19 **Text S1**

20 A portion of each quartz filter (10*3.14 cm²) was cut off for analysis. The piece
21 was cut into small pieces and placed into a 30 ml brown vial. 5 mL methanol (Optima
22 LC/MS grade, Fisher Chemical, USA) was added to the brown vial and sonicated for
23 30 minutes at ambient temperature, and the procedure was repeated three times. The
24 solution was then filtrated through a 0.22 μm PTFE filter (Fisher Chemical, USA),
25 followed by the blow-drying with nitrogen gas. The blow-dried solid residue was re-
26 dissolved in 300 μL of methanol and transferred to a 1.5 ml brown injection vial for
27 storage. A 30 μL aliquot from each sample was mixed together as a QC (quality check)
28 sample.

29

30 **Text S2**

31 The analysis was performed by using an Acquity H Class Ultra Performance
32 Liquid Chromatography system coupled to a Xevo G2-Xs Quadrupole time-of-flight
33 mass spectrometer (UPLC-QTOF-MS, Agilent Technologies Inc. Santa Clara, CA,
34 USA). A C18 column (100 mm × 2.1 mm × 1.6 μm) (Luna Omega, Phenomenex) was
35 used for the chromatographic separation, and temperature of the column was
36 maintained at 40 °C. The sample volume was 1.5 μL for the positive ion (ESI⁺) mode
37 and 3 μL for the negative ion (ESI⁻) mode. The mobile phase was consisted of solvent
38 A (ultrapure water containing 0.1% v/v formic acid and 5 mM ammonium acetate) and
39 solvent B (acetonitrile containing 0.1% v/v formic acid), and the gradients of eluent
40 were programmed as follows: 2 % B at 0 ~ 1.5 min; linearly from 2 % B to 20 % B at
41 1.5 ~ 11 min; linearly from 20 % B to 60 % B at 11 ~ 18 min; linearly from 60 % B to
42 98 % B at 18 ~ 20 min; maintain at 98 % B at 20 ~ 22min, then decrease to 2 % B at
43 22 ~ 25 min.

44 The instrument used the electrospray ionization (ESI) technique. A data
45 independent acquisition (DIA) resolution mode was operated with a *m/z* ratio of 50-
46 1200, a scanning interval of 0.1 s, capillary voltages of 0.7 KV for ESI⁺ and 2.35 KV
47 for ESI⁻, a cone bore voltage of 30 V, an ion source temperature of 120 °C, a cone bore

48 gas of 50 L min⁻¹, a desolvation gas of 1000 L min⁻¹, and collision energies of 10 ~ 50
49 eV. The positive or negative ion modes were calibrated with leucine enkephalin and
50 sodium formate polymers, respectively, and data were acquired by using Masslynx 4.1.

51

52 **Text S3**

53 The raw UPLC-QTOF-MS data were processed using the Mass Spectrometry-
54 Data Independent Analysis (MS-DIAL, version 4.92) software, involving peak
55 extraction, peak alignment, and deconvolution with a detection probability of 70 %.
56 The summed ions included [M-H]⁻ (ESI⁻) and [M+H]⁺, [M+NH₄]⁺, [M+Na]⁺ (ESI⁺).
57 Missing data were replaced by 1/10 of the minimum value (default value: 100).
58 Chromatographic intensities were normalized using the systematic error removal using
59 random forest (a machine learning algorithm) (SERRF) software, which is based on the
60 machine learning (ML) random forest (RF) algorithm. Additionally, corrections were
61 applied for potential intensity drift.

62 By using MS-DIAL, all deconvoluted MS/MS spectra were exported as
63 individual .mat files. Subsequently, all MS/MS spectra were examined and imported
64 into SIRIUS (version 5.6.2) for the identification of molecular formulas of each *m/z*. In
65 order to obtain a more refined list of molecular formulas, specific constraints below
66 were applied, and those did not comply with these rules were excluded.

67 (1) Atomic numbers: 1~50 12C, 1 ~ 100 1H, 0 ~ 40 16O, 0 ~ 5 14N, 0 ~ 2 32S;

68 (2) Elemental ratios: In ESI⁻ mode, 0.3 ~ 3.0 H/C, 0 ~ 3 O/C, 0 ~ 0.5 N/C, 0 ~ 2.0
69 S/C; in ESI⁺ mode, 0.3 ~ 3.0 H/C, 0 ~ 1.2 O/C, 0 ~ 1.0 N/C, 0 ~ 0.8 S/C.

70 (3) Equivalent double bond (DBE) numbers: 0 ~ 25.

71 The double-bond equivalent (DBE) value of a molecule is used to indicate the
72 level of unsaturation, which can be calculated by using the following Eq. (S1):

$$73 \quad DBE = \frac{2 \times C - H + N + 2}{2} \quad (S1)$$

74 Here, C, H, N are the number of carbon, hydrogen and nitrogen in the formula of
75 the molecule. Furthermore, the aromaticity equivalent (Xc) has been used to aid the
76 identification of aromatic and condensed aromatic compounds, as described in Yassine

77 et al. (2014). Compared to the aromaticity index (AI), the advantage of X_c lies in its
 78 ability to accurately classify (poly)aromatic compounds with significant alkylations.
 79 The X_c value can be calculated with Eq. (S2):

$$80 \quad X_c = \frac{3 \times (DBE - (p \times O + q \times S)) - 2}{DBE - (p \times O + q \times S)} \quad (S2)$$

81 Where p and q are the fractions of oxygen and sulfur atoms involved in the π -
 82 bond structure of the molecule, respectively. In this study, $p = q = 0.5$ was used for the
 83 compounds detected in ESI⁻, and $p = q = 1$ was selected for ESI⁺ (Kourtchev et al., 2016;
 84 Tong et al., 2016) because ESI⁻ is more sensitive to compounds containing carboxylic
 85 groups, and compounds with a large diversity of functional groups can possibly be
 86 detected in ESI⁺. Compounds with $X_c < 2.5$ were considered to be non-aromatics, with
 87 $X_c \geq 2.5$ indicating aromatics and $X_c \geq 2.71$ being considered as condensed aromatics
 88 (Yassine et al., 2014).

