6 **1 Analytical equality of $\eta(t)$ and direct atmosphere removal**

7 Consider a simple box model comprising an atmosphere box of finite volume, and an ocean mixed
8 layer box, as shown in Figure S1. The intent is not to create a model with detailed realism but to
9 demonstrate the consequences of modelling the atmosphere to be finite, and therefore change its
10 pCO_2 in response to fluxes of CO_2 across the air-sea interface.

11 Firstly, the flux of CO_2 across the air-water interface is typically modelled as proportional to
12 the partial pressure difference

$$F_{CO_2} = k_w \alpha (pCO_2^{atm} - pCO_2^{ocn}) = k_w \alpha \Delta pCO_2, \quad (1)$$

13 where α is the solubility of CO_2 in seawater [$\approx 34 \text{ mol/m}^3/\text{atm}$] and k_w is the gas transfer
14 velocity [m/s]. Thus, the total amount of dissolved inorganic carbon (DIC) in the mixed layer and
15 the atmosphere respectively change according to

$$\frac{dC^{ocn}}{dt} = -\frac{dC^{atm}}{dt} = F_{CO_2} A = k_w \alpha A \Delta pCO_2 = \Psi \Delta pCO_2 \quad (2)$$

16 where A is the surface area over which gas exchange occurs. For later convenience, Ψ is defined
17 here as $k_w \alpha A$. The atmospheric partial pressure pCO_2^{atm} is directly proportional to the total
18 amount of CO_2 in the atmosphere C^{atm} in [mol]

$$pCO_2^{atm} = V_m p \frac{C^{atm}}{V_{atm}}, \quad (3)$$

19 where V_m is the molar volume of gas ($0.024 \text{ m}^3/\text{mol}$) and p is the atmospheric pressure. Or as
20 a differential:

$$\frac{dpCO_2^{atm}}{dC^{atm}} = \frac{V_m p}{V_{atm}} \quad (4)$$

21 In the ocean (specifically in the mixed layer, "ml") the differential relationship between pCO_2
22 and C , for small changes in either, is

$$\frac{dpCO_2^{ocn}}{dC^{ocn}} = \frac{1}{\alpha V_{ml}} \frac{\partial[CO_2]}{\partial[DIC]} \quad (5)$$

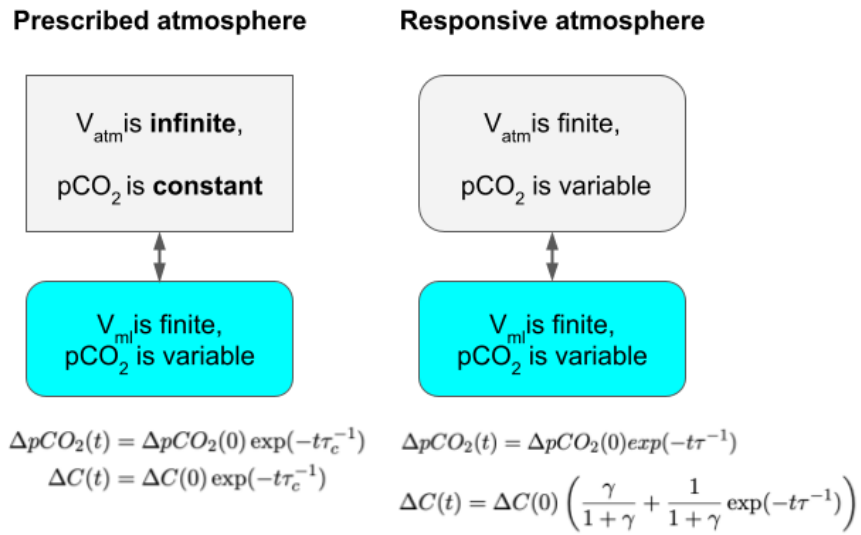

Figure S1: Two simple box models, one with a static, prescribed atmosphere and one with a reactive finite-volume atmosphere. The resulting decay laws for an initial pulse of CO_2 added to to ocean ($\Delta C(0)$) and and initial pulse of $p\text{CO}_2(0)$ are given below.

