20 **Abstract:** Secondary organic aerosols (SOA) from highly volatile organic compounds  
21 (VOCs) are currently not well represented in numerical models as their heterogeneous  
22 formation mechanisms in the atmosphere remain unclear. Based on the smog chamber  
23 experiments, here we investigated the yield and formation pathway of SOA from acetone  
24 photochemical reactions in the presence of preexisting haze particles ((NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>, and  
25 NH<sub>4</sub>HSO<sub>4</sub>) and mineral dusts (Na<sub>2</sub>SO<sub>4</sub>) under ammonia-rich conditions. Our results showed  
26 that the yield of acetone-derived SOA is remarkably enhanced via multiphase reactions in  
27 the presence of these preexisting seeds especially for the mineral dusts. We found that  
28 aerosol acidity is a key factor controlling the formation pathways of acetone-derived SOA,  
29 in which organic acids, alcohol and carbonyls produced from acetone photochemical  
30 reactions dissolve into the aqueous phase of the preexisting seeds and subsequently esterify  
31 and/or oligomerize into SOA that consist of larger molecules on the acidic aerosols but  
32 smaller molecules on the neutral mineral aerosols. Moreover, light absorption ability of the  
33 acetone-derived SOA formed on (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> aerosols is stronger than that formed on Na<sub>2</sub>SO<sub>4</sub>  
34 mineral particles especially in the presence of ammonia due to a formation of N-containing  
35 organics. By comparing with that from methylglyoxal (MGly), we found that the total SOA  
36 from acetone in the chamber is 2.8–8.2 times that from the irreversible uptake of MGly,  
37 suggesting that only considering MGly as the precursor of acetone-derived SOA will  
38 probably underestimate the role of acetone in the global SOA production since acetone  
39 abundantly exists in the troposphere.

41 Polymerization; Aerosol acidity.

42

## 43 **1. Introduction**

44 Secondary organic aerosols (SOA) are the major component of fine particles in the  
45 atmosphere and produced from the photochemical oxidation of volatile organic compounds  
46 (VOCs) (Zhang et al., 2015a; Srivastava et al., 2022; Wang et al., 2016b), which  
47 significantly affects human health and global climate change (Jo et al., 2023; Chowdhury et  
48 al., 2022). However, current numeric models cannot predict the evolution of atmospheric  
49 SOA accurately; one of reasons is that models often only consider the partitioning process of  
50 condensable oxidation products of VOCs as the major formation pathway of SOA and  
51 neglect the contribution of heterogeneous reactions of highly volatile VOCs to atmospheric  
52 SOA (Heald et al., 2005; Li et al., 2023).

53 A number of researchers have reported that SOA formation can be promoted  
54 significantly in the presence of hydrated seeds by heterogeneous reactions (Wong et al.,  
55 2015; Nguyen et al., 2014; Liu et al., 2018; Ge et al., 2017). For instance, Wong et al. (2015)  
56 reported that more isoprene SOA was formed on deliquescent ammonium sulfate seeds in  
57 comparison with that on the efflorescent ones. Such an enhancing effect of multiphase  
58 chemistry on SOA formation has also be found by Liu et al. (2018) and Wang et al. (2022) in  
59 their laboratory experiments. Their results showed that SOA multiphase formation is  
60 affected by the aerosol liquid phase properties such as acidity, ionic strength and mixing  
61 state, which can alter the gas-to-particle phase partitioning of VOC and change the  
62 formation process of SOA (Zhang et al., 2023; Riva et al., 2019; Riva et al., 2016; Bateman  
63 et al., 2014; Kampf et al., 2013; Wei et al., 2022). Amorim et al. (2020) analyzed the OH  
64 reactivities of organic acids in aqueous phases with different pH, and found that all the  
65 [organic acids](#) exhibited larger OH reactivities under basic conditions than those under acidic  
66 conditions, indicating that aerosol acidity can influence the gas-particle partitioning and the  
67 multigeneration oxidation of volatile organics in liquid phase (Wei et al., 2022; Amorim et  
68 al., 2021; Amorim et al., 2020; Zhao et al., 2006; Lv et al., 2022). [Moreover, a few studies](#)  
69 [reported that the uptake of VOC oxidation products by inorganic aerosols can be affected by](#)  
70 [a salting-in/salting-out effect \(Waxman et al., 2015; Wang et al., 2016a\).](#) These results  
71 [suggest that heterogeneous reactions of VOCs are important sources of atmospheric SOA,](#)

72 which are complex and affected by many factors. Currently, only a limited number of  
73 volatile organics, such as glyoxal, methylglyoxal (MGly), formaldehyde and epoxydiols,  
74 have been investigated by chemical transport models for their contribution to the  
75 atmospheric SOA through heterogeneous reactions (Heald et al., 2005; Li et al., 2023; Fu et  
76 al., 2008; Moch et al., 2020). While the role of heterogeneous reactions in SOA formation  
77 from many other more volatile organics in the atmosphere is still unclear and is ignored  
78 generally by model work.