89 The O/C, H/C and DBE of a sample was calculated over all identified molecules
 90 based on their relative abundances, as follows:

$$91 \quad O/C = \frac{\sum (I_{in_i} * O/C_i)}{\sum I_{in_i}} \quad (S3)$$

$$92 \quad H/C = \frac{\sum (I_{in_i} * H/C_i)}{\sum I_{in_i}} \quad (S4)$$

$$93 \quad DBE = \frac{\sum (I_{in_i} * DBE_i)}{\sum I_{in_i}} \quad (S5)$$

94 Where I_{in_i} represents the relative abundance of molecule i , O/C_i , H/C_i and DBE_i ,
 95 represent the O/C, H/C and DBE of the molecule i , respectively.

96 Table S1. Numbers of molecules, number fractions of different types of identified
 97 compounds to the total, and their average O/C, H/C and DBE values.

| | Ion mode | Molecular types | Number of molecules | Number fractions | O/C | H/C | DBE |
|--------------------|------------------|-----------------|---------------------|------------------|------|---------|------|

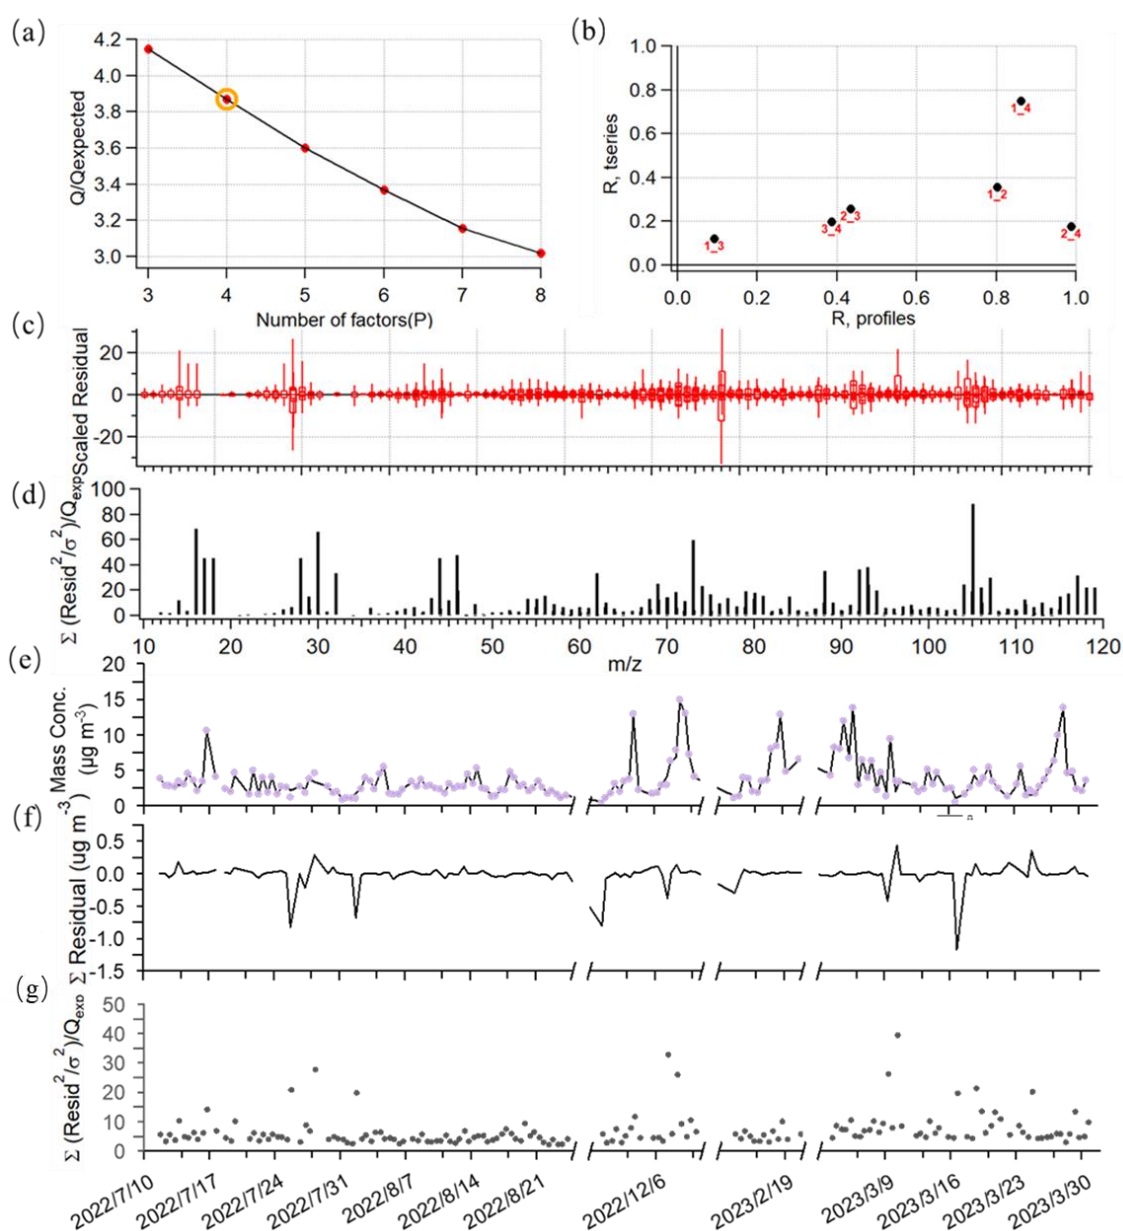

Figure S1. Summary of critical diagnostic plots of the PMF results for the 4-factor solution of WSOA: (a) Q/Q_{exp} as a function of the number of factors (P from 3 to 8). For the best solution (4-factor); (b) cross-correlations of the time series and spectral profiles among the four factors; (c) the box and whiskers plot showing the distributions of scaled residuals for each m/z ; (d) the Q/Q_{exp} values for each m/z ; (e) time series of the measured and the reconstructed WSOA mass loadings; (f) variations of the residuals of the fit; (g) the Q/Q_{exp} values for each sample.