23 where $[DIC]$ is the concentration of total dissolved carbon and α is the solubility of CO_2 in
 24 seawater (Zeebe and Wolf-Gladrow, 2001). This relation follows from the following differential
 25 relationships $d[DIC] = dC/V_{ml}$ and $dpCO_2 = \frac{1}{\alpha}d[CO_2]$.

26 Now the changes in partial pressure in the atmosphere and ocean mixed layer can be written
 27 using the chain rule ($\frac{dpCO_2}{dt} = \frac{dC}{dt} \cdot \frac{dpCO_2}{dC}$) as:

$$\frac{dpCO_2^{atm}}{dt} = -\Psi \Delta pCO_2 \frac{dpCO_2^{atm}}{dC^{atm}} \quad (6)$$

$$\frac{dpCO_2^{oce}}{dt} = \Psi \Delta pCO_2 \frac{dpCO_2^{ocn}}{dC^{ocn}} \quad (7)$$

28 The partial pressure difference between the two reservoirs thus evolves as

$$\frac{d\Delta pCO_2}{dt} = \frac{dpCO_2^{atm}}{dt} - \frac{dpCO_2^{oce}}{dt} = -\Psi \left[\frac{dpCO_2^{atm}}{dC^{atm}} + \frac{dpCO_2^{ocn}}{dC^{ocn}} \right] \Delta pCO_2 \quad (8)$$

$$= -\tau^{-1} \Delta pCO_2 \quad (9)$$

29 This ODE in ΔpCO_2 is readily solved - any partial pressure differences evolve in an exponential
 30 fashion

$$\Delta pCO_2(t) = \Delta pCO_2(0) \exp(-t\tau^{-1}) \quad (10)$$

31 with a characteristic timescale

$$\tau = \Psi^{-1} \left(\frac{dpCO_2^{atm}}{dC^{atm}} + \frac{dpCO_2^{ocn}}{dC^{ocn}} \right)^{-1} \quad (11)$$

32 Note that the frequently taken assumption that atmospheric pCO_2 is constant, corresponds to
 33 the assumption that $V_{atm} = \infty$, in which case $\frac{dpCO_2^{atm}}{dC^{atm}} = 0$, i.e. it assumes an atmosphere which
 34 can accommodate arbitrary movement of CO_2 in or out of it, without a change in pCO_2^{atm} . In this
 35 case the e-folding time simplifies to

$$\tau_c = \Psi^{-1} \left(\frac{dpCO_2^{ocn}}{dC^{ocn}} \right)^{-1} \quad (12)$$

36 denoted here as τ_c for "constant". It is worth noting that the timescale obtained under constant
 37 atmosphere assumptions τ_c is always a little larger than τ due to the missing $\frac{dpCO_2^{atm}}{dC^{atm}}$ term. The
 38 ODE for the pCO_2 difference simplifies to the often used gas-exchange expression (Zeebe and Wolf-
 39 Gladrow, 2001) after substitution of Ψ and $\frac{dpCO_2^{ocn}}{dC^{ocn}}$:

$$\frac{d\Delta pCO_2}{dt} = -\frac{k_w}{z_{ml}} \frac{\partial[CO_2]}{\partial[DIC]} \Delta pCO_2 = -\tau_c^{-1} \Delta pCO_2 \quad (13)$$

40 where the depth of the mixed layer $z_{ml} = V_{ml}/A$.

41 1.1 Differences between reference and perturbed simulations

42 In general, the state of the mixed layer will not be in equilibrium with the atmosphere. Some areas
 43 may be taking in CO_2 , some may be outgassing. The $p\text{CO}_2^{\text{atm}}$ may be changing. However the effects
 44 of a small perturbation can be studied by taking the difference between a reference simulation and
 45 an otherwise identical simulation that has a perturbation applied to it.