79 Compared to glyoxal, MGly and formaldehyde, acetone is much more volatile, which is  
80 of a Henry's law constant ( $K_H$ ) being 2–4 orders of magnitude lower than the three species  
81 and abundantly exists in the atmosphere from the ground surface to the upper troposphere  
82 (Seinfeld and Pandis, 2006). Acetone can be directly emitted from the natural and  
83 anthropogenic sources and indirectly produced from oxidation of hydrocarbons (Jacob et al.,  
84 2002; Wang et al., 2023). A laboratory experiment showed that deliquesced inorganic  
85 aerosols may promote SOA formation from the photochemical oxidation of acetone  
86 significantly (Ge et al., 2017), but up to now the yield of SOA derived from acetone  
87 photochemical reactions and the impact of inorganic aerosol physicochemical properties on  
88 SOA formation from acetone have not been reported. Therefore, the formation mechanism  
89 and the importance of acetone-derived SOA in the atmosphere remain unclear, where  
90 acetone ubiquitously co-exists with  $\text{NH}_3$  and preexisting aerosols. MGly is an important  
91 product of acetone photochemical reactions with 14% molar yield, which can partition into  
92 aqueous phase followed by oligomerization, oxidation by OH or/and reaction with  $\text{NH}_3$  or  
93 organic amine to form SOA (De Haan et al., 2019; Aiona et al., 2017; Li et al., 2021b;  
94 Yasmeen et al., 2010; Zhang et al., 2022). Currently, estimation of acetone-derived SOA by  
95 chemical transport models only consider its product MGly as the SOA precursor (Fu et al.,  
96 2008). However, Ge et al. found that other products derived from acetone photo-oxidation  
97 such as alcohols and organic acids also can dissolve into the aqueous phase and transform  
98 into SOA by esterification (Ge et al., 2017), indicating that only considering the uptake of  
99 MGly will probably underestimate the contribution of acetone to the global SOA production.  
100 Thus, it is necessary to investigate the SOA formation from acetone and compare it with

101 MGly-SOA.

102 In this work, we quantitatively investigated the effects of deliquescent seeds and NH<sub>3</sub>  
103 on SOA formation from the photochemical reaction of acetone via chamber experiments,  
104 and compared the difference of SOA formation processes in the presence of different seed  
105 particles. We for the first time revealed a key role of seed acidity in controlling the yield and  
106 formation pathways of SOA from acetone photochemical reactions, in which NH<sub>3</sub> and dust  
107 particles can greatly enhance the production and light absorption of acetone-derived SOA.

## 108 **2. Experiments section**

### 109 **2.1 Materials and methods**

110 All batch mode experiments in this study were performed in a 4 m<sup>3</sup> sealed Teflon smog  
111 chamber (Figure S1). Firstly, zero air and seed particles were introduced into the chamber.  
112 Then, acetone, H<sub>2</sub>O<sub>2</sub> and NH<sub>3</sub> were introduced sequentially for the heterogeneous reactions.  
113 The experiment details are reported by our previous studies (Ge et al., 2019; Zhang et al.,  
114 2021; Liu et al., 2021a).

115 Briefly, zero air produced by the Zero Air Supply (Model 111 and Model 1150, Thermo  
116 Scientific, USA) was used as the background gas in this study. Saturated water vapor flow  
117 produced by bubbling zero air through ultrapure water (Milli Q, 18.2 MΩ, Millipore Ltd.,  
118 USA) was introduced into the chamber for adjusting the relative humidity (85±1.0% RH).  
119 Three types of water-solutions containing Na<sub>2</sub>SO<sub>4</sub>, (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and NH<sub>4</sub>HSO<sub>4</sub> were nebulized  
120 to produce seed particles. A polydisperse mode of wetted inorganic aerosols was generated  
121 from the solutions by using a single jet atomizer (7388SJA, TSI) and directly introduced into  
122 the chamber as droplets without any dessication. Reactant gases including acetone, H<sub>2</sub>O<sub>2</sub>,  
123 NH<sub>3</sub> and SO<sub>2</sub> were added separately into the chamber along with a N<sub>2</sub> flow using a glass  
124 syringe (Liu et al., 2022; Liu et al., 2021b).

### 125 **2.2 Smog chamber experiments and characterization**

#### 126 **2.2.1. Smog chamber experiments**

127 In this study, the chamber experiments can be divided into two phases: Phase I, SOA  
128 formation from the [photochemical oxidation and photolysis of acetone](#) on aerosols was  
129 investigated, in which the OH radicals were produced from the photolysis of H<sub>2</sub>O<sub>2</sub> under 254

130 nm UV irradiating conditions; Phase II, the effect of  $\text{NH}_3$  on SOA formation was explored  
131 under dark conditions. The  $\text{H}_2\text{O}_2$  concentrations injected into the chamber were  $2.95 \times 10^{13}$   
132 molecules  $\text{cm}^{-3}$  in all experiments. The influence of different inorganic particles on the two  
133 phases were studied. To compare the influence of different inorganic particles on the SOA  
134 formation,  $\text{SO}_2$  was added into the chamber after Phase II to produce  $(\text{NH}_4)_2\text{SO}_4$  aerosols  
135 during the  $\text{Na}_2\text{SO}_4$  seed experiments. All the experiments were conducted under  $85 \pm 1.0\%$  RH  
136 conditions and thus all the seeds in the chamber were deliquescent. At the end of each  
137 experiment, aerosol in the chamber were collected on 47 mm quartz filters and stored at  
138  $-20^\circ\text{C}$  prior to analysis. The initial experimental conditions were displayed in Table S1.

### 139 **2.2.2. On-line monitoring**

140 RH and temperature inside the chamber were monitored online. The temperature in the  
141 chamber was stabilized at  $25 \pm 1^\circ\text{C}$  by using air conditioners. Concentrations of VOCs and  
142  $\text{SO}_2$  in the chamber were monitored by a proton transfer reaction time-of-flight mass  
143 spectrometer (PTR-TOF-MS, Ionicon Analytik, Innsbruck, Austria) and a  $\text{SO}_2$  analyzer  
144 (Model 43i, Thermo scientific), respectively. Size distribution and mass concentration of  
145 aerosols during the reaction process were measured by a scanning mobility particle sizer  
146 (SMPS, model 3082, USA). The real-time chemical composition evolution of aerosols in the  
147 chamber was measured by a high-resolution time-of-flight aerosol mass spectrometer (HR-  
148 ToF-AMS, Aerodyne Research Ltd, USA), which was operated on a high sensitivity V-mode  
149 with a 30 s time resolution. Prior to the experiments, ionization efficiency of the AMS was  
150 calibrated by using 300 nm  $\text{NH}_4\text{NO}_3$  particles and the value was  $5.01 \times 10^{-8}$ , and the relative  
151 ionization efficiency (RIE) for ammonium was 4.6. The RIE for sulfate was calibrated using  
152  $(\text{NH}_4)_2\text{SO}_4$  particles, and the value was 0.8.