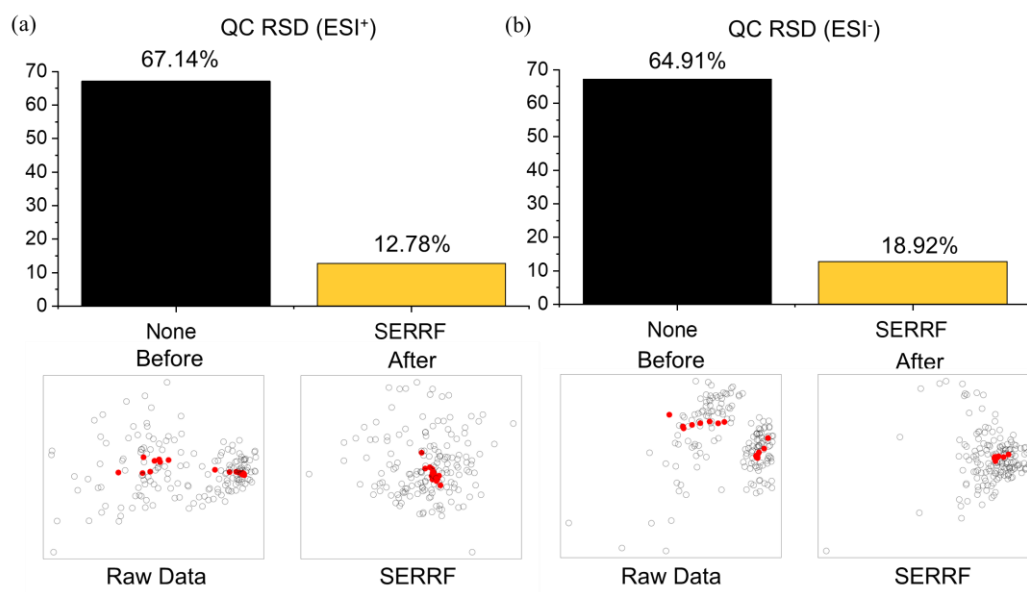

Figure S2. Relative standard deviations before and after the SERRF normalization (The gray and red markers represent real samples and QC samples, respectively). (a) ESI⁺ mode, (b) ESI⁻ mode.

Figure S3. Scatter plot of the molar concentrations of cations versus anions (SS: Summer season; CS: Cold season).

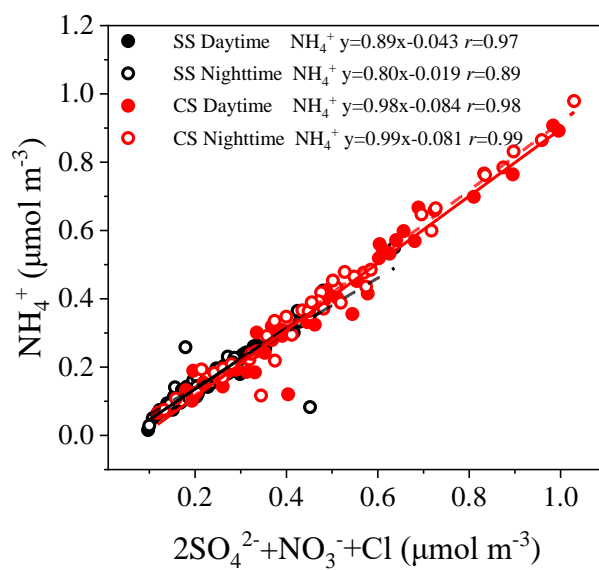

Figure S4. Scatter plot of the molar concentrations of ammonium versus sum of sulfate, nitrate and chloride (SS: Summer season; CS: Cold season).