46 Since the ODEs describing changes in $\Delta p\text{CO}_2$ in both simulations (let's say A and B) are linear,
 47 the same kinetics also describe any differences between two simulations, say, $\Delta p\text{CO}_2^A$ and $\Delta p\text{CO}_2^B$:

$$\frac{d}{dt}(\Delta p\text{CO}_2^A - \Delta p\text{CO}_2^B) = \frac{d\Delta p\text{CO}_2^A}{dt} - \frac{d\Delta p\text{CO}_2^B}{dt} = -\tau^{-1}(\Delta p\text{CO}_2^A - \Delta p\text{CO}_2^B) \quad (14)$$

48 Therefore, from here on I assume that $\Delta p\text{CO}_2$ and ΔC refer to the difference between a per-
 49 turbed simulation and a reference simulation, for example:

$$\Delta p\text{CO}_2 = (\Delta p\text{CO}_2^A - \Delta p\text{CO}_2^B) = (\Delta p\text{CO}_2^{\text{atm},A} - \Delta p\text{CO}_2^{\text{ml},A}) - (\Delta p\text{CO}_2^{\text{atm},B} - \Delta p\text{CO}_2^{\text{ml},B}) \quad (15)$$

50 1.2 Equilibration of CO_2 inventories under reactive atmospheres

51 How does a small CO_2 deficit of size $\Delta C(0)$ induced in the ocean reservoir evolve in time under
 52 finite, responsive atmospheres? If the perturbation is small then an initial perturbation $\Delta C(0)$
 53 causes a initial change in $p\text{CO}_2^{\text{ocn}}$ of

$$\Delta p\text{CO}_2^{\text{ocn}}(0) = \frac{dp\text{CO}_2^{\text{ocn}}}{dC^{\text{ocn}}} \Delta C(0) \quad (16)$$

54 This initial partial pressure difference will then cause transfer of CO_2 from the atmosphere to
 55 the ocean. The $\Delta p\text{CO}_2$ will equilibrate with the exponential law given by equation 10. The total
 56 rate of transfer of CO_2 between the atmosphere and the ocean (Equation 2) is proportional to
 57 $\Delta p\text{CO}_2$, given by Equation 10:

$$\begin{aligned} \frac{dC}{dt} &= \Psi \Delta p\text{CO}_2(t) \\ &= \Psi \Delta p\text{CO}_2^{\text{ocn}}(0) \exp(-t\tau^{-1}) \\ &= \Delta C(0) \Psi \frac{dp\text{CO}_2^{\text{ocn}}}{dC^{\text{ocn}}} \exp(-t\tau^{-1}) \end{aligned} \quad (17)$$

58 The cumulative transfer of CO_2 is then expressed by the integral of the above rate. Subtract-
 59 ing this integral from the initial perturbation $\Delta C(0)$, the time evolution of the ocean inventory
 60 perturbation in the ocean is obtained:

$$\Delta C(t) = \Delta C(0) - \int_0^t \frac{dC}{dt} dt \quad (18)$$

61 Evaluating the integral

$$\begin{aligned} \Delta C(t) &= \Delta C(0) - \Delta C(0) \Psi \frac{dp\text{CO}_2^{\text{ocn}}}{dC^{\text{ocn}}} \tau [1 - \exp(-t\tau^{-1})] \\ &= \Delta C(0) - \Delta C(0) \frac{\frac{dp\text{CO}_2^{\text{ocn}}}{dC^{\text{ocn}}}}{\frac{dp\text{CO}_2^{\text{atm}}}{dC^{\text{atm}}} + \frac{dp\text{CO}_2^{\text{ocn}}}{dC^{\text{ocn}}}} [1 - \exp(-t\tau^{-1})] \end{aligned} \quad (19)$$

