8

9 **Abstract**

10 Scientific meetings are vital for research development and networking. However, these
11 events often reflect unconscious biases and barriers to diversity, particularly affecting
12 ethnic minorities. The future success of geosciences depends on diversity, which
13 enhances problem-solving and innovation through varied perspectives. This study
14 examines the attendance diversity at the European Geosciences Union (EGU) General
15 Assembly from 2005 to 2024, focusing on the impact of economic factors, distance,
16 and population size on participation. Using publicly available data from the World Bank
17 and EGU, this study finds that gross national income (GNI) is the primary determinant
18 of attendance, especially post-COVID. Distance also influences attendance but to a
19 lesser extent, while population size shows a weak correlation. To improve diversity in
20 academic conferences, we suggest facilitating donations, offering affordable
21 accommodations, establishing additional travel funds, and rotating the conference
22 location. Our actions must go beyond the EGU General Assembly and other
23 geoscience conferences, as these actions can also help dismantle barriers to
24 inclusivity in other areas of our community. By addressing these financial and
25 systemic barriers, geoscience conferences can become more inclusive, benefiting the
26 entire scientific community.

27

28

1. Introduction

29 Academic conferences are crucial for researchers to promote their work,
30 establish new connections and collaborations through networking, and be informed of
31 the up-to-date research that is taking place across the globe. Such events are also
32 places where the identities of scientists are constructed and how scientists are
33 perceived within their community, often inadvertently reinforcing unconscious biases.
34 Scientific conferences tend to reproduce barriers to diversity in the geosciences,
35 meaning there is an underrepresentation of people from ethnic minorities and citizens
36 from developing nations (King et al., 2018; Talavera-Soza, 2023), who are therefore
37 more likely to face barriers to their career progress.

38 Diversity is essential to the future success of geoscience. As a community, we
39 tackle complex global problems that transcend artificial geographical boundaries
40 imposed by historical biases (Raja et al., 2022). Some of these problems, such as
41 natural resource depletion, disaster risk reduction, and climate change, are urgent,
42 and failure to tackle them will have dramatic negative consequences (Rogers et al.,
43 2022). Addressing these subjects requires scholars with diverse backgrounds,
44 including a representative mixture of cultures and ethnicities. Different perspectives
45 and life experiences lead to unique questions and approaches to problem-solving, and
46 inspire more creative alternatives to relevant challenges, ultimately leading to higher
47 levels of scientific innovation (Medin and Lee, 2012; Hong and Page, 2004).

48 Within this context, scientific meetings play an important role in bringing
49 together and promoting knowledge exchange among scholars from diverse
50 backgrounds. But how diverse are geosciences meetings? Here, we probe into
51 attendance figures for Europe's largest geoscience meeting, the European
52 Geosciences Union (EGU) General Assembly, held in Vienna (Austria) since 2005.
53 We selected EGU because it integrates all geosciences subjects and ranks among the
54 biggest international conferences in the world with participants from over 110
55 countries. Using publicly available historical data (EGU, 2024), we highlight the
56 persistence of economic factors as the primary control for conference attendance (Fig.
57 1). From our perspective of participating in the 2024 EGU assembly, we note that while
58 the theme of Equality, Diversity, and Inclusion (EDI) is significantly featured in the
59 conference program, the actual diversity observed falls short of ideal standards.

60

61 **2. Dataset and Methodology**

62 We examine geographical diversity and representation at the EGU General
63 Assembly (hereafter referred to as the *EGU meeting, assembly, or conference*), one
64 of the largest geosciences meetings in the world. For each country, we analyze
65 attendance figures from 2005 to 2024 relative to three variables: (i) distance to the
66 event, (ii) gross national income (GNI) per capita, and (iii) population size. We chose
67 distance to assess whether geography was the principal driver of attendance variability
68 and GNI to assess the impact of income on participation. Given the lack of precise
69 demographic data on the number of geoscientists per country, we use population as
70 a proxy assuming the rate of geoscientists per capita is the same. All demographics
71 are publicly available and derived from the World Bank and EGU's website (EGU,
72 2024 – see supplementary data). We favor these metrics because they are simple and
73 not codependent/derived from each other (e.g., the human development index and
74 Henley passport index, which derive from a series of political and economic factors).
75 Because the selected metrics vary over several orders of magnitude, we calculate the
76 Spearman's rank correlation coefficient (ρ) rather than a linear regression to examine
77 their relative impact on EGU's conference participation.