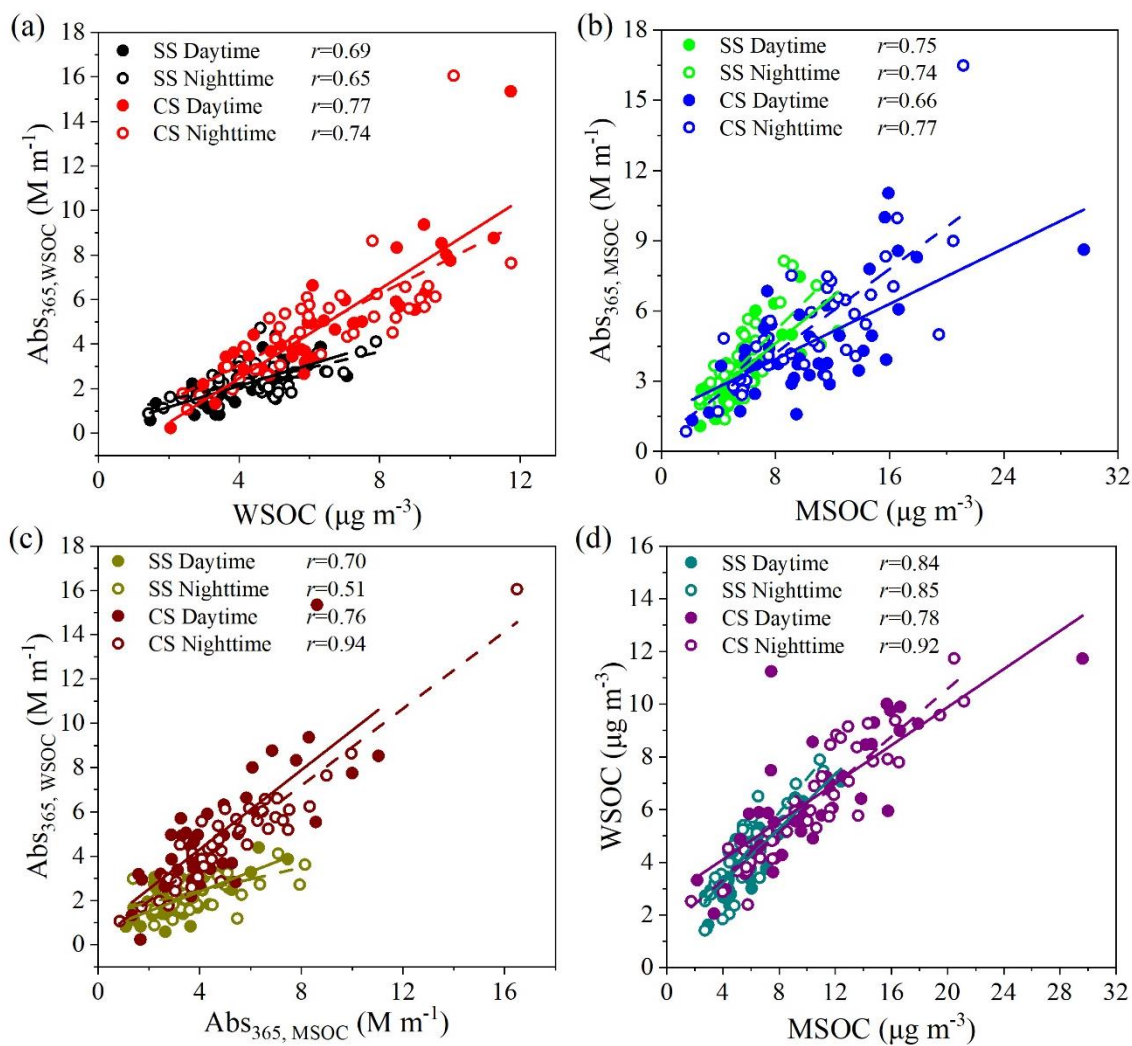

Figure S5. Scatter plots of: (a) light absorption at 365 nm of WSOC ($Abs_{365, WSOC}$) versus WSOC concentrations; (b) light absorption at 365 nm of MSOC ($Abs_{365, MSOC}$) versus MSOC concentrations; (c) WSOC versus MSOC, and (d) $Abs_{365, WSOC}$ versus $Abs_{365, MSOC}$.

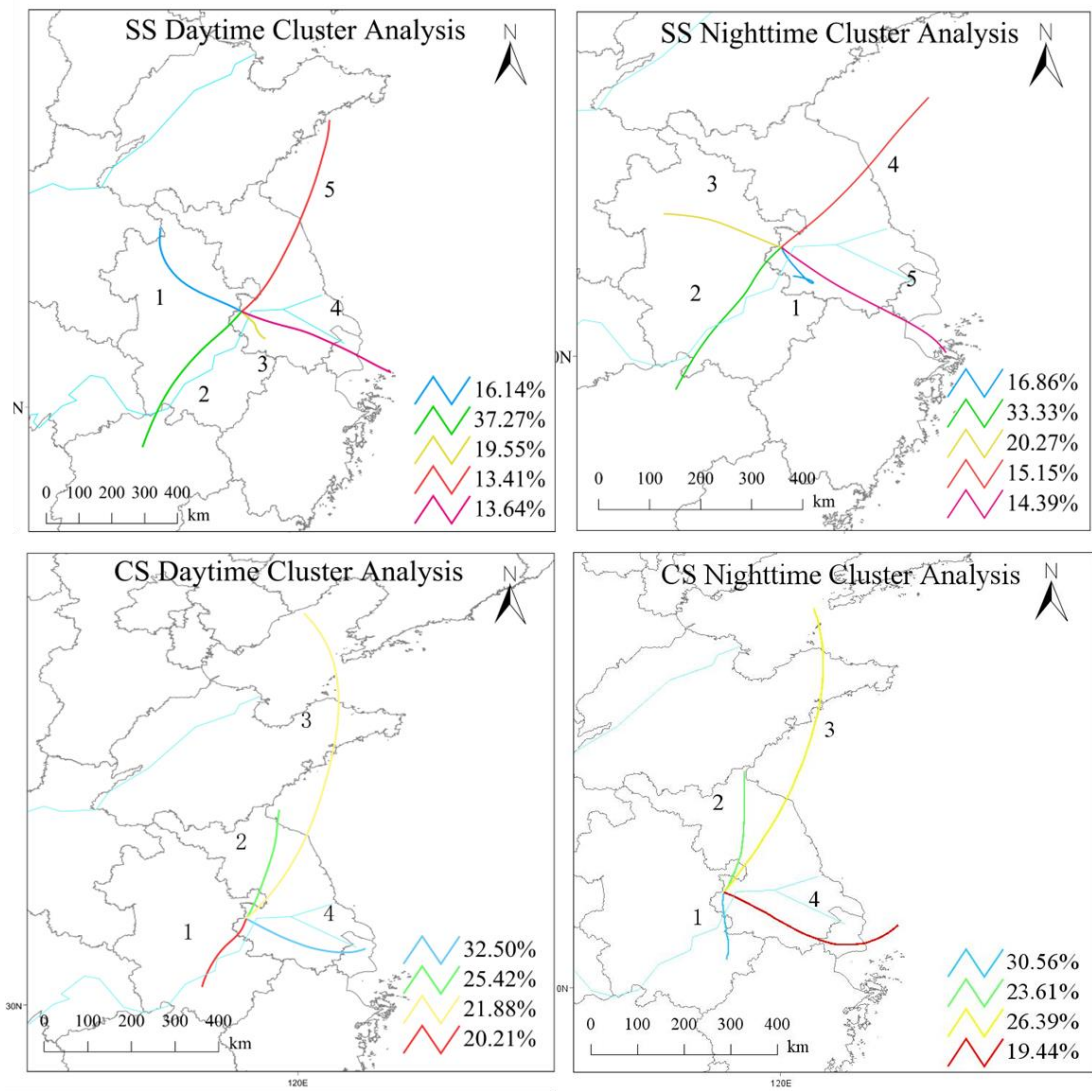

Figure S6. Clustered backward trajectories of different sampling periods.

Figure S7. Scatter plot of the reconstructed Abs₃₆₅ from the multilinear regression versus measured Abs₃₆₅.