153 Particle wall loss in the chamber was corrected using a total-mass-concentration-based  
154 method and the detailed descriptions were shown in Text S1 (Liu and Abbatt, 2021; Zhang et  
155 al., 2024). The wall loss of  $\text{NH}_3$  and VOCs in the chamber was also corrected (see the details  
156 in Text S2 and S3) (Li et al., 2021a; Huang et al., 2018; Zhang et al., 2015b). Aerosol liquid  
157 water content (ALWC) was estimated using the E-AIM thermodynamic model IV, and the  
158 pH values of aerosols were calculated by Eq.1.

$$\text{pH} = -\log_{10} (\gamma_{\text{H}^+} m_{\text{H}^+}) \quad (1)$$

159 Where  $\gamma_{\text{H}^+}$  and  $m_{\text{H}^+}$  were the activity coefficient and molality of  $\text{H}^+$  calculated by E-AIM  
160 model, respectively.

### 161 **2.2.3. Off-line analysis of particles**

162 The collected samples were extracted with 15 mL of Milli-Q pure water in an ultrasonic  
163 bath for 30 min, and filtered by a 0.45  $\mu\text{m}$  PES syringe filter. The concentration of water-  
164 soluble organic carbon (WSOC) and light absorption of the extracts were analyzed by a total  
165 organic carbon analyzer (model TOC/TN-LCPH, Shimadzu Inc. Japan) and a liquid  
166 waveguide capillary cell (model LWCC3000, Ocean Insight. USA) coupled with a UV/Vis  
167 spectrophotometer (ocean insight) over a wavelength range of 200–900 nm, respectively.  
168 Light absorption ( $\text{Abs}_\lambda$ ) and mass absorption coefficient (MAC) of the water extracts were  
169 calculated (see the details in Text S4). In addition, the collected particles were extracted with  
170 pure methanol and analyzed for their chemical compositions using an ultrahigh-resolution  
171 orbitrap mass spectrometer (Q-Exactive Orbitrap mass spectrometer, Thermo Scientific,  
172 Germany) (Jia et al., 2023). Specifically, imidazole compounds (IMs) were determined using  
173 the orbitrap-mass spectrometry, and the detailed analysis methods were reported in our  
174 previous study (Liu et al., 2023).

### 175 **2.2.4. Observation-Based Chemical Box Model**

176 In this work, an observation-based model (OBM) incorporating the latest version 3.3.1  
177 of MCM (MCM v3.3.1; available at <http://mcm.leeds.ac.uk/MCM/>) was utilized to simulate  
178 the acetone photochemical reactions in the chamber. The observation levels of acetone,  
179 acetaldehyde, formic acid and acetic acid, meteorological parameters (temperature and  
180 relative humidity) and the initial  $\text{H}_2\text{O}_2$  concentration were input into the OBM-MCM model  
181 as constraints.

## 182 **3. Results and discussion**

### 183 **3.1. Formation of acetone-derived SOA**

184 Figure 1 shows the time evolution of gas and particle phase species during the reaction  
185 in the presence of  $(\text{NH}_4)_2\text{SO}_4$  seeds. In this study the whole smog chamber reaction process  
186 consists of two phases, of which Phase I is a photochemical reaction of acetone without

187  $\text{NH}_3(\text{g})$  and Phase II is a dark reaction with introduced  $\text{NH}_3$ . During the Phase I, once the  
188 light was turned on the gas phase concentrations of MGly, acetaldehyde, formic acid and  
189 acetic acid quickly increased with a decreasing acetone (Phase I, Figure 1a), while SOA  
190 were instantly produced and sharply increased to over  $90 \mu\text{g m}^{-3}$  (Phase I, Figure 1b). When  
191 the concentration of SOA during the Phase I did not change and even started to decrease, the  
192 light was turned off and  $\text{NH}_3(\text{g})$  was introduced into the chamber (Phase II). According to  
193 the formation time of these gas products, acetaldehyde and MGly are often taken as the first-  
194 generation products, while formic and acetic acids are usually considered as the final-  
195 generation products (Poulain et al., 2010). Oxidation state of compounds (OSc) and O/C  
196 elemental ratio of SOA in the aerosol phase continuously increased during the reaction  
197 process (Figure 1c), which is corresponding to a decreasing fraction of  $\text{CHO}^+$  plus  $\text{C}_2\text{H}_3\text{O}^+$   
198 and an increasing fraction of  $\text{CO}_2^+$  (Figure 1d), indicating an efficient conversion of  
199 carbonyl compounds to carboxylic acid compounds. In the Phase I, we observed an aerosol-  
200 phase decreasing trend of molar ratio of  $\text{NH}_4^+$  to  $\text{SO}_4^{2-}$ , which was accompanied by an  
201 increasing trend of N/C ratio of SOA (Figures 1b and 1c), indicating a transformation of  
202 inorganic  $\text{NH}_4^+$  to N-containing organic compounds. Such a phenomenon can be ascribed to  
203 a reaction of carbonyl compounds with the  $(\text{NH}_4)_2\text{SO}_4$  seeds during the Phase I (Liu et al.,  
204 2023; Li et al., 2021b).