62 where Ψ conveniently cancels. Simplifying yields:

$$\Delta C(t) = \Delta C(0) \left(\frac{\gamma}{1+\gamma} + \frac{1}{1+\gamma} \exp(-t\tau^{-1}) \right) \quad (20)$$

63 where γ expresses the ratio of the capacities of the two interacting reservoirs.

$$\gamma = \frac{dpCO_2^{atm}}{dC^{atm}} \bigg/ \frac{dpCO_2^{ocn}}{dC^{ocn}} = \frac{V_m p \alpha V_{ml}}{V_{atm}} \frac{\partial[DIC]}{\partial[CO_2]} \quad (21)$$

64 As expected, under finite, responsive atmosphere conditions, some fraction of the initial pulse
 65 will always remain in the reservoir it was induced in, even once the pCO_2 values have reached
 66 equilibrium. The fraction that will move to the other reservoir is $\frac{1}{1+\gamma}$, while the fraction that will
 67 remain in the ocean is $\frac{\gamma}{1+\gamma}$.

68 1.3 Equilibration of CO_2 inventories under prescribed atmospheres

69 The non-reactive atmosphere conditions, where the atmosphere is modelled with a constant or
 70 prescribed pCO_2^{atm} , correspond to the assumption that $V_{atm} = \infty$. In that case, $\gamma \rightarrow 0$ and
 71 $(1 + \gamma)^{-1} \rightarrow 1$. Under these circumstances, the evolution of a $\Delta C(0)$ pulse is a simple exponential
 72 decay with the simpler e-folding time τ_c given by Equation ?? and that will decay all the way to
 73 zero.

$$\begin{aligned} \Delta pCO_2(t) &= \Delta pCO_2(0) \exp(-t\tau_c^{-1}) \\ \Delta C(t) &= \Delta C(0) \exp(-t\tau_c^{-1}) \\ \frac{\Delta dC(t)}{dt} &= -\Delta C(0)\tau_c^{-1} \exp(-t\tau_c^{-1}) \end{aligned} \quad (22)$$

74 This is basis of the $\eta(t)$ curve obtained in OAE efficiency simulations(Tyka et al., 2022; He and
 75 Tyka, 2023; Zhou et al., 2024; Suselj et al., 2024).

$$\eta(t) = 1 - \frac{\Delta C(t)}{\Delta C(0)} = 1 - \exp(-t\tau_c^{-1}) \quad (23)$$

76 1.4 Equivalence

77 We have seen that the function $\eta(t)$, determined under constant pCO_2^{atm} conditions, does not
 78 properly describe the actual movement of CO_2 from the atmosphere into the ocean under realistic
 79 conditions (where feedback of the atmosphere is taken into account). This raises the question, what
 80 does $\eta(t)$ represent, if anything? To illuminate this question, consider the following scenario. How
 81 would the total inventory of CO_2 in the atmosphere evolve, under realistic reactive-atmosphere
 82 conditions, if CO_2 was directly removed from the atmosphere at a rate proportional to $d\eta(t)/dt$,
 83 using a terrestrial technology like DAC, instead of indirectly by applying an alkalinity pulse to the
 84 ocean?

85 Specifically, the rate of carbon removal out of the atmosphere would be

$$\frac{d\Delta C}{dt} = \Delta C(0) \frac{d\eta(t)}{dt} = \Delta C(0)\tau_c^{-1} \exp(-t\tau_c^{-1}) \quad (24)$$

86 where $\Delta C(0)$ is a scaling factor that sets the total, eventual amount of CO_2 removed. This
 87 steady removal of CO_2 from the atmosphere lowers the pCO_2 of the atmosphere at a rate of

$$\frac{dpCO_2^{atm}}{dt} = \frac{dpCO_2^{atm}}{dC} \Delta C(0) \tau_c^{-1} \exp(-t\tau_c^{-1}) \quad (25)$$