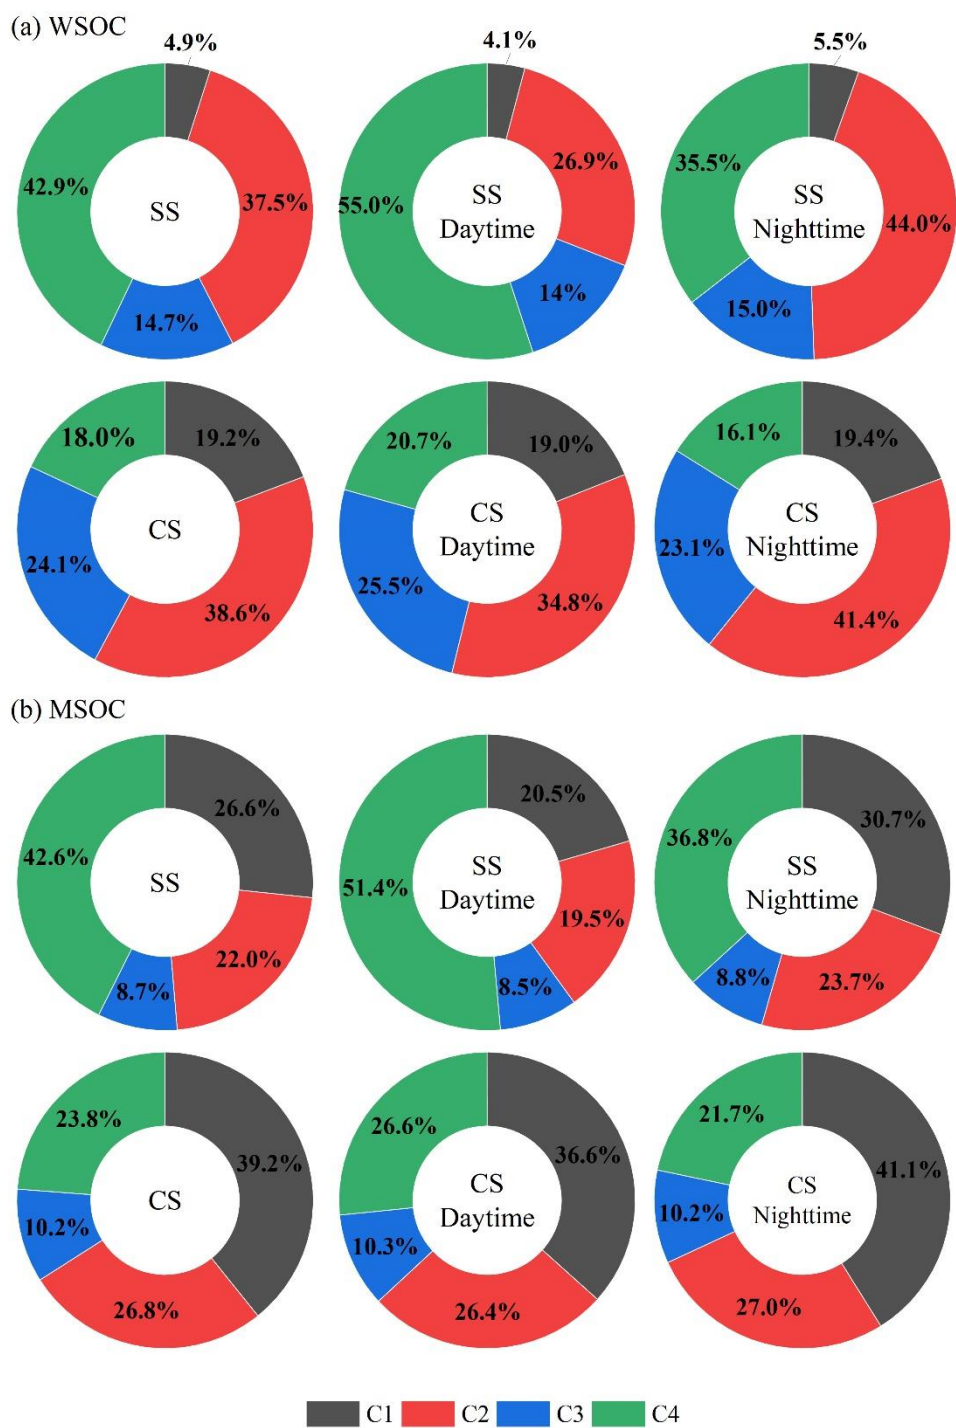

Figure S8. Average contributions of the PARAFAC-derived fluorescent components of (a) WSOC and (b) MSOC during different periods.

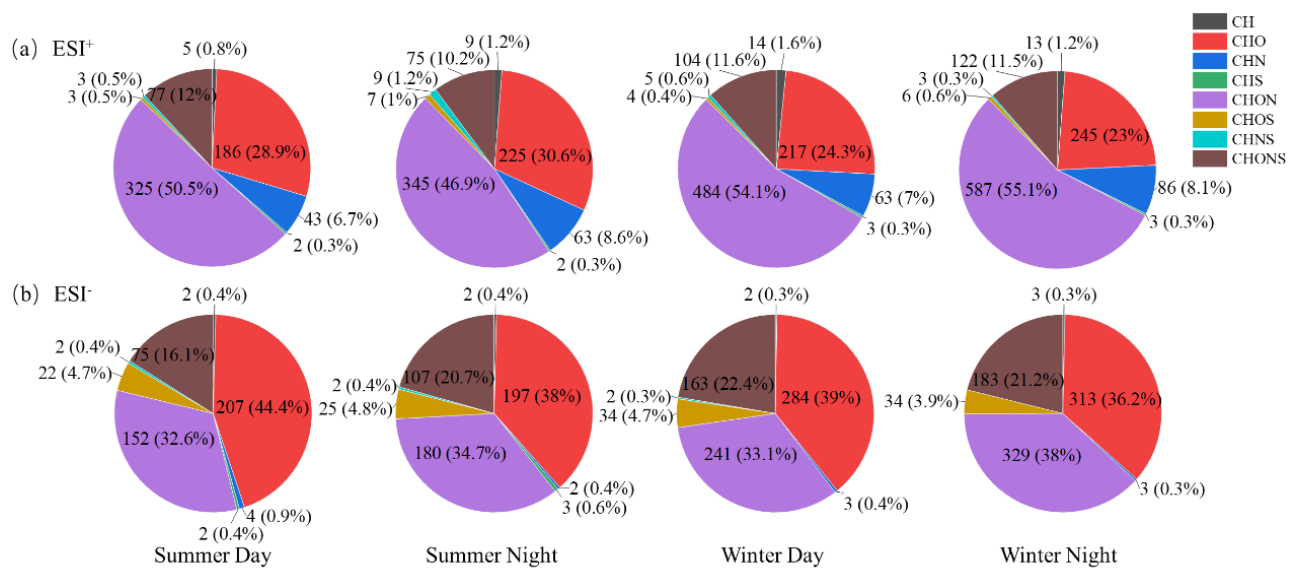

Figure S9. Numbers and number fractions of different types of compounds identified during different periods. (a) ESI⁺ mode, (b) ESI⁻ mode.

