.ssp370 * d.fw.ssp370/m.fw.ssp370
attr(d.x.L,'variable') <- 'precip'
attr(d.x.L,'unit') <- '"mm/(day*decade)"'
## The Knitting doesn't get these figures quite right
par(new=FALSE,mfcol=c(1,1))
map(d.x.L,colbar=list(breaks=seq(-2,2,by=0.2),pal='precip.ipcc'),
  main=paste0('Trend in the ',tau,'-year return value (mean for SSP370)'),new=FALSE)
}

```

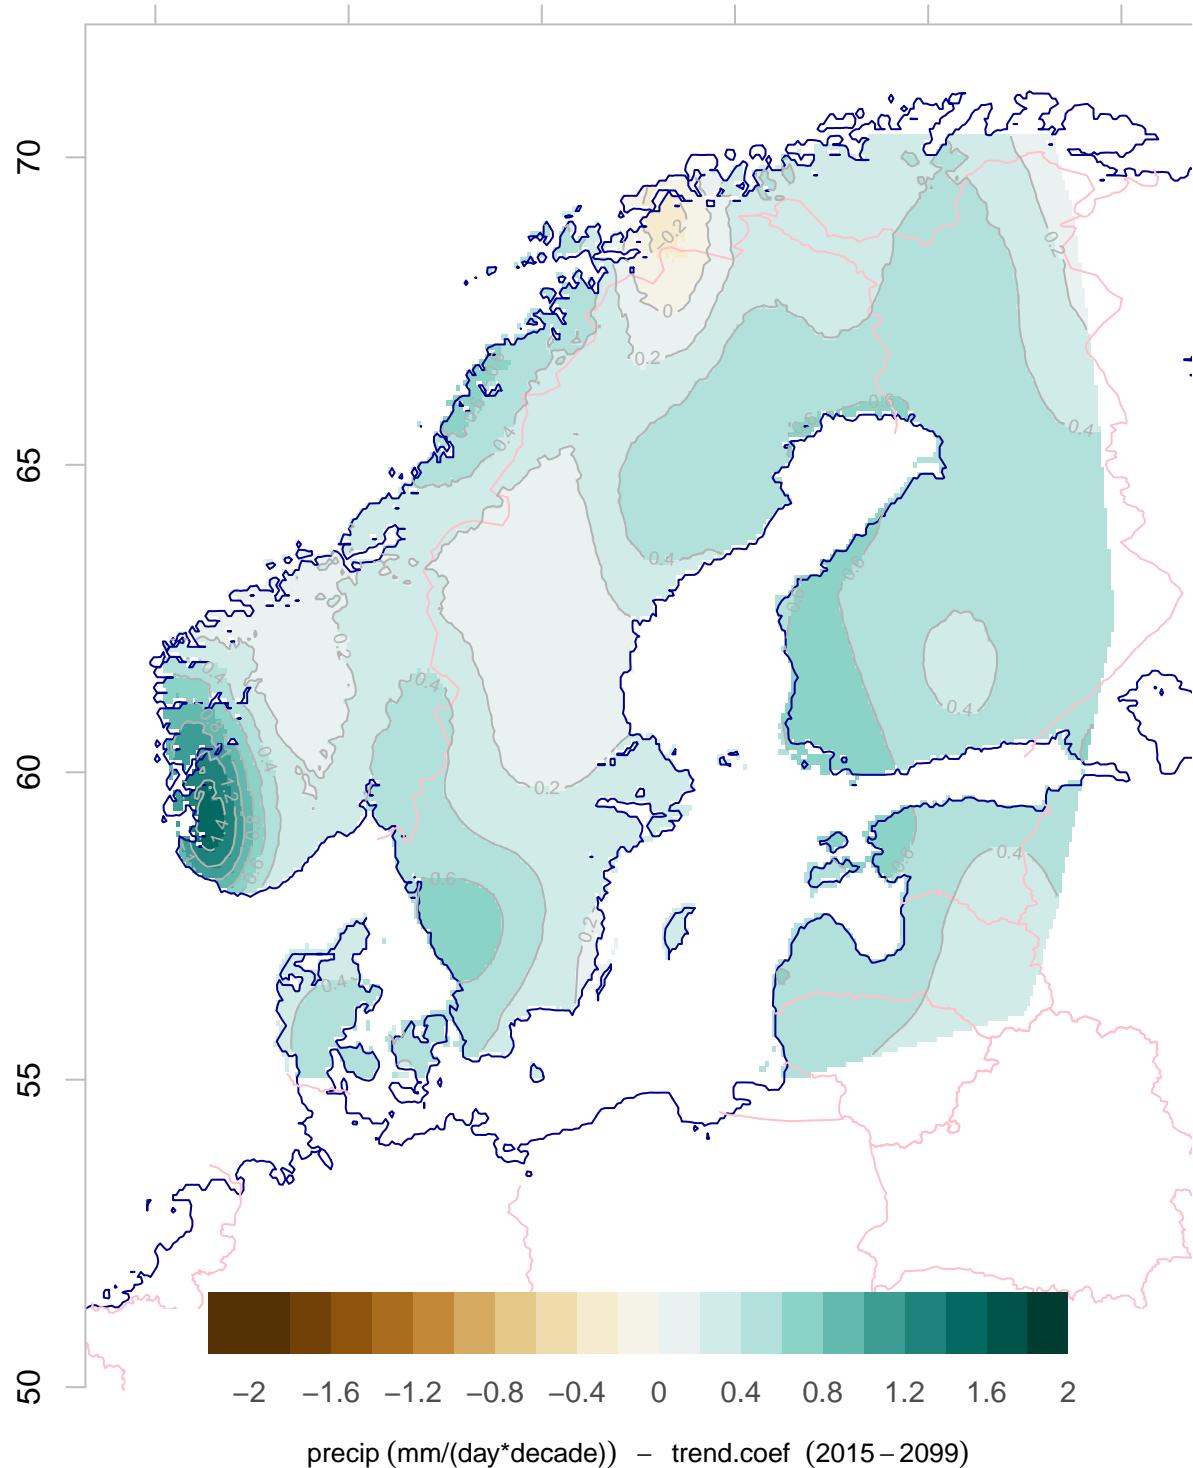

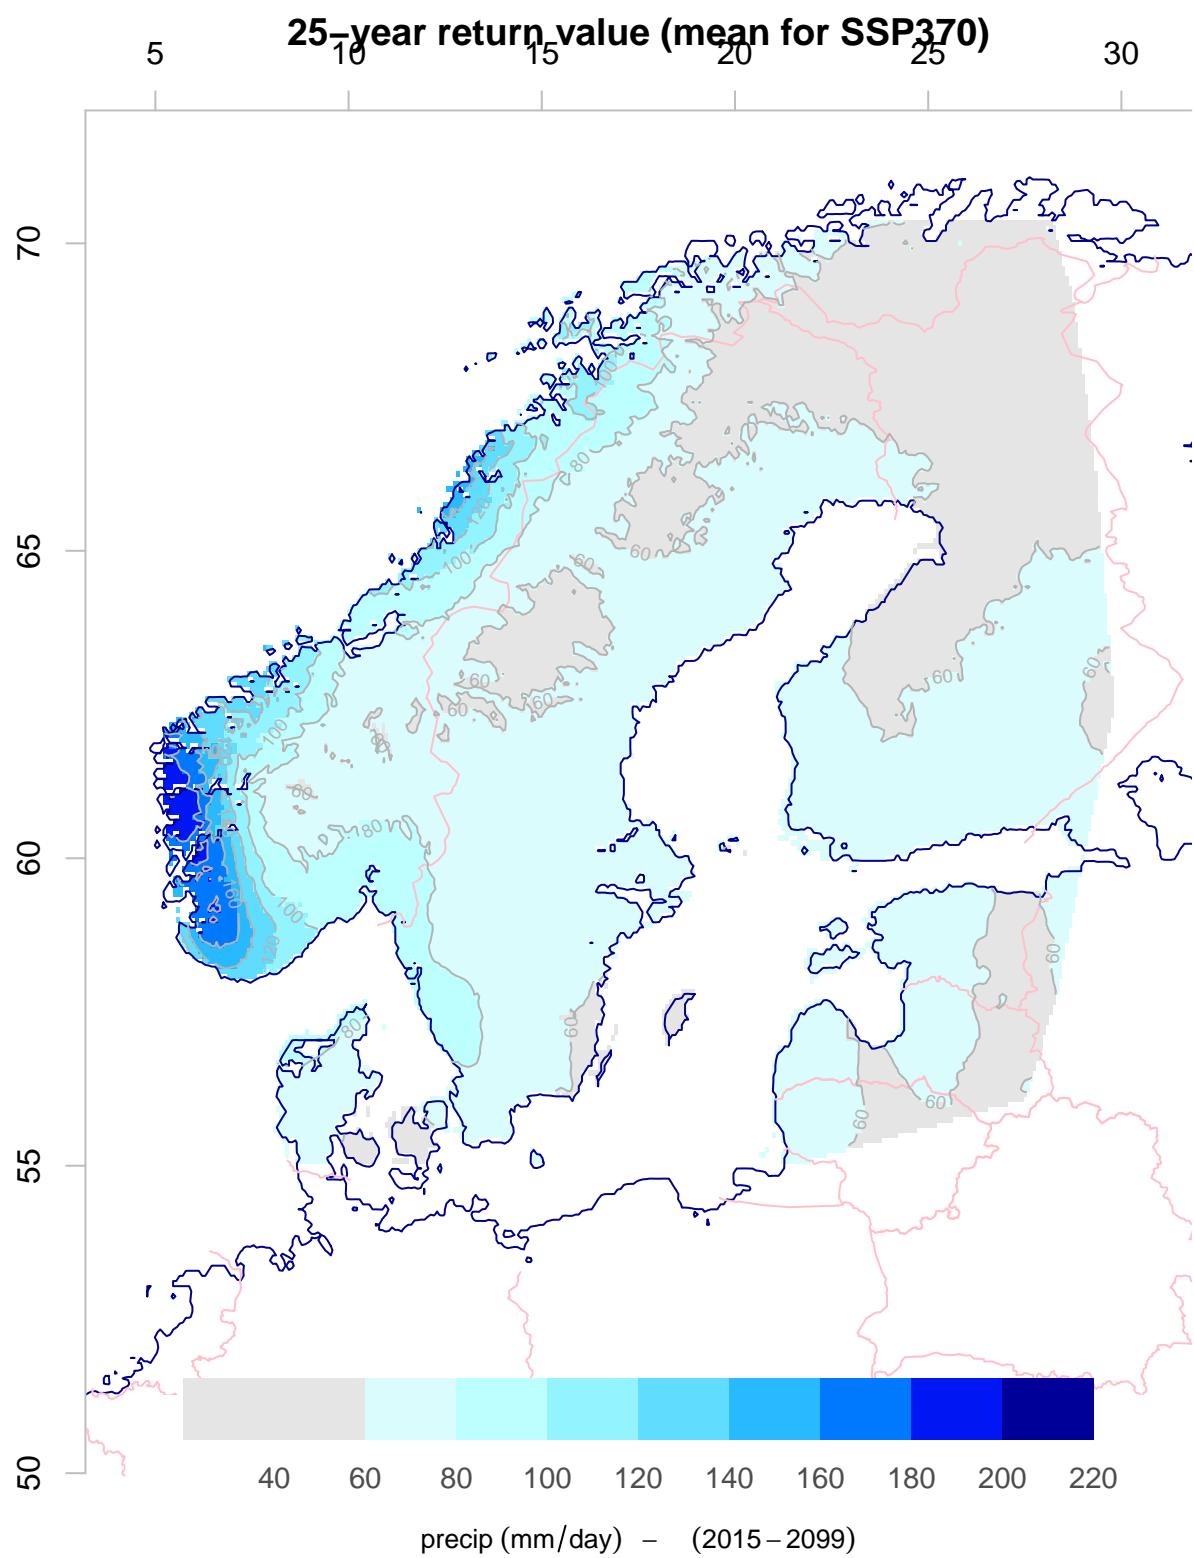

5 10 15 20 25 30 Trend in the 1-year return value (mean for SSP370)

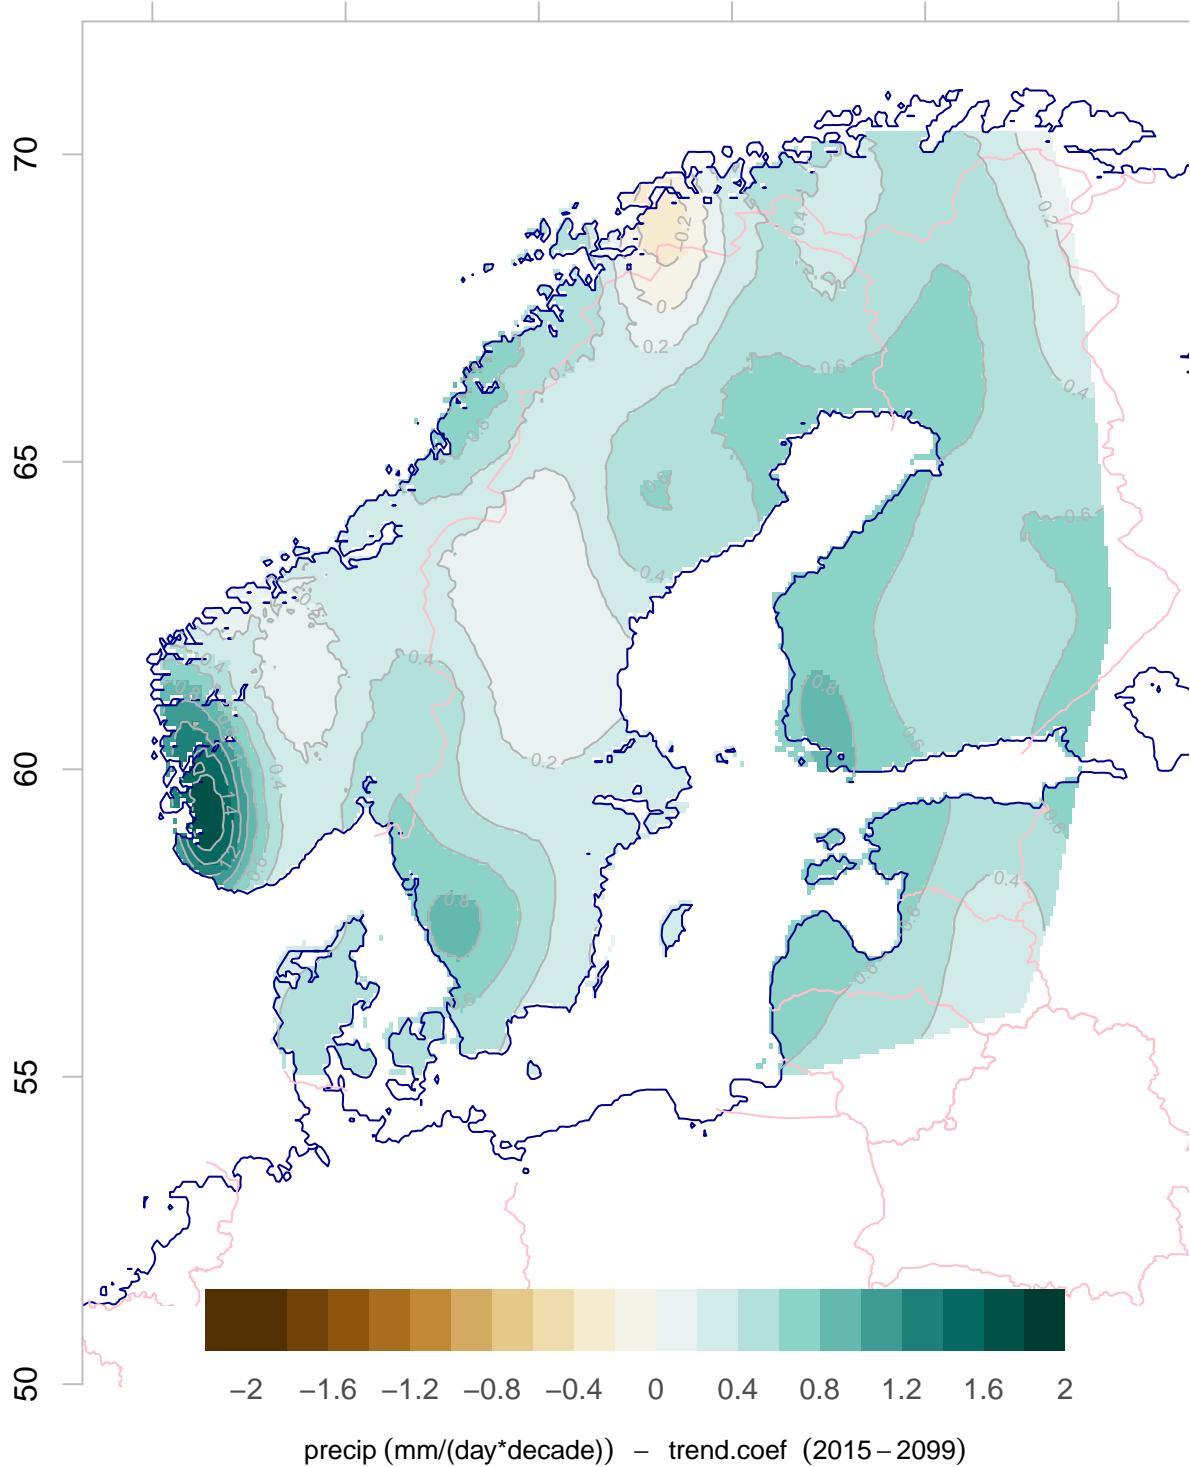

5 10 15 20 25 30 Trend in the 10-year return value (mean for SSP370)

Trend in the 25-year return value (mean for SSP370)