78 Additionally, to avoid post-COVID biases in travel patterns and truthfully
79 represent historical attendance trends, we exemplify these relationships using data
80 from the last pre-COVID edition of EGU's meeting (2019). In addition to correlation
81 coefficients, we compute income-independent over- and underrepresentation by
82 dividing the normalized attendance by the product of population and the distance to
83 the conference.

84

85 **3. Results**

86 **3.1. Gross national income over time**

87 Over the years, EGU's assembly attendance exhibits a strong correlation GNI,
88 as illustrated in Figure 1, where the correlation coefficient (ρ) typically exceeds 0.6.
89 Notably, these correlation values have consistently been significant at the 99%
90 confidence level (they are between 10^{-8} to 10^{-13} , below the minimum value for the y-

91 axis in Fig. 1b), demonstrating remarkable stability throughout the EGU meeting's
92 history. This strong relationship between attendance and income is only disrupted by
93 countries with large populations, such as China and India (Fig. 2b). In other words,
94 these countries exhibit higher-than-expected participation based on their GNI values.
95 While there has been a decreasing trend in the correlation between attendance and
96 GNI since the inception of the EGU assembly (2005) until 2015; from the latter half of
97 the 2010s (2015 until 2024) there is a reversal of this trend, with a notable increase in
98 the correlation between attendees and GNI. Post-COVID metrics (2022 to 2024)
99 reveal the strongest correlation ever recorded, with a ρ exceeding 0.8. In the virtual
100 versions of the event (held from 2020 onwards), this correlation between attendance
101 and GNI is less strong ($\rho < 0.6$; Fig. 1a).

102

103 3.2. Distance to conference site over time

104 The impact of distance to the conference site on attendance emerges as a
105 secondary factor, with low correlation coefficients typically hovering around 0.35 (Fig.
106 1). Although this correlation is relatively weak, it remains stable and statistically
107 significant at the 99% confidence level over the years. Despite its independent
108 influence, distance often interacts with GNI as a combined socioeconomic limiting
109 factor, since individuals from more distant countries have higher travel expenses. This
110 pattern is disrupted by distant, wealthy countries, such as Australia, Japan, and New
111 Zealand, which have all maintained robust participation throughout EGU assembly's
112 history (Fig. 2a). In virtual versions of the event, distance shows the weakest
113 correlation with attendance (Fig. 1a, $\rho < 0.4$).

114

115 3.3. Population over time

116 In contrast to gross national income, the total population of a country typically
117 shows a poor correlation with attendance for the majority of EGU assembly's history,
118 with ρ values consistently below 0.3 from 2005 to 2017 (Fig. 1). Despite that, there
119 has been a steady increase in the correlation coefficient for population until 2018, with
120 2015 marking the first instance of statistical significance at the 99% confidence
121 interval. This is particularly noticeable by examining the change in attendance figures

122 for populous countries such as India, China, and Indonesia during a 10-year pre-
 123 COVID period (2009-2019; Fig. 2). Nonetheless, post-COVID figures for 2022 to 2024
 124 indicate a significant drawback in this correlation, as evidenced by a ρ below 0.2,
 125 representing the lowest value ever recorded in EGU assembly's history. In the virtual
 126 versions of the assembly, held between 2020 and 2024, the population shows a
 127 stronger correlation ($\rho \sim 0.4$) when compared with the in-person format of the event (ρ
 128 < 0.2).