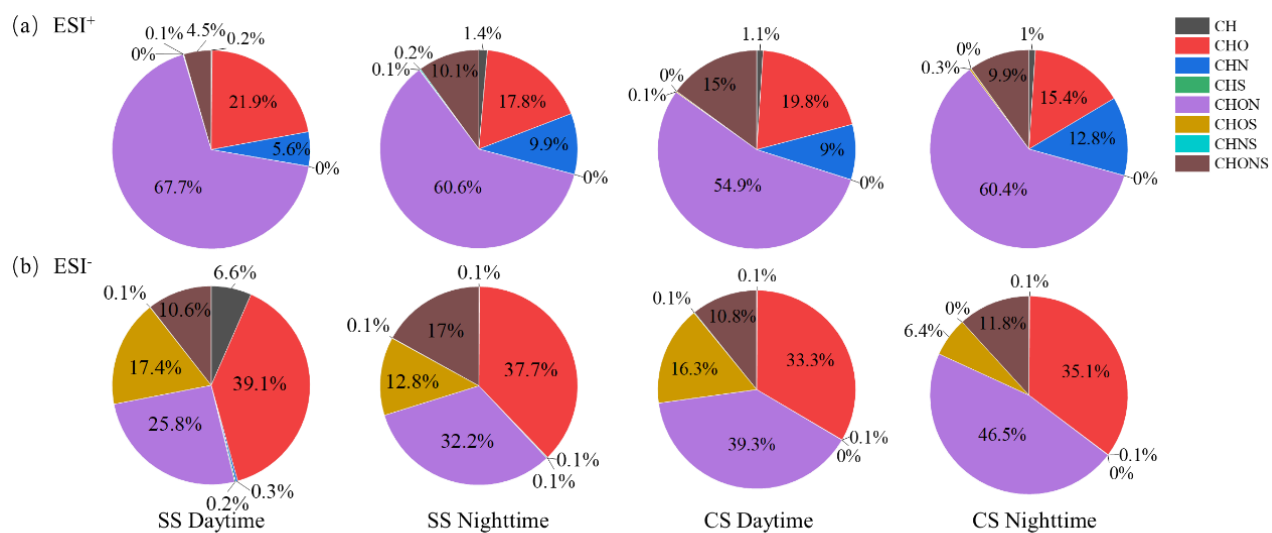

Figure S10. Contributions of the signal relative abundance of different types of compounds identified during different periods. (a) ESI⁺ mode, and (b) ESI⁻ mode.

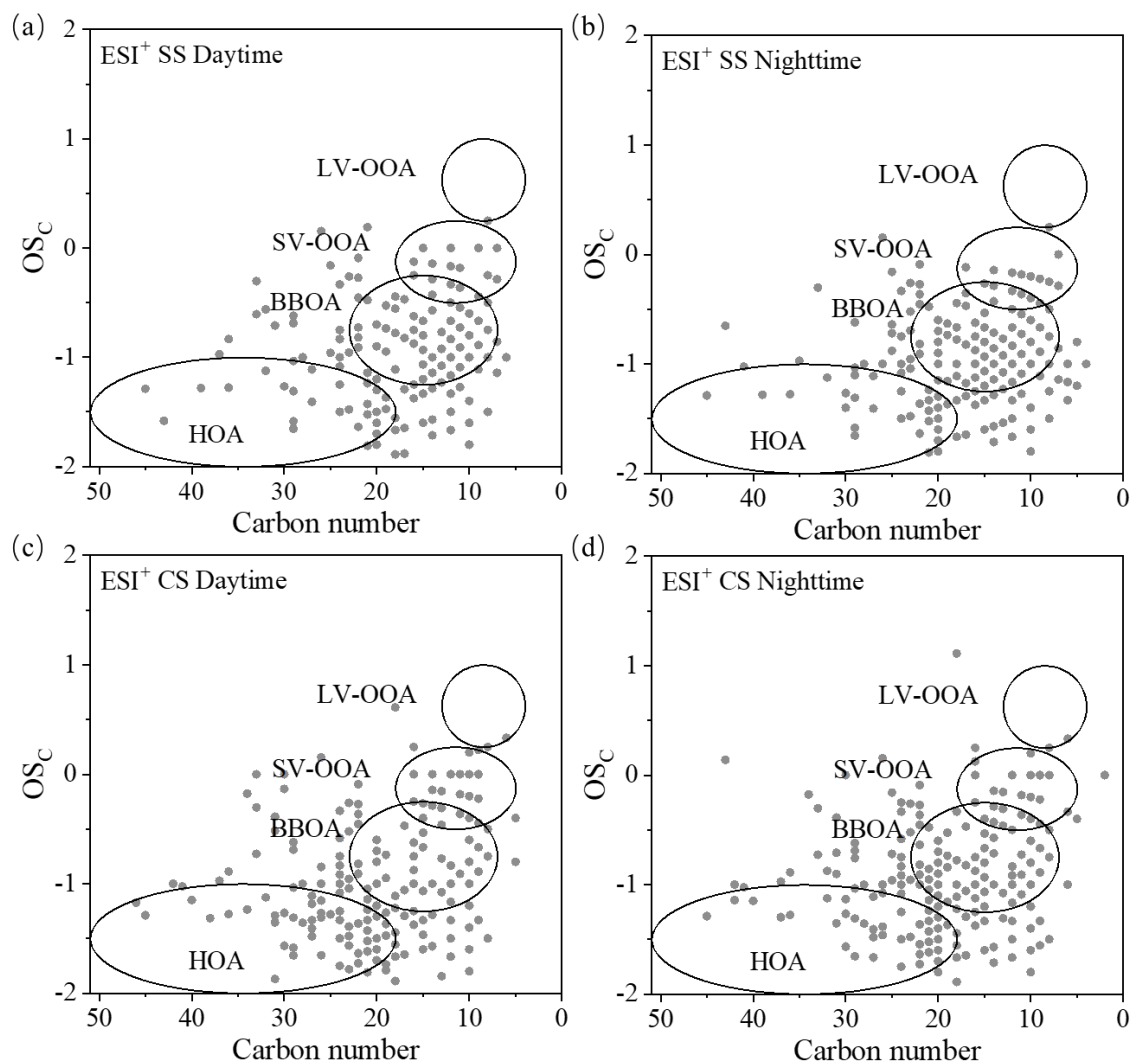

Figure S11. Scatter plots of the carbon oxidation state (OS_c) versus carbon number for all CHO compounds in ESI^+ mode during different periods. (a) SS daytime, (b) SS nighttime, (c) CS daytime, and (d) CS nighttime. The circled areas represent those from fossil fuel combustion hydrocarbon-like OA (HOA), biomass burning OA (BBOA), semi-volatile oxygenated OA (SV-OOA) and low-volatility oxygenated OA (LV-OOA) (Kroll et al., 2011).