The spatial patterns of the mean 1-year, 10-year, and 25-year return values simulated for the 2015-2099 period and estimated on the basis of f_w and μ (SSP370) are very similar, but their magnitudes vary between ~100 mm, ~150 mm, and ~200 mm. The greatest magnitudes are seen along the west coast of Norway and the smallest magnitudes in over Finland.

3 Evaluatation of GCMs ability to reproduce large-scale f_w and μ

3.1 Evaluation of global climate models

One assumption behind downscaling is to utilise large-scale features that the global climate models (GCMs) can skilfully reproduce and the dependency of local scale climate upon these. Hence it's crucial to evaluate the GCM output to establish whether they skillfully reproduce real features, and in particular, it is important to evaluate how well the GCMs reproduce large-scale climate change and variability before using them as a basis for climate change adaptation. ESD can include some degree of evaluation, e.g. through the use of common empirical orthogonal functions, henceforth referred to as "common EOFs" (Benestad (2001)). This concept is explained more recently in Benestad (2021). Here, the acronym 'EOF' refers to 'empirical orthogonal functions' which are similar to principal component analysis and closely connected to the mathematical concepts known as eigenfunctions and eigenvalues.

Below is an analysis that provides an objective and deep evaluation of the predictors used to represent the large-scale conditions in downscaling as they are simulated by the GCMs, focusing on the most salient information embedded in the data. It goes beyond the framework suggested in Benestad (2001) by comparing large multi-model ensembles with a focus on the ensemble's ability to reproduce physical conditions such as the mean annual cycle, interannual variability and historical long-term trends, rather than emphasising individual members.

Another objective is to compare the evaluation of two generations of GCM simulations: CMIP5 and CMIP6. Here is a demonstration of how such a comparison can make use of the models' ability to reproduce the mean annual cycle, the interannual variability and historical trends over 1959-2021 in this case. The 63-year long period 1959-2021 is chosen because monthly ERA5 data are available in a single data set from 1950 until present time and because 2021 was the last year with complete data for all months at the time of the analysis.

More information about EOFs and common EOFs are available from <https://doi.org/10.1142/6908> and a short hands-on demonstration is available ads a YouTube <https://youtu.be/32mtHHAoq6k>.

The evaluation of GCM results based on common EOFs is implemented with the help of the R-package `esd` and similar to the analysis presented in Benestad et al. (2023). The following chunk activates it and sets the working environment

3.1.1 Special functions

The following code chunk defines a number of functions used in this analysis:

```
## Function to split the CMIP file names into model, ssp and RIPF
decipher <- function(x) {
  i <- gregexpr('_',x)[[1]]
  model <- substr(x,i[2]+1,i[3]-1)
  ssp <- substr(x,i[3]+1,i[4]-1)
  ripf <- substr(x,i[4]+1,i[4]+8)
  interval <- substr(x,i[5]+1,regexpr('.nc',x)[[1]]-1)
  return(c(model,ssp,ripf,interval))
}

## Method for calculating common EOFs of large multi-model ensembles with GCMs'
## mean annual cycle. Most of its operations involve preparation of the data and
## collecting the right data from multiple data files.
EOF.GCMsAC <- function(x,masked=FALSE,lon=NULL,lat=NULL,verbose=FALSE,...) {
  ## This function combines the annual cycles from different GCMs and performs a
  ## common EOF on the joint data
```

```

print('EOF.GCMsAC')
runs <- names(x)
runs <- runs[-grep('era5',runs)]
#print(runs)
if (length(grep('era5',names(x)))>0) X <- subset(x[['era5']],is=list(lon=lon,lat=lat))
if (masked) X <- mask(X,land=FALSE)
X <- regrid(X,is=list(lon=seq(min(lon(X)),max(lon(X)),by=1),
                        lat=seq(min(lat(X)),max(lat(X)),by=1)))
n <- length(runs)
for (i in 1:n) {
  if (verbose) print(runs[i])
  z <- subset(x[[runs[i]]],is=list(lon=lon,lat=lat))
  if (verbose) map(z)
  X <- combine(X,z)
}
## < Debugging >
#if (verbose) {print(str(X,max.lev=1)); print(names(attributes(X)))}
#for (j in 2:attr(X,'n.apps')) attr(X,paste0('appendix.',j)) <- NULL
#attr(X,'n.apps') <- 1
## > Debugging <
eof <- EOF(X,anomaly=FALSE,verbose=verbose,...)
invisible(eof)
}

## Method for calculating common EOFs of the GCMs' annually aggregated data
## Most of its operations involve preparation of the data and collecting the
## right data from multiple data files.
EOF.GCMsAM <- function(x,masked=FALSE,lon=NULL,lat=NULL,...) {
  ## This function combines the annual means from different GCMs and performs a
  ## common EOF on the joint data
  #print('EOF.GCMsAM')

3.2 Calculations

The following chunk of code is used for initialising the calculations. It contains some options (parameters) used for carrying out this analysis.

```

print('---<GCMSACAM.R>---')

## [1] "---<GCMSACAM.R>---"

par0 <- par()
plot <- TRUE
reprocess <- FALSE
outpath <- '~/R/'

paths <- c('~/data/CMIP5.monthly/', '~/data/CMIP6.monthly/')
run <- 'rii1p1f1|rii1p1'
bad.data <- NULL

```

3.2.1 Post- and pre-processing

The post-processing can be a bit time-consuming and the code therefore searches for results saved previously in the specified path. It will only carry out all the pre-processing if there is no data files with the expected file name.

```

print('Post-processing:')

## [1] "Post-processing:"

print(regions); print(paths)

## [1] "-5-45E.55-72N"

## [1] "~/data/CMIP5.monthly/" "~/data/CMIP6.monthly/"

for (ir in 1:length(regions)) {
  for (path in paths) {
    ssps <- list.files(path=path)
    ssps <- ssps[grep("RCP45|ssp245|hist", ssps)]
    for (ssp in ssps) {
      print(ssp)
      for (param in c('tas', 'pr', 'psl', 'fw', 'mu')) {