205 As shown in Figures 1a and 1b, after  $\text{NH}_3$  was introduced (Phase II) the formic and  
206 acetic acids decreased dramatically while SOA did not change obviously, suggesting that the  
207 decreases of the gas acids were mainly resulted from the enhanced wall loss due to the  
208 neutralization of  $\text{NH}_3$  on the chamber wall. Interestingly, we found that during the dark  
209 reaction OSc and O/C ratio of SOA decreased slightly but their N/C ratio increased  
210 significantly by a factor of approximately two (Figure 1c), implying that chemical  
211 composition of SOA changed remarkably after  $\text{NH}_3$  was introduced, although the SOA mass  
212 did not change evidently (Figure 1c, Phase II). Moreover, such a slight decrement of O/C  
213 and a significant increment of N/C in the elemental compositions of SOA (Figure 1c) were  
214 also accompanied by a sharp increase of CHN family fragment fractions (Figure 1d, Phase  
215 II), which can be explained by a carbonyl-ammonium condensation under the dark

216 conditions that forms a C-N bond and loses a H<sub>2</sub>O molecule (Aiona et al., 2017; Li et al.,  
217 2021b; Liu et al., 2023). Such an aqueous-phase dark reaction after NH<sub>3</sub> was introduced can  
218 be further revealed by a change in SOA composition during the Phase II, which is  
219 characterized by higher fractions of C<sub>x</sub>H<sub>y</sub>N<sub>1</sub> fragments in the Phase II than those in the  
220 Phase I (Figure 2). Organic ammonium salt would contribute NH<sub>x</sub> fragments instead of  
221 fragments containing N, C, and O elements. Therefore, the CHN species should generated  
222 from the reactions of carbonyls with NH<sub>3</sub> rather than the acid-base neutralization of organic  
223 acid with NH<sub>3</sub> (Liu et al., 2015). As seen in Figure S2, the CHN family species mainly  
224 include CHN, CH<sub>4</sub>N, C<sub>2</sub>H<sub>6</sub>N, C<sub>2</sub>H<sub>7</sub>N, C<sub>2</sub>H<sub>4</sub>N, CH<sub>5</sub>N and C<sub>3</sub>H<sub>6</sub>N ions, which are similar to  
225 the fragments of N-containing organics produced from the reaction of carbonyls with  
226 (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> (De Haan et al., 2010), and increased significantly during the Phase II, resulting  
227 in an enhancing role of NH<sub>3</sub> on the SOA formation from acetone photochemical reaction.

### 228 **3.2. Enhancing effect of seeds on the SOA formation**

229 As shown in Figure S3, the concentration of SOA derived from acetone photochemical  
230 reactions in the presence of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> seeds is twenty times higher than that in the absence  
231 of the seeds, suggesting that the occurrence of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> seeds remarkably promoted the  
232 SOA formation. Such an enhancing role was also found for Na<sub>2</sub>SO<sub>4</sub> and NH<sub>4</sub>HSO<sub>4</sub> seeds  
233 (Figure S4). Because of the significant influence of surface area of aerosols on the  
234 multiphase reactions (Huang et al., 2016), the SOA formation amounts were normalized by  
235 the aerosol surface area (SA) to eliminate the interference of the difference in seed  
236 concentrations. As seen in Figure 3a, the normalized concentration of SOA on Na<sub>2</sub>SO<sub>4</sub> seeds  
237 is two times larger than that on (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> and NH<sub>4</sub>HSO<sub>4</sub> seeds, respectively, indicating that  
238 the difference in physicochemical properties of seeds are of different promoting effects on  
239 the SOA formation. MGly is one of the first-generation oxidation products of the acetone  
240 photochemical reactions and also one of the critical precursor of SOA (Li et al., 2021b).  
241 Therefore, we choose it as the target compound to explore the effect of the seeds on the SOA  
242 formation. The multiphase reactions of acetone-derived MGly in the chamber can be divided  
243 into two processes: the gas-particle partitioning and the subsequent aqueous phase reactions  
244 (Srivastava et al., 2022; Waxman et al., 2015), which are further discussed as follows:

### 245 **3.2.1. The effects on the gas-to-particle phase partitioning**

246 It has been reported that the presence of salts in aerosol aqueous phase can significantly  
247 influence the gas-particle phase partitioning of MGly, which can decrease the solubility of  
248 MGly, i.e., salting out effect (Waxman et al., 2015). In this study, the effective Henry's law  
249 constants ( $K_{H, \text{salt}}$ ) of MGly in the aqueous phase of various seeds were further estimated by  
250 Eq.2 (Waxman et al., 2015; Cui et al., 2021).

$$\log \left( \frac{K_{H,w}}{K_{H,salt}} \right) = K_S c_{salt} \quad (2)$$

251 Where  $K_{H,w}$  and  $K_{H, \text{salt}}$  are the Henry's law constants of MGly in pure water ( $3.71 \times 10^3 \text{ M}$   
252  $\text{atm}^{-1}$ ) (Curry et al., 2018) and in a salt solution, respectively;  $K_S$  is the salting constant or  
253 Setschenow constant, which is  $0.16 \text{ M}^{-1}$  used in this work (Waxman et al., 2015), supposing  
254 that the  $K_S$  values are similar in the three types of inorganic aerosols (Gen et al., 2018);  $c_{\text{salt}}$   
255 is the salt concentration in molality.

256 As shown in Figure 3b,  $K_{H, \text{salt}}$  of MGly on  $\text{Na}_2\text{SO}_4$  seeds in this study is more than two  
257 times that on  $(\text{NH}_4)_2\text{SO}_4$  and  $\text{NH}_4\text{HSO}_4$  seeds, respectively, because of its lower salt  
258 concentration and weaker salting out effect. The acidity of aerosol aqueous phase also can  
259 affect the uptake of MGly. For instance, Zhao et al. (2006) found that the effective Henry's  
260 law constant of MGly decreased with an increase of aqueous acidity in their laboratory  
261 experiments. As shown in Figure 3b, the pH values of  $\text{Na}_2\text{SO}_4$ ,  $(\text{NH}_4)_2\text{SO}_4$  and  $\text{NH}_4\text{HSO}_4$   
262 seeds in our chamber study are 7.0, 4.9 and -0.2, respectively, indicating that the neutral  
263 nature of  $\text{Na}_2\text{SO}_4$  seeds is more favorable for the uptake of MGly compared to the two other  
264 acidic seeds. In addition, the higher OSc and larger fraction of  $\text{C}_x\text{H}_y\text{O}_z$  signals of SOA on  
265  $\text{Na}_2\text{SO}_4$  seeds (Figure 3a and Figure S5) may also be caused by enhanced uptake of  
266 carboxylic acids (e.g., formic and acetic acids) in comparison with those by other two kinds  
267 of acidic seeds (Huang et al., 2016), which also resulted in the less abundant formic and  
268 acetic acids in the gas phase at the end of Phase I during the  $\text{Na}_2\text{SO}_4$  seed experiment  
269 (Figure S6).