129
 130 **Figure 1.** Correlation between the EGU General Assembly participants and distance to the conference,
 131 total population, and GNI per capita. (a) Spearman's rank correlation coefficient (ρ) and (b) their
 132 respective significance (p-values); whenever a p-value is not visible it indicates that the p-value $< 10^{-5}$
 133 (p-values for the GNI correlation are between 10^{-8} to 10^{-13}).

134

135

136 **Figure 2.** EGU's General Assembly attendance for the last pre-COVID meeting in 2019. a, participation
 137 vs. distance to the conference; b, attendance vs. Gross national income per capita. Gray shading
 138 regions in b denote 95% confidence intervals for a best-fit power-law regression of the data.

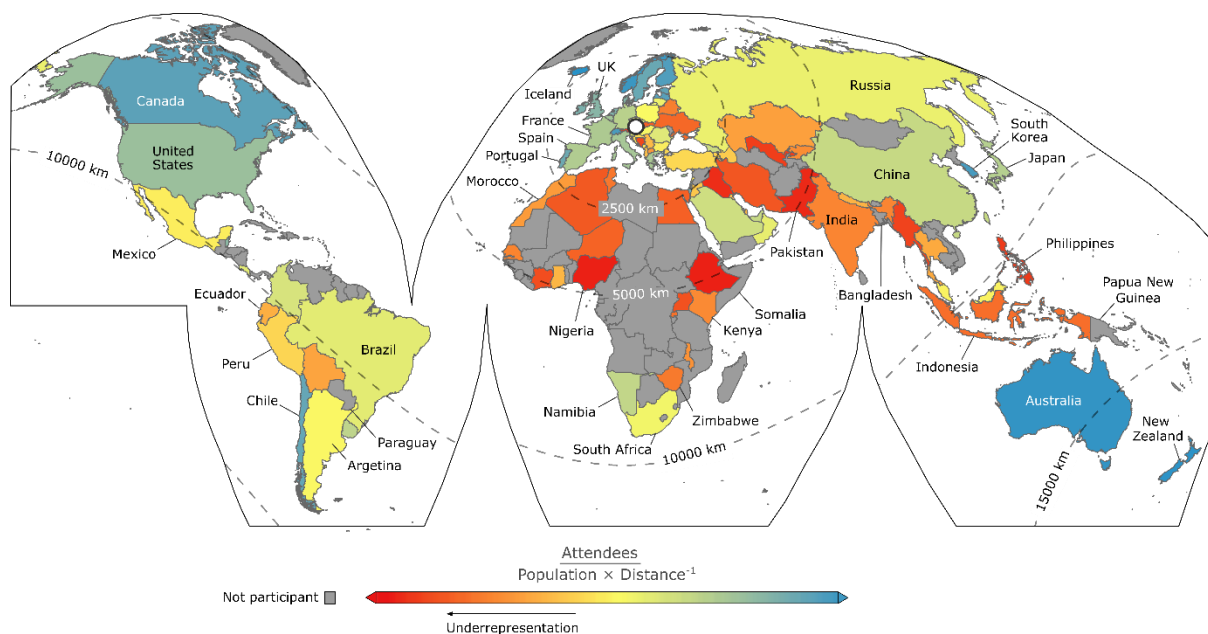

139

140 **4. What controls the in-person EGU assembly participation?**

141 Based on the variables investigated here, our results indicate that attendance
 142 at EGU's General Assembly is primarily and consistently controlled by income metrics
 143 (GNI), with the strongest correlation ever recorded in the past three years (Fig. 1,
 144 2022-2024). Distance to the conference site also influences attendance, albeit with a
 145 weaker correlation. In contrast, a country's total population has historically shown a
 146 poor correlation with attendance (Figs. 1 and 2).

147 When comparing countries with similar populations and distances to the
 148 conference site, it becomes evident that income stands out as the main influencing
 149 factor in attendance (Fig. 2a). Nations with similar distances to the conference tend to
 150 exhibit higher participation rates with increasing GNI (Fig 2a). Examples include, from
 151 lower to higher GNI, Pakistan, South Korea, and the USA. This pattern is disrupted by
 152 populous countries such as India and China. Similarly, a similar trend is observed
 153 among countries with comparable populations. For instance, Ethiopia and the
 154 Philippines have significantly fewer participants compared to Japan (Fig 2b). In this
 155 context, our compilation reveals that attendance is dictated by a power-law
 156 relationship with income, with wealthier nations having two to three orders of
 157 magnitude more participants than poorer countries (Fig. 2b).