88 Since the atmosphere now develops a ΔpCO_2 deficit, relative to the ocean, the ocean would
 89 react and degas into to the atmosphere (remember all Δ s are differences between a reference and
 90 a perturbed simulation). The rate of ΔpCO_2 change therefore would be given by the regular gas
 91 exchange ODE (Equation 9) which describes the ongoing ocean-atmosphere equilibration plus the
 92 bias induced by the CO_2 removal process (Equation 25).

$$\frac{d\Delta pCO_2}{dt} = -\tau^{-1} \Delta pCO_2 + \frac{dpCO_2^{atm}}{dC} \Delta C(0) \tau_c^{-1} \exp(-t\tau_c^{-1}) \quad (26)$$

93 This ODE is of the form $y'(t) = gy(t) - mh \exp(th)$ with the solution $y(t) = c_1 \exp(gt) +$
 94 $\frac{hm}{g-h} \exp(ht)$. The initial condition for this linear ODE is $\Delta pCO_2(0) = 0$ since at the moment the
 95 removal starts, the reference and perturbed states are equal. This implies in the generalized form
 96 above $y(t) = 0$ and therefore the constant $c_1 = -\frac{hm}{g-h}$. Hence $y(t) = -\frac{hm}{g-h} \exp(gt) + \frac{hm}{g-h} \exp(ht) =$
 97 $\frac{hm}{g-h} (\exp(ht) - \exp(gt))$

98 Substituting the placeholders g , h and m :

$$\begin{aligned} \Delta pCO_2^{atm}(t) &= \Delta C(0) \left(\frac{dpCO_2^{atm}}{dC^{atm}} \right) \frac{\tau_c^{-1}}{\tau^{-1} - \tau_c^{-1}} [\exp(-t\tau_c^{-1}) - \exp(-t\tau^{-1})] \\ &= \Delta C(0) \frac{\tau_c^{-1}}{\Psi} [\exp(-t\tau_c^{-1}) - \exp(-t\tau^{-1})] \end{aligned} \quad (27)$$

99 Given this trajectory of ΔpCO_2 , what is the combined effect on total atmospheric CO_2 inventory,
 100 i.e. the sum of direct removal and ocean reactance ? The total rate of change is the sum of the
 101 the direct CO_2 removal rate (Equation 24) and the rate due to gas exchange between ocean and
 102 atmosphere (due to the imbalance of ΔpCO_2):

$$\frac{d\Delta C^{atm}}{dt} = \Delta C(0) \tau_c^{-1} \exp(-t\tau_c^{-1}) - \Psi \Delta pCO_2(t) \quad (28)$$

103 Substituting the expression for $\Delta pCO_2^{atm}(t)$ from Equation 27:

$$\begin{aligned} \frac{d\Delta C^{atm}}{dt} &= \Delta C(0) \tau_c^{-1} \exp(-t\tau_c^{-1}) - \Delta C(0) \tau_c^{-1} [\exp(-t\tau_c^{-1}) - \exp(-t\tau^{-1})] \\ &= \Delta C(0) \tau_c^{-1} \exp(-t\tau^{-1}) \\ &= \Delta C(0) \Psi \frac{dpCO_2^{ocn}}{dC^{ocn}} \exp(-t\tau^{-1}) \end{aligned} \quad (29)$$

104 This net rate of change in atmospheric carbon inventory equals precisely that obtained earlier
 105 when considering a a pulsed DIC deficit in the ocean, Equation (17). This result clarifies the exact
 106 meaning of the $\eta(t)$ OAE efficiency curve: The OAE curve of an *instantaneously* induced ocean-
 107 based DIC deficit (obtained under artificial, non-reactive conditions), gives the progression of the
 108 equivalent *gradual* removal of CO_2 directly from the atmosphere (under real, responsive atmosphere
 109 conditions), which would result in the same reduction in net atmospheric carbon inventory.