### 270 **3.2.2. The effects on the aqueous reaction**

271 The aqueous formation of SOA could be affected by the phase state and acidity of

272 aerosols (Amorim et al., 2020; Amorim et al., 2021; Shen et al., 2022). Since particles in all  
273 the experiments of this work are deliquesced under 85% RH conditions (Wong et al., 2015;  
274 Bateman et al., 2015), the influence of phase state can be neglected. Here, we focus on the  
275 impact of aerosol acidity on the SOA formation pathway by characterizing the chemical  
276 composition of SOA in the chamber using ESI-Q-MS technique. The mass spectra of SOA  
277 formed on different seeds are shown in Figures 3c and 3d, and the detail peak assignments  
278 are presented in Table S2, respectively. As shown by Figures 3c and 3d, the main peaks of  
279 SOA formed on Na<sub>2</sub>SO<sub>4</sub> seeds locate in the mass range lower than m/z=200, whereas the  
280 main peaks of SOA formed on (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> seeds locate in the mass range larger than  
281 m/z=200, clearly showing that SOA formed on neutral aerosols are dominated smaller  
282 molecules while those formed on acidic aerosols are dominated larger molecules. [The  
283 phenomenon can be attributed to the promotion of the acid-catalyzed reactions in the  
284 formation of high-order oligomers on the acidic seeds \(Jang et al., 2002; Zhang et al.,  
285 2015a\)](#). On the other hand, such different formation pathways of SOA also can be explained  
286 by the difference of reactive oxygen species formed in the aqueous phase of the different  
287 aerosols. On neutral aerosols, organic hydroperoxides produced from the reaction of  
288 peroxides radicals and HO<sub>2</sub> radicals decompose and generate OH radicals through the  
289 cleavage of the weaker O-O bond (Wei et al., 2022). Then, the OH radicals oxidize the  
290 oligomers to low molecular weight (LMW) compounds (Zhao et al., 2017). In contrast, on  
291 acidic aerosols the acid-catalyzed thermal decomposition of the organic hydroperoxides  
292 leads to the formation of alcohol and ketone as the end products, which does not involve  
293 radical formation (Wei et al., 2022; Yaremenko et al., 2016). Then, the carbonyls in the  
294 aqueous phase will undergo hydration, oligomerization and acid-catalyzed aldol  
295 condensation to form high molecular weight (HMW) compounds (Zhang et al., 2015a;  
296 Kenseth et al., 2023; Li et al., 2021b). Such an explanation can be supported by the higher  
297 OSc of SOA formed on the neutral aerosols (Figure 3a). On the other hand, the lower SOA  
298 mass formed on acidic aerosols can also in part be attributed to the different reactivity of OH  
299 radical to carboxylic group; OH radical does not react with the carboxyl group (COOH)  
300 rapidly through H-abstraction from an O-H bond, but OH radical is more reactive to the

301 carboxylate group ( $\text{ROO}^-$ ) by abstracting an electron, which can result in a high SOA yield  
302 on neutral aerosols (Amorim et al., 2021; Herrmann et al., 2015).

### 303 **3.3 The different effect of $\text{NH}_3$ on SOA formation on different seeds**

304 As shown in Figure 4a, when  $\text{NH}_3$  was introduced into the reaction system (Phase II),  
305 the ratio of N/C of SOA increased significantly because of the reaction of  $\text{NH}_4^+/\text{NH}_3$  with  
306 carbonyls on acidic  $(\text{NH}_4)_2\text{SO}_4$  and  $\text{NH}_4\text{HSO}_4$  seeds, but such an evident change was not  
307 observed in the presence of  $\text{NH}_3$  for neutral  $\text{Na}_2\text{SO}_4$  seeds. One of the reasons is that  $\text{NH}_3$   
308 dissolve more readily on acidic aerosols. The gas-to-particle phase partition coefficients of  
309  $\text{NH}_3$  ( $\epsilon(\text{NH}_4^+)$ ) on different seeds were calculated (Text S5) (Guo et al., 2017; Lv et al.,  
310 2023). As shown in Figure 4b,  $\epsilon(\text{NH}_4^+)$  is zero and 1.0 for  $\text{Na}_2\text{SO}_4$  and  $\text{NH}_4\text{HSO}_4$  seeds,  
311 respectively, suggesting that  $\text{NH}_3$  was almost not absorbed by  $\text{Na}_2\text{SO}_4$  seeds but efficiently  
312 absorbed by  $\text{NH}_4\text{HSO}_4$  seeds. [The phenomenon can be confirmed by the Figure S7, more N](#)  
313 [mass partitioned on more acidic aerosols.](#) Liu et al. (2015) analyzed the uptake of  $\text{NH}_3$  onto  
314 SOA and also found that the uptake coefficient positively correlated with particle acidity.  
315 Several studies put forward that the reaction of  $\text{NH}_3$  with carbonyl are likely acid-catalyzed  
316 (Zhang et al., 2015a; Liu et al., 2015). However, such a conclusion was inconsistent with the  
317 phenomenon observed by Yang et al. (2024); they found that the light absorption ability of  
318 brown carbon produced from the aqueous reactions of  $\alpha$ -dicarbonyls with ammonium or  
319 amine increased exponentially with the increase of pH. To resolve such a disagreement. We  
320 analyzed the chemical composition of SOA detected by HR-ToF-AMS at different reaction  
321 phases. As shown in Figure S5a-d, no change was observed on  $\text{Na}_2\text{SO}_4$  particles at Phase II  
322 after  $\text{NH}_3$  was introduced, but the fraction of the CHN family species increased dramatically  
323 on  $(\text{NH}_4)_2\text{SO}_4$  and  $\text{NH}_4\text{HSO}_4$  particles at phase II. Hence, we supposed that  $\text{NH}_3$  can  
324 promote the formation of N-containing SOA on acidic aerosols significantly via reacting  
325 with carbonyl compounds. To verify such an assumption, we performed additional  
326 experiments by introducing 500 ppb  $\text{SO}_2$  into the chamber in the presence of  $\text{Na}_2\text{SO}_4$  seeds  
327 after Phase II (Phase III, Figure S8). The addition of  $\text{SO}_2$  resulted in  $(\text{NH}_4)_2\text{SO}_4$  produced  
328 immediately in the chamber (Phase III, Figure S8a), and then the fraction of CHN species  
329 increased sharply (Phase III, Figure S8b). Such results again demonstrate the pivotal role of