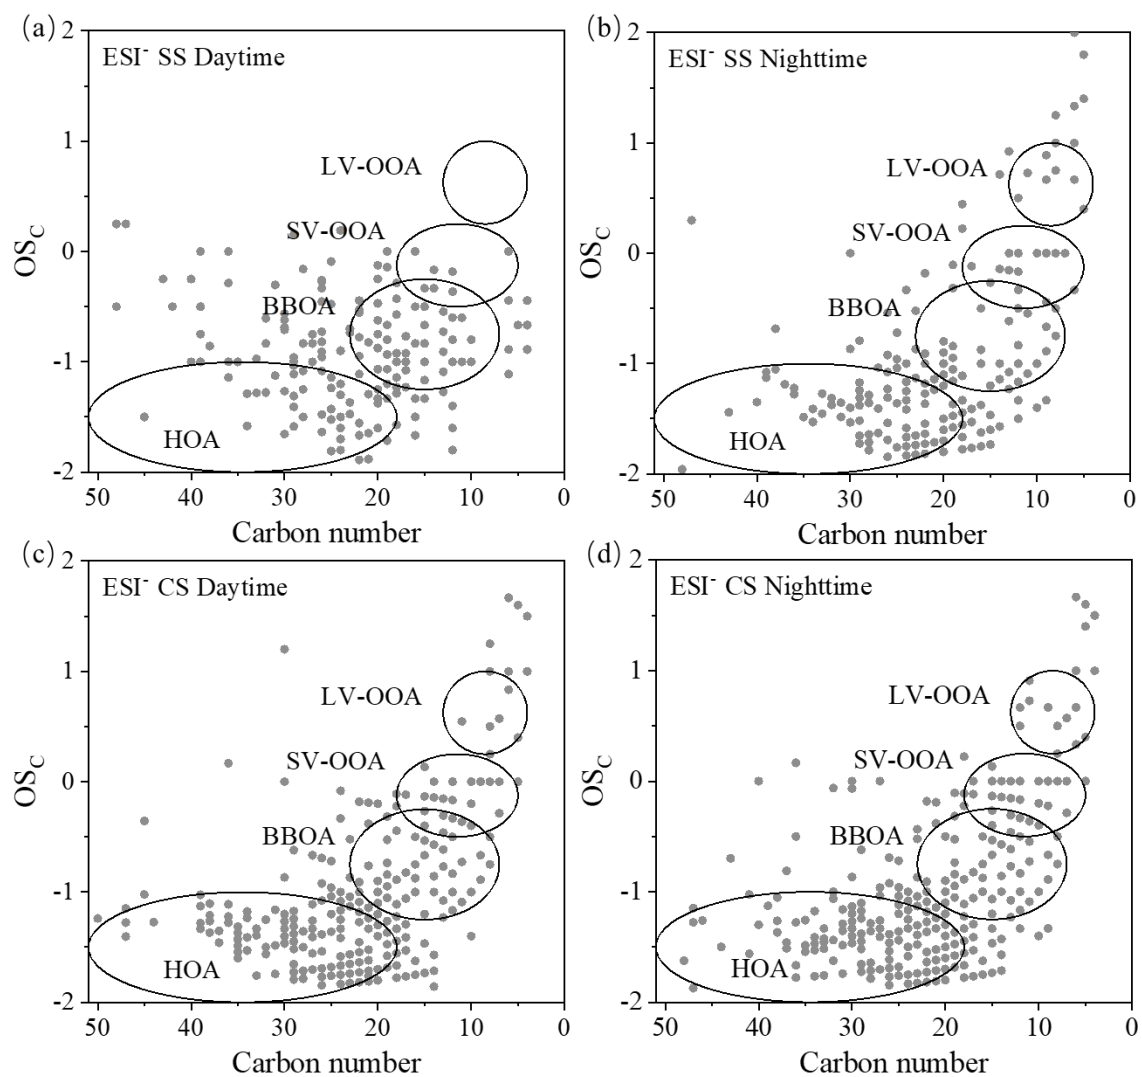

Figure S12. Scatter plots of the carbon oxidation state (OS_c) versus carbon number for all CHO compounds in ESI⁻ mode during different periods. (a) SS daytime, (b) SS nighttime, (c) CS daytime, and (d) CS nighttime. Meanings of the circled areas are same as those described in Figure S11.

