S1 HPMTF detection, calibration, and uncertainty

The Vocus AIM sampled from a 4 m inlet height, roughly 1 m above the top of the trailer, through a 4.5 m long 1/2" O.D., 11 mm I.D. PFA tube. The full inlet tube was pumped at 10 lpm, resulting in an inlet residence time of about 2.6 s. The in-field
20 I•H₂O:I⁻ ratio was 0.97 ± 0.06 for iodide reagent ion mode on the Vocus AIM. The formic acid sensitivity at an I•H₂O:I⁻ ratio of 0.97 was 4.55 ncps ppt⁻¹, normalized per million of reagent ion counts, and determined via humidity-dependent formic acid calibrations on this instrument. The instrument's sensitivity to formic acid was expected to be a reasonable approximation for its sensitivity to HPMTF, as the iodide adduct binding enthalpies for HPMTF and formic acid are similar (-25.05 kcal mol⁻¹ for HPMTF and -25.52 kcal mol⁻¹ for formic acid) (Iyer et al., 2016; Jernigan et al., 2022a). The mass resolution ($m/\Delta m$) of
25 the Vocus AIM was ~5500, which allowed for separation of HPMTF ([C₂H₄SO₃•I]⁻, 234.8931) from other ions at the same nominal mass, (234.8655, 234.9109 (suggested as [CH₃COOH•IO₃]⁻), 234.9434, and 234.9811). The exception was N₂O₅•I⁻ (234.8857), though the potential contribution of this ion on the presented analysis was estimated as minimal (see main text).

We tested the validity of the HPMTF calibration factor by comparing clear sky measurements of HPMTF to a chemical box
30 model developed in F0AM. This comparison was completed for July 11, 2022, where the mean and standard deviation in CF₃A (Hr. 6-17) were 0.065 ± 0.055 and the mean and standard deviation in DMS over the entire day were 45 ± 31 ppt. The box model was constrained by observed meteorological conditions and trace gas measurements on this day. A DMS flux was specified to match the day's average measured DMS concentration. This comparison indicates that the reported HPMTF concentrations, calibrated with formic acid, are a lower limit, and could underrepresent ambient HPMTF concentrations by up

35 to 60% (Fig. S1). The model-measurement disagreement in absolute HPMTF concentrations arises from uncertainty in the calibration factor and inlet loss of HPMTF. Given the ambient relative humidity was always greater than 50%, and typically much higher (campaign mean and standard deviation of $80\pm 8\%$), and the ICIMS $\text{I}\cdot\text{H}_2\text{O}:\text{I}^-$ ratio was relatively constant, we expect uncertainty in HPMTF provides a systematic error. This means that trends reported here with 3-dimensional cloud fraction are expected to be robust.

50

Figure S1: Measurements of HPMTF, calibrated with the formic acid calibration factor, on July 11th are shown with dots. The modelled HPMTF concentration, in red, for a clear sky model constrained by measurements on July 11th. Measured HPMTF could be underestimated by 60%, due to a combination of calibration factor uncertainty and inlet loss.