110 1.5 Calculating $\eta(t)$ from a coupled simulation

111 When simulating OAE under responsive atmospheres or earth system models, it is still useful
 112 to calculate $\eta(t)$, especially for purposes of comparing different negative emissions technologies
 113 and calculating negative emission credits. The directly measured change in the ocean inventory
 114 unfortunately conflates the effect of the OAE intervention and the subsequent feedback. Therefore
 115 a correction is necessary which can be used to factor out the effect of reservoir feedback. Schwinger
 116 et al. (2024) proposed a simple simulation setup to calculate this correction, which allows the
 117 conversion between the two carbon flows under the two different simulation conditions: First one
 118 simulates the fully coupled system with the OAE intervention. Then one conducts an additional
 119 reference simulation in which the atmosphere pCO_2 is prescribed at the exact trajectory obtained in
 120 the fully-coupled simulation with the OAE intervention. However, in the new reference simulation
 121 no OAE is performed - only the atmospheric pCO_2 is prescribed.

122 We can show below, using the the two-box model, that the difference in ocean inventory between
 123 these two simulations indeed equals the $\eta(t)$ value, had the OAE been simulated under prescribed
 124 atmosphere in the first place.

125 The rate of CO_2 transfer due to an OAE pulse under responsive atmosphere is Equation 17

$$\frac{dC^{ocn}}{dt} = \Delta C(0)\Psi \frac{dpCO_2^{ocn}}{dC^{ocn}} \exp(-t\tau^{-1}), \quad (30)$$

126 where $\Delta C(0)$ gives the initial DIC deficit. But under prescribed conditions the rate is given by
 127 Equation 22

$$\frac{d\Delta C^{ocn}}{dt} = -\Delta C(0)\tau_c^{-1} \exp(-t\tau_c^{-1}) \quad (31)$$

128 The correction required is equal to the difference of the two rates, i.e. the purely reactionary
 129 part of the carbon flux caused by the atmosphere feedback equals:

$$\frac{dC^{Feedback}}{dt} = \Delta C(0)\Psi \frac{dpCO_2^{ocn}}{dC^{ocn}} [\exp(-t\tau^{-1}) - \exp(-t\tau_c^{-1})] \quad (32)$$

130 Now consider the reference simulation with the pCO_2 prescribed at the trajectory from the
 131 OAE-perturbed coupled-simulation. In this new reference simulation, the difference in atmospheric
 132 pCO_2 compared to what it would have been without the prescription is equal to the change in
 133 pCO_2 caused by OAE in the fully-coupled simulation. That change is equal to the rate of CO_2
 134 transfer caused by OAE (from Equation 20) times $dpCO_2^{atm}/dC^{atm}$, i.e.

$$\frac{d\Delta pCO_2^{atm}}{dt} = -\frac{dpCO_2^{atm}}{dC^{atm}} \frac{dC^{ocn}}{dt} = \Delta C(0)\Psi \frac{dpCO_2^{atm}}{dC^{atm}} \frac{dpCO_2^{ocn}}{dC^{ocn}} \exp(-t\tau^{-1}) \quad (33)$$

135 In this new reference simulation there will be offgassing of CO_2 from the ocean to the atmosphere
 136 (relative to a completely unperturbed simulation), because the prescribed atmospheric pCO_2 is
 137 lower than it would have been otherwise. The total air-sea difference ΔpCO_2 will then evolve
 138 according to the difference between rates of change of the atmosphere and the ocean:

$$\frac{d\Delta pCO_2}{dt} = -\tau_c^{-1}\Delta pCO_2 - \Delta C(0)\Psi \frac{dpCO_2^{atm}}{dC^{atm}} \frac{dpCO_2^{ocn}}{dC^{ocn}} \exp(-t\tau^{-1}) \quad (34)$$

139 Where the first term is the regular ocean gas-exchange law under prescribed conditions (Equation
 140 13) and the second term is the additional atmospheric pCO_2 deviation due to the prescribed pCO_2

141 trajectory (Equation 33). This, once again, is a linear ODE of the form $y'(t) = gy(t) - m \exp(th)$
 142 with the solution $y(t) = c_1 \exp(gt) + \frac{m}{g-h} \exp(ht)$. Again, the initial condition for this linear ODE is
 143 $\Delta pCO_2(0) = 0$ since up to the point where the atmospheric pCO_2 is prescribed, the new reference
 144 state is identical to the original one.