330 acidic particles in the formation of N-containing SOA.

331 The optical properties of the acetone-derived SOA on different particles were measured  
332 by LWCC. Compared with the light absorption spectra of SOA formed on Na<sub>2</sub>SO<sub>4</sub> seeds in  
333 the absence of SO<sub>2</sub>, an enhanced MAC peak at ~270 nm was observed for SOA formed on  
334 (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> seeds and on Na<sub>2</sub>SO<sub>4</sub> seeds with SO<sub>2</sub>, respectively (Figure 4c). Such enhanced  
335 absorptions are in agreement with that of the products from MGly and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> reaction,  
336 which displays prominent peaks at <240 and ~270 nm with a tail extending to >350 nm  
337 (Kasthuriarachchi et al., 2020). The increased absorption peak at 270 nm can be ascribed to  
338 a formation of imidazoles through the reaction of MGly with NH<sub>4</sub><sup>+</sup> (You et al., 2020). In this  
339 work, 1H-imidazole-4-carboxylic acid was observed for the SOA formed on (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>  
340 seeds (Figure 4d). However, there was no absorption peak at ~270 nm for the products of the  
341 Na<sub>2</sub>SO<sub>4</sub> particles in the absence of SO<sub>2</sub> (Figure 4c), further confirming the enhancement  
342 effect of acidic particles on the formation of light-absorbing SOA, which is often termed as  
343 brown carbon.

#### 344 **3.4. Formation mechanisms of acetone-derived SOA on different seeds**

345 Figure 5 shows the mass yield and MAC of acetone-derived SOA at the end of Phase II.  
346 Clearly, SOA is formed more readily on neutral Na<sub>2</sub>SO<sub>4</sub> seeds than on acidic (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>  
347 seeds. However, in the presence of NH<sub>3</sub>, SOA formed on (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> seeds are more light-  
348 absorbing than those formed on Na<sub>2</sub>SO<sub>4</sub> aerosols, suggesting that a stronger acidity of  
349 aerosol phase is favorable for the formation of light-absorbing organics, because NH<sub>3</sub> cannot  
350 be taken up by neutral aerosols and thus carbonyl-ammonium condensation is only active  
351 under acidic conditions and produce light-absorbing N-containing organics.

352 By combining the gas and aerosol phase chemistry evolution in the chamber, chemical  
353 mechanism for SOA formation from acetone multiphase photochemical reactions on  
354 different aerosols in the presence of NH<sub>3</sub> was proposed (Figure 6). The photochemical  
355 reactions of acetone in this work include photolysis and oxidation by OH radicals, which  
356 produce various peroxy radical (RO<sub>2</sub>) and undergo two RO<sub>2</sub> fates, RO<sub>2</sub>+HO<sub>2</sub> and RO<sub>2</sub>+RO<sub>2</sub>  
357 reactions. The loss rates of two RO<sub>2</sub> pathways are shown in Figure S10. Obviously,  
358 RO<sub>2</sub>+HO<sub>2</sub> was the main pathway in RO<sub>2</sub> chemistry, the loss rate of which was 3.19 times

359 that of RO<sub>2</sub>+RO<sub>2</sub> pathway. Concentrations of main gaseous products from RO<sub>2</sub> chemistry  
360 are shown in Table S3. C<sub>2</sub>H<sub>4</sub>O<sub>3</sub> and C<sub>3</sub>H<sub>6</sub>O<sub>3</sub> are intermediate volatility organic compounds  
361 (IVOCs) and can undergo gas-particle partitioning readily to form SOA. Moreover, there are  
362 abundant gas-phase intermediate products containing hydrophilic functional groups such as  
363 alcohol, ketone and organic acids formed from acetone photochemical reactions, which can  
364 dissolve into aqueous phase and undergo further oxidation reaction, esterification reaction  
365 and radical-radical reaction to form SOA on particles (Poulain et al., 2010; Ge et al., 2017).  
366 For example, the dissolved MGly can be hydrolyzed and then oxidized into organic acids  
367 such as pyruvic and oxalic acids or proceeds to a series of oligomerizations to produce many  
368 oligomers, giving rise to SOA formation. The acetone alcohol can react with acetic acid to  
369 form esters C<sub>5</sub>H<sub>8</sub>O<sub>3</sub> in aqueous phase. The organic hydroperoxide C<sub>3</sub>H<sub>6</sub>O<sub>3</sub> produced from  
370 acetone-RO<sub>2</sub>+HO<sub>2</sub> pathway also can react with acetic acid and pyruvic acid to form C<sub>5</sub>H<sub>8</sub>O<sub>4</sub>  
371 and C<sub>6</sub>H<sub>8</sub>O<sub>5</sub> in particle phase, respectively. These esterification reactions can also contribute  
372 to SOA formation effectively.