158 Under an income-independent participation scenario, participation would
 159 depend on distance and population. To identify the impact of income, the map in Figure
 160 3 shows the relative representation of each country in the EGU assembly of 2019 after
 161 normalizing for distance and population. Notably, countries in Europe, northern North
 162 America, and Oceania (the Global North) exhibit the highest representation. Not
 163 coincidentally, these are the countries with the highest GNI per capita values (Fig. 2b;
 164 World Bank, 2024). Conversely, numerous countries in Latin America, Africa, and Asia
 165 are moderately to highly underrepresented in the conference. Based on correlation
 166 metrics (Fig. 1) and attendance plots (Fig. 2a), the distance from the conference venue
 167 can be ruled out as the primary reason behind representativity. From a global
 168 perspective (Fig. 3), curves of equidistance reveal that countries located at
 169 comparable distances from Austria present varying levels of representation. For
 170 instance, despite all being approximately 7,500 km away, India and nations in central
 171 Africa are notably underrepresented, while Canada stands out as overrepresented in
 172 conference attendance (Fig. 3). Additionally, Australia, despite being one of the most
 173 distant countries from Austria, maintains a high level of representation in the event
 174 (Figs. 2b and 3).

175
 176 **Figure 3.** Representation attendance map for EGU General Assembly 2019 corrected for both distance and
 177 population. Dashed lines represent the distance to EGU's conference site in Vienna, Austria.

178 Ultimately, attendance in the in-person EGU assembly is largely controlled by
 179 income. With registration fees ranging from €525 to €765 for non-students in 2024, the

180 economic burden varies significantly across countries. For instance, in our home
181 country Brazil, registration costs can amount to nearly three times the monthly
182 minimum wage, or about half the monthly wage of a full professor (World Salaries,
183 2024). In African nations like Angola, Nigeria, and the Democratic Republic of Congo,
184 fees can exceed ten times the monthly minimum wage, or roughly twice to three times
185 the monthly wage of a full professor (World Salaries, 2024). In contrast, in Canada,
186 fees equate to roughly half of the monthly minimum wage, or about one-tenth of the
187 monthly wage of a full professor (World Salaries, 2024). In addition, travel expenses
188 are generally much higher than registration fees, which are only a fraction of the total
189 cost. Additional expenses including transportation, accommodation, and meals, priced
190 in the local currency (euros), significantly add to the overall financial commitment of
191 participation.

192 Another significant barrier to in-person attendance for researchers from
193 developing countries, countries with less political stability, and nations facing
194 geopolitical tensions, is the challenge of obtaining a visa to enter Austria. The process
195 is often both costly and time-consuming, often requiring extensive paperwork, letters
196 of support, and sometimes in-person appointments which may involve travel costs.
197 Scientists from countries like Iran, Afghanistan, Yemen, and Bangladesh frequently
198 face more stringent visa requirements and higher rejection rates compared to those
199 from countries like Canada, Australia, or Japan (Passport Index, 2024). To address
200 this issue, the EGU has implemented measures to support visa applications by
201 providing detailed invitation letters (EGU, 2024).