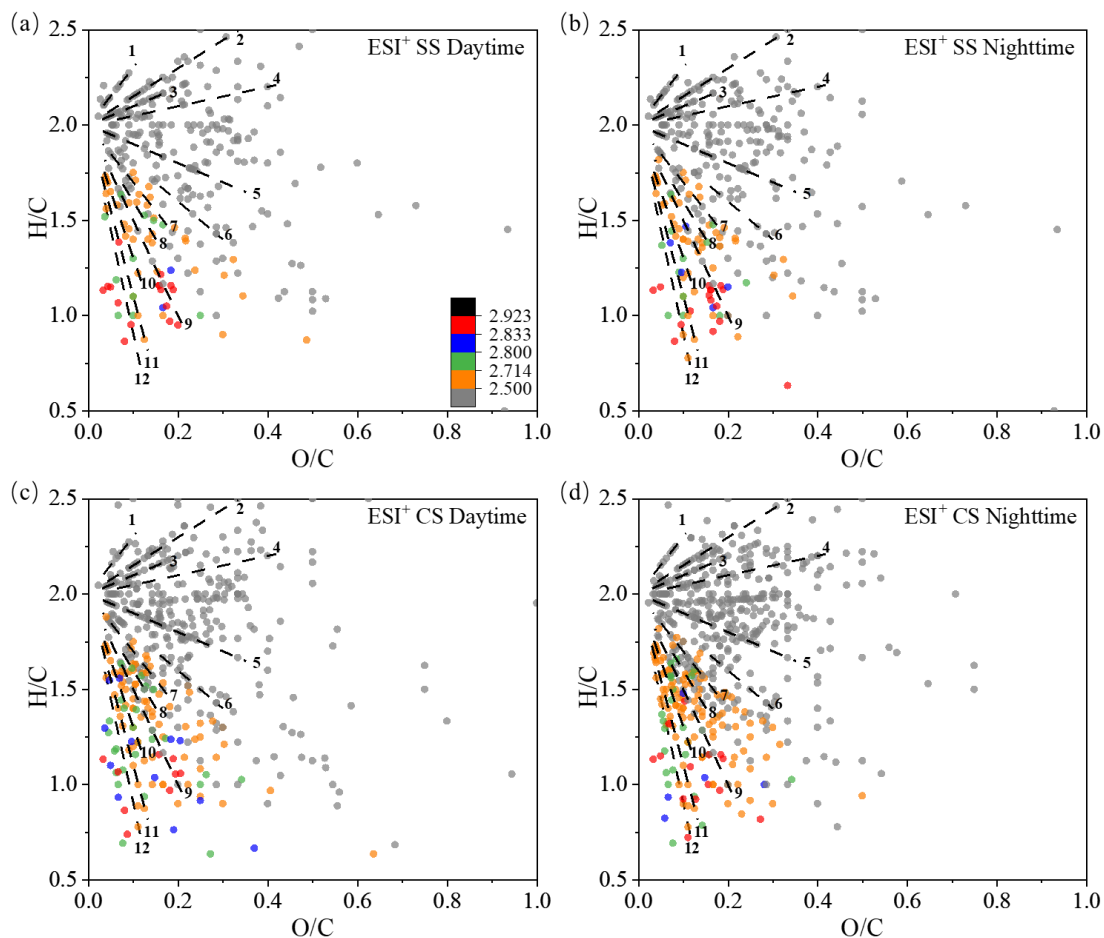

Figure S13. Van Krevelen diagram for CHON compounds detected in ESI⁺ mode during different periods. (a) SS daytime, (b) SS nighttime, (c) CS daytime, and (d) CS nighttime. The markers with different colors represent aliphatic compounds ($X_c < 2.50$), aromatic benzene ring structures ($2.50 \leq X_c < 2.71$), naphthalene ring structures ($2.71 \leq X_c < 2.80$), anthracene ring structures ($2.80 \leq X_c < 2.83$), and pyrene ring structures ($2.83 \leq X_c < 2.92$), respectively (Mao et al., 2022); Different dash lines represent different series of compounds.

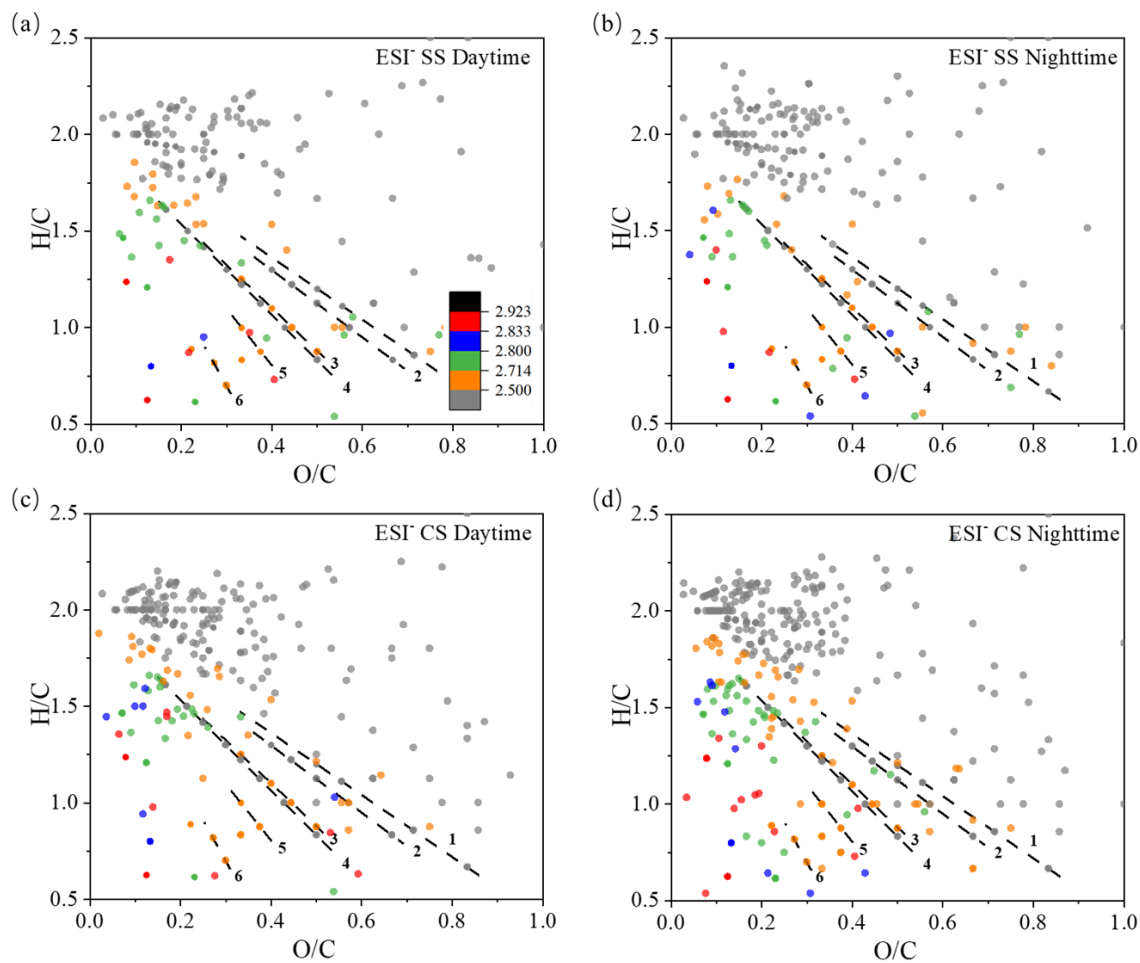

Figure S14. Van Krevelen diagram for CHON compounds detected in ESI mode during different periods. (a) SS daytime, (b) SS nighttime, (c) CS daytime, and (d) CS nighttime. Meanings of the colored values and dash lines are same as those described in Figure S13.

Figure S15. Van Krevelen diagram for CHN compounds detected in ESI⁺ mode during different periods. (a) SS daytime, (b) SS nighttime, (c) CS daytime, and (d) CS nighttime. Meanings of the colored values and dash lines are same as those described in Figure S13.