373 In the presence of NH<sub>4</sub><sup>+</sup>, carbonyl compounds in the aerosol phase can react with free  
374 NH<sub>3</sub> molecules and produce N-containing SOA including imine, imidazole and other  
375 oligomers (Liu et al., 2023). LMW SOA are formed readily in neutral aerosol phase, while  
376 HMW SOA and N-containing brown carbon are formed favorably in acidic aerosol phase,  
377 because the acidic condition is favorable for the uptake of NH<sub>3</sub>. The carbenium cations,  
378 which are produced from protonation and dehydration of the hydration products of MGly  
379 under acidic conditions, are the key intermediates for formation and propagation of  
380 oligomerization (Ji et al., 2020). The oligomers and N-heterocycles are produced from the  
381 nucleophilic addition of the negative hydroxyl O-atom of hydration products and the  
382 negative N-atom of NH<sub>3</sub> to the carbenium cations, respectively (Li et al., 2021b; Li et al.,  
383 2021a).

### 384 **3.5. Comparison of SOA from acetone with that from MGly in the chamber**

385 Currently, estimations of acetone-derived SOA by models only consider its product  
386 MGly as the precursor (Fu et al., 2008). The uptake coefficient ( $\gamma$ ) of MGly used in their  
387 work is  $2.9 \times 10^{-3}$  without taking into account the influence of salting effects. Curry et al.

388 (2018) revised the  $\gamma$  to  $10^{-10}$ - $10^{-6}$  after considering salting effects, aerosol thermodynamics,  
 389 mass transfer, and irreversible reactions of organic species with OH in aqueous phase. In  
 390 addition, previous laboratory studies showed a large difference among the uptake  
 391 coefficients of MGly, ranging from  $4.0 \times 10^{-7}$  to  $2.4 \times 10^{-2}$  (Li et al., 2023; Li et al., 2021b).  
 392 Salting effects and other VOCs such as formaldehyde and acetaldehyde also can influence  
 393 the SOA formation from aqueous reaction of MGly (Rodriguez et al., 2017; Waxman et al.,  
 394 2015). These documented values suggest a big uncertainty for SOA model work on MGly.  
 395 Currently, the uptake coefficient ( $\gamma$ ) of MGly is set as  $2.6 \times 10^{-4}$  in CMAQ v5.3 (Chen et al.,  
 396 2021). Hence, the concentration of SOA formed in the chamber only from the irreversible  
 397 uptake of MGly can be calculated by Eq.3 (Chen et al., 2021; Li et al., 2023).

$$\frac{\partial aqSOA}{\partial t} = \left( \frac{a}{D_g} + \frac{4}{v_{MGLY}\gamma_{MGLY}} \right)^{-1} A[MGLY] \quad (3)$$

398 Where  $\frac{\partial aqSOA}{\partial t}$  is the formation rate of SOA in experiments;  $a$  is the effective radius of  
 399 aerosols;  $D_g$  is the gas-phase molecular diffusion coefficient;  $V_{MGLY}$  is the gas-phase mean  
 400 molecular speed of MGly;  $A$  is the aerosol surface area per unit air volume;  $[MGLY]$  is the  
 401 vapor-wall loss corrected concentration of MGly (see the details in Text S3).

402 As shown in Table 1, the concentrations of the total SOA-derived from acetone  
 403 photochemical reaction in the chamber is 2.8-8.2 times that only from the irreversible uptake  
 404 of MGly, suggesting that only considering the role of MGly will inevitably underestimate  
 405 the contribution of acetone to SOA production in the atmosphere especially in polluted  
 406 urban regions, which are often characteristic of high loadings of acetone and aerosols.

#### 407 **4. Conclusions**

408 In this study we investigated the mass yield and formation mechanism of SOA from  
 409 acetone photochemical reaction in the presence of preexisting haze particles ( $(NH_4)_2SO_4$  and  
 410  $NH_4HSO_4$ ) and mineral dusts ( $Na_2SO_4$ ) under ammonia-rich conditions. We found that the  
 411 presence of seeds can significantly promote the formation of acetone-derived SOA, and the  
 412 SOA yield on  $Na_2SO_4$  seeds is larger than that on acidic  $(NH_4)_2SO_4$  and  $NH_4HSO_4$  seeds,  
 413 indicating that the differences in physicochemical properties of pre-existing aerosols are of

414 different promoting effects on the acetone-derived SOA formation. In comparison with those  
415 of  $(\text{NH}_4)_2\text{SO}_4$ , and  $\text{NH}_4\text{HSO}_4$  seeds, the weaker salting-out effect and lower acidity of  
416  $\text{Na}_2\text{SO}_4$  seeds are in favor of the gas-to-particle partitioning of the SOA precursors.  
417 Moreover, SOA formed on the neutral seeds are dominated by smaller molecules with a  
418 higher OSc, while those formed on the acidic seeds are dominated by larger molecules with  
419 a lower OSc.

420 Because  $\text{NH}_3$  cannot be taken up by neutral aerosols, heterogeneous reaction of  
421 carbonyl with ammonium is only active under acidic conditions, which produces light-  
422 absorbing N-containing compounds such as imidazoles, resulting in the acetone-derived  
423 SOA formed on  $(\text{NH}_4)_2\text{SO}_4$  seeds more light absorbing than those formed on  $\text{Na}_2\text{SO}_4$  seeds.  
424 In the chamber the total SOA-derived from acetone photochemical reaction is 2.8-8.2 times  
425 that only from the irreversible uptake of MGly, suggesting that only considering the  
426 irreversible uptake of MGly will inevitably underestimate the contribution of acetone  
427 photochemical reactions to SOA in the atmosphere.