202

203 **5. What can be done about it?**

204 It is clear that the European Geoscientists Union (EGU) acknowledges the
205 importance of diversity and is actively working towards a more equitable future. In
206 2018, the EGU Council established an equality, diversity, and inclusion (EDI)
207 Committee to raise awareness and promote EDI initiatives (EGU, 2024b). Similar
208 efforts have been observed in other geoscience conferences and societies. For
209 instance, the American Geophysical Union Meeting, the world's largest geoscience
210 conference, also adopted a Diversity & Inclusion Strategic Plan in 2018 (AGU, 2024).
211 The Geological Society of London has recently established a new Equity, Diversity,

212 Inclusion and Accessibility Committee in 2024 (The Geological Society of London,
213 2024).

214 Additionally, since the COVID-19 pandemic in 2020, the EGU introduced a
215 virtual version of the meeting. This version offers lower fees, and free enrollment for
216 (i) undergraduate or master students and (ii) low- & lower-middle-income countries.
217 These initiatives are readily observed in correlation metrics for the virtual version of
218 the EGU assembly, which show record-breaking increased ranked correlation (ρ) for
219 population and decreased ρ for GNI and distance (Fig. 1a). Clearly, the virtual event
220 increased accessibility and diversity by reducing the cost. However, in our and others'
221 personal experience, the virtual event shows limited engagement and interaction with
222 presentations and reduced networking opportunities between attendees. Furthermore,
223 the EGU offers financial assistance to encourage participation in the in-person event.
224 The Roland Shlich travel support includes a waiver of registration fees, reimbursement
225 of the abstract processing charges, and travel expenditure aid up to €300. Even
226 though this initiative is commendable and impactful, the overall cost of attending
227 remains prohibitive for scholars from low-income countries.

228 To increase diversity at events like the EGU assembly and other geoscience
229 events, we must alleviate financial barriers for attendees from lower-income countries.
230 Here we explore some possibilities to achieve that goal. Firstly, establish a dedicated
231 travel fund aimed at supporting attendees from lower-income countries and
232 underrepresented regions (Fig. 3). This fund could help cover visa costs and offset
233 exchange rate disparities. It could be financed through donations from attendees,
234 companies, universities, and patrons. Secondly, consider rotating the conference's
235 host country within Europe, making it more accessible to participants from various
236 regions. Besides changing the distance to other countries outside of Europe, costs of
237 accommodation and meals vary significantly across European countries (ranging from
238 approximately €36 to €136 per day; Price of Travel, 2024). Lastly, facilitate affordable
239 accommodation options for scholars from lower-income countries through
240 partnerships with hotels and hostels, or university housing.

241 Our discussion around increasing diversity and representation cannot be limited
242 to the EGU General Assembly or geoscience conferences in general; rather, it must
243 extend to acknowledging how conference attendance perpetuates barriers to

244 inclusivity within our community. The attendance patterns in the EGU assembly
245 highlight the prevalence of the Global North countries, which reflects the historical
246 dominance of these societies in shaping the field of geosciences until the present.

247 Ethnic and cultural underrepresentation not only hinders the career
248 advancement of marginalized groups but also underscores the persistent dominance
249 of the Global North in many scientific fields, including geosciences (Rogers et al.,
250 2022; Raja et al., 2022). Academic neo-colonialism is not only reflected in conference
251 participation patterns, but it also extends to the selective prestige accorded to
252 universities and journals and the imposition of curricula, educational systems,
253 languages, and epistemologies on formerly colonized societies (Nagtegaal and de
254 Bruin, 1994; Rogers et al., 2022).

255 To promote equal research opportunities and equitable conference attendance,
256 structural changes are necessary. We need to recognize and praise the true
257 achievements and potential of scholars from outside the Global North. North-South
258 scientific collaborations must become more symmetrical and founded on mutual
259 respect, ensuring that knowledge production is collaborative, rather than extractive
260 (Jeffrey, 2013; North et al., 2020; Rogers et al., 2022; Garland et al., 2024). Funding
261 disparities ought to be tackled by the development of multi-partner and multi-national
262 co-funded research projects (Jeffrey, 2013). Biases inherent in the peer review
263 process of both papers and grant applications must be acknowledged and addressed
264 (Rogers et al., 2022). Geoscience conferences need to be accessible to all, allowing
265 scholars from underrepresented regions to share their research and perspectives, and
266 to expand their networking opportunities. By recognizing and valuing the contributions
267 of scientists from diverse backgrounds, we can move towards a more inclusive and
268 equitable scientific community.