145 The solution is (after simplification):

$$\Delta pCO_2(t) = \Delta C(0) \frac{dpCO_2^{ocn}}{dC^{ocn}} [\exp(-t\tau^{-1}) - \exp(-t\tau_c^{-1})] \quad (35)$$

146 Which describes the time evolution of the pCO_2 difference across the air-sea interface in this
 147 new reference simulation. The rate of CO_2 transfer caused by this $\Delta pCO_2(t)$ is then obtained from
 148 the gas transfer law (Equation 2), i.e.

$$\frac{dC^{ocn}}{dt} = \Delta C(0) \Psi \frac{dpCO_2^{ocn}}{dC^{ocn}} [\exp(-t\tau^{-1}) - \exp(-t\tau_c^{-1})] \quad (36)$$

149 This matches exactly the sought after $\frac{dC^{Feedback}}{dt}$, given by Equation 32. In other words, as
 150 suggested by Schwinger et al. (2024), the difference in CO_2 ocean inventory between a simulation
 151 with OAE under a responsive atmosphere and one where the pCO_2^{atm} trajectory is prescribed to
 152 that of the former simulation but with no OAE applied yields the same metric (after normalization
 153 by ΔAlk) as given by $\eta(t)$.

154 1.6 Supplementary figures

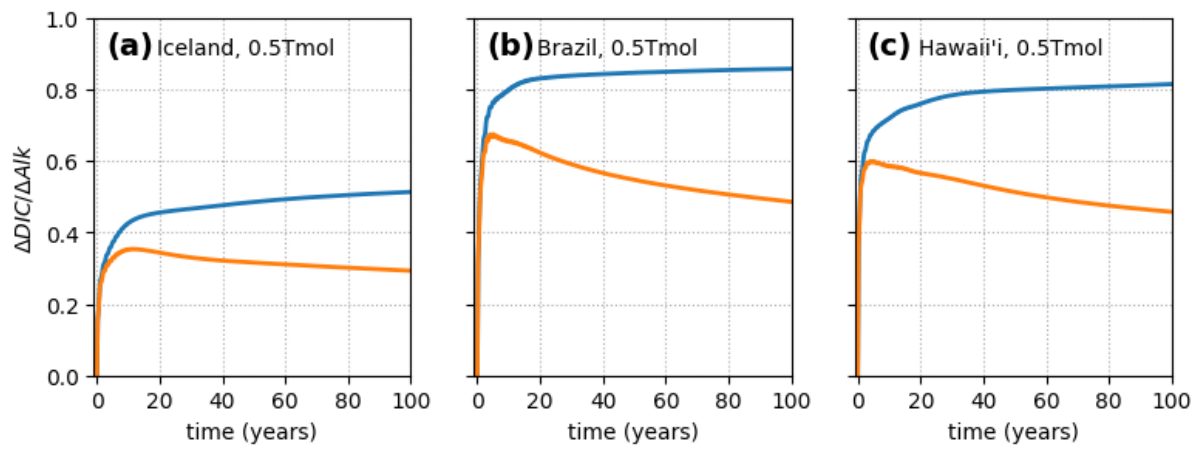

Figure S2: Increase in total ocean DIC following a 1-month pulse of alkalinity (ΔAlk) applied to the surface layer at a specific location, under a prescribed (non-reactive) atmosphere (blue) and a coupled (reactive) atmosphere respectively. The three different point-injection locations were off the coast of Brazil (2.50S,37.50W), near Iceland (61.50N,19.50W) and at Hawaii'i (19.02N,155.49E).