**Table 1.** Concentrations of total SOA formed in the chamber and that formed only from the uptake of methylglyoxal (MGly) in the chamber

Seed	SOA <sup>a</sup> ( $\mu\text{g m}^{-3}$ )	Surface area of seeds ( $\text{m}^2 \text{m}^{-3}$ )	MGly ( $\mu\text{g m}^{-3}$ )	$\gamma^b$	SOA <sub>MGly</sub> <sup>c</sup> ( $\mu\text{g m}^{-3}$ )	SOA/SOA <sub>MGly</sub>
Na <sub>2</sub> SO <sub>4</sub>	140	$9.30 \times 10^{-3}$	26.74	$2.6 \times 10^{-4}$	17.17	8.2
(NH <sub>4</sub> ) <sub>2</sub> SO <sub>4</sub>	101	$1.95 \times 10^{-2}$	42.95	$2.6 \times 10^{-4}$	28.88	3.5
NH <sub>4</sub> HSO <sub>4</sub>	57	$1.14 \times 10^{-2}$	38.43	$2.6 \times 10^{-4}$	20.17	2.8

<sup>a</sup>SOA values are the concentrations of SOA on different seeds observed in the experiments. <sup>b</sup>The values of  $\gamma$  are consistent with the parameters of the irreversible uptake of MGly used in CMAQ v5.3. <sup>c</sup>SOA<sub>MGly</sub> is estimated concentration of SOA formed from the irreversible uptake of MGly on different aerosols.

673

674

## Figure Captions

675 **Figure 1.** Time evolution of gas-phase and aerosol-phase species in the presence of  
676  $(\text{NH}_4)_2\text{SO}_4$  seeds during acetone oxidation process (Phase I: Photochemical reactions of  
677 acetone by OH radicals without  $\text{NH}_3$ ; Phase II: Reaction of acetone oxidation products with  
678  $\text{NH}_3$  under dark conditions) (a) Gas-phase compounds; (b) SOA and molar ratio of  $\text{NH}_4^+$  to  
679  $\text{SO}_4^{2-}$  in the aerosol-phase; (c) N/C and O/C elemental ratios and oxidation state of  
680 compounds (OSc,  $2 \times \text{O/C} - \text{H/C}$ ) of SOA; (d) Relative abundances of  $\text{CO}_2^+$ , the sum of  $\text{CHO}^+$   
681 plus  $\text{C}_2\text{H}_3\text{O}^+$ , and CHN family fragments of SOA.

682

683

684

685 **Figure 2.** Fragment compositions of acetone-derived SOA in the presence of  $(\text{NH}_4)_2\text{SO}_4$   
686 seeds between the two reaction phases. (Phase I: Oxidation of acetone by OH radicals  
687 without  $\text{NH}_3$ ; Phase II: Reaction of acetone oxidation products with  $\text{NH}_3$  under dark  
688 conditions)

689

690

691 **Figure 3.** Effect of seed acidity on SOA formation. (a) The amount SOA normalized by the  
692 surface area (SA) of aerosols and OSc of SOA in the presence of different seeds at Phase I;  
693 (b) Effective Henry's law constants ( $K_{\text{H, salt}}$ ) of MGly and acidity (pH) of inorganic aerosols  
694 during the reaction; (c) and (d) Mass spectra of SOA from acetone oxidations by OH  
695 radicals with no  $\text{NH}_3$  in the presence of  $\text{Na}_2\text{SO}_4$  and  $(\text{NH}_4)_2\text{SO}_4$  seeds, respectively.

696

697

698 **Figure 4.** Effect of ammonia on SOA formation. (a) The Difference in N/C ratio of Phase II  
699 relative to Phase I on different seeds; (b) Partitioning coefficients of  $\text{NH}_3$  ( $\epsilon(\text{NH}_4^+)$ ) on  
700 different seeds in the chamber; (c) MAC of acetone-derived SOA in the presence of different  
701 seeds; (d) Mass spectrum of 1H-imidazole-4-carboxylic acid formed during the  
702 heterogeneous oxidation of acetone in the presence of  $(\text{NH}_4)_2\text{SO}_4$  seed.

703

704

705 **Figure 5.** SOA yield (green) and  $\text{MAC}_{\lambda=270 \text{ nm}}$  (red) of acetone-derived SOA in the presence  
706 of  $\text{Na}_2\text{SO}_4$  and  $(\text{NH}_4)_2\text{SO}_4$  seeds with  $\text{NH}_3$  under dark conditions (Phase II), respectively.

711

712 **Figure 1.** Time evolution of gas-phase and aerosol-phase species in the presence of  
 713 (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> seeds during acetone oxidation process (Phase I: Photochemical reactions of  
 714 acetone by OH radicals without NH<sub>3</sub>; Phase II: Reaction of acetone oxidation products with  
 715 NH<sub>3</sub> under dark conditions) (a) Gas-phase compounds; (b) SOA and molar ratio of NH<sub>4</sub><sup>+</sup> to  
 716 SO<sub>4</sub><sup>2-</sup> in the aerosol-phase; (c) N/C and O/C elemental ratios and oxidation state of  
 717 compounds (OSc, 2×O/C-H/C) of SOA; (d) Relative abundances of CO<sub>2</sub><sup>+</sup>, the sum of CHO<sup>+</sup>  
 718 plus C<sub>2</sub>H<sub>3</sub>O<sup>+</sup>, and CHN family fragments of SOA.

**Figure 3.** Effect of seed acidity on SOA formation. (a) The amount SOA normalized by the surface area (SA) of aerosols and OSc of SOA in the presence of different seeds at Phase I; (b) Effective Henry's law constants (K<sub>H, salt</sub>) of MGly and acidity (pH) of inorganic aerosols during the reaction; (c) and (d) Mass spectra of SOA from acetone oxidations by OH radicals with no NH<sub>3</sub> in the presence of Na<sub>2</sub>SO<sub>4</sub> and (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> seeds, respectively.

739

740 **Figure 4.** Effect of ammonia on SOA formation. (a) The Difference in N/C ratio of Phase II  
 741 relative to Phase I on different seeds; (b) Partitioning coefficients of NH<sub>3</sub> ( $\epsilon(\text{NH}_4^+)$ ) on  
 742 different seeds in the chamber; (c) MAC of acetone-derived SOA in the presence of different  
 743 seeds; (d) Mass spectrum of 1H-imidazole-4-carboxylic acid formed during the  
 744 heterogeneous oxidation of acetone in the presence of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> seed.