```

```

3.2.2 Diagnostics

The diagnostics involve calculating and plotting the common EOFs of the post-processed data. The plots of the common EOFs show the spatial pattern (upper left), the variance (based on the eigenvalues) associated with each pattern and the principal components (PCs) representing each GCM (red and darkgreen curves) and the ERA5 reanalysis (black curve). The two first figures show the common EOFs for the mean annual cycle whereas the next two show common EOFs of annual mean or seasonal maps in addition to one EOF analysis applied to trend maps for the historical period 1959-2021.

3.2.3 Wet-day frequency

```

When it comes to the wet-day frequency f_w the evaluations gave different results depending on the exact region. PC1 of the common EOFs for the mean annual cycle was surprisingly sensitive to modest variations in the selected geographical domain, especially for regions that included a large fraction of ocean it seems. A domain covering most of Europa gave a similar mean annual structure in PC1 for most CMIP6 models and ERA5, except for one GCM. The analysis indicates that one GCM is an outlier (CESM2-WACCM-FV2) and produced a mean annual shape distinct from the rest of the CMIP6 ensemble.

A smaller regional domain seemed to give a poorer match in the mean annual cycle covariance structure of f_w in the CMIP6 ensemble and ERA5. A mismatch in the mean annual cycle in f_w may be interpreted as a limitation of the models' ability to simulate changes. But the mean annual cycle was not resolved in the downscaling of annual f_w in the section above, although a limited representation of the mean annual cycle should underscore that the downscaled results have some caveats.

The common EOF evaluation suggested that the CMIP6 representation of interannual variations in annual f_w in general matched that of ERA5.

The common EOF of maps with trend coefficients for f_w (one map for each model run) suggested that the CMIP6 matched the long-term trends in f_w found in ERA5, albeit with a substantial scatter within the model ensemble.

```

Some of the grids in ERA5 and GCMs did not produce a single rainy day (threshold 1 mm/day) in some months and caused missing values (NA). This was a problem for dry regions, but when it happened for a rare occasion, the NA could be replaced with the mean value (`na2mean()`) to allow the EOF calculation to proceed.

The PCs for the seasonal cycle in μ had one outlier (CESM2-WACCM-FV2) compared to the rest of the ensemble for the chosen domain with large fraction of maritime environment. The analysis of the mean seasonal cycle and match between ERA5 and CMIP6 were sensitive to the geographical region selected for the common EOFs, but the interannual variability represented by the CMIP6 ensemble was generally consistent with that of ERA5.

A smaller geographical region suggested more similar mean annual cycle than a larger spatial domain, as well as a better match of the trend coefficients for μ . The analysis also indicated quite good match in the mean annual cycle over the Barents Sea and Arctic Norwegian Sea.

When the mean annual cycle in μ from the CMIP6 ensemble doesn't correspond to that in ERA5 it may

suggest that the models have a limited ability to simulate changes. The mean annual cycle was not resolved in the downscaling of annual μ in the section above, but a limited representation of the mean annual cycle should underscore that the downscaled results probably have some caveats.

The evaluation of trend coefficient maps suggested that ERA5 was mostly within the CMIP6 ensemble spread, and sometimes near the limits of the CMIP6 ensemble range.

These results suggest that it's important to use a suitable domain choice when using μ as predictor for empirical-statistical downscaling (ESD).

3.3.1 Figures for the manuscript

The following chunk shows how the figures in the manuscript were generated: Fig. 1. Station map Fig. 2. f_w and μ for Oslo. (1x2) Fig. 3. Maps of mean and tends in f_w and μ (2x2) Fig. 4. Precipitation trends and contribution from wet-days and intensity (3x) Fig. 5. Number of days with 30 mm (1). Fig. 6. Maps of $\text{Pr}(X>30\text{mm})$: mean, trend and relative trend (3x1). Fig. 7. Maps of mean and trend in 10-year and 25-year return values (2x2). Fig. 8. IDF curves.
