31

32 **Abstract:**

33 Our study reveals that the negative phase of the Pacific Decadal Oscillation (PDO-) leads to
34 increased winter (DJF) snowfall in the Karakoram and Western Himalayas (KH) from 1940 to
35 2022. Interdecadal variations in DJF snowfall during the PDO- are attributed to deep convection
36 and adiabatic cooling near the tropopause in both the northwest Pacific and KH region.
37 Additionally, a wave-like pattern characterized by a trough (anomalous cyclone) north of KH and a
38 ridge (anomalous Tibetan Plateau anticyclone) east of KH in the upper atmosphere, along the
39 northward shift of the DJF Subtropical Jet (STJ) was observed. A strong positive correlation
40 between DJF STJ strength and DJF snowfall in KH as well as a significant negative correlation
41 between DJF STJ strength and DJF PDO, suggests a wave response over KH to the direct forcing
42 over the northwest Pacific Ocean. The intensified STJ across KH results in higher frequency of
43 Western disturbances, leading to anomalous moisture convergence and increased DJF precipitation
44 in the region during the PDO-. These findings hold significant implications for the decadal
45 predictability of winter snowfall in KH by the various phases of PDO.

46

47 **1) Introduction:**

48 Glaciers in the Karakoram and Western Himalaya (KH) exhibit unique stability compared to other
49 alpine glaciers (known as the ‘Karakoram Anomaly’; Hewitt, 2005; Kaab et al., 2012; Gardelle et
50 al., 2013; Kapnick et al., 2014; Forsythe et al., 2017; de Kok et al., 2018; Farinotti et al., 2020;
51 HIMAP, 2020). Winter snowfall plays a significant role in preserving the local snowpack and
52 sustaining the glacial mass balance at higher elevations (Tahir et al., 2011; Bolch et al., 2012;
53 Ridley et al., 2013; Cannon et al., 2015; Dimri et al., 2015), and controls almost 60% of the
54 variability in glacier mass balance in the KH region (Kumar et al., 2019). The decline in average
55 and minimum summer temperatures, along with significant increases in winter, summer, and annual
56 precipitation, have been proposed as crucial factors influencing the stable glacier budget of the KH
57 in recent decades (Archer and Fowler, 2006; Forsythe et al., 2017).

58 The KH receives around 50% of its annual precipitation as snowfall from western disturbances
59 (WDs) (Lang and Barros, 2004; Barros et al., 2006; Bookhagen and Burbank, 2010; Hunt et al.,
60 2024). Furthermore, WDs account for more than 65% of all winter snowfall and nearly 53% of total
61 winter precipitation in the KH (Javed et al., 2022). However, using a less conservative method,
62 Midhuna et al. (2020) found that WDs account for about 80% of winter precipitation in KH. WDs
63 are upper-level troughs in the subtropical westerly jet (STJ), which grow via baroclinic instability

64 (Norris et al., 2015; Cannon et al., 2017; Hunt et al., 2018). Strong WDs are associated with deep
65 uplift to the east of their centre and drive moist lower-tropospheric southwesterlies from the Arabian
66 Sea (Dimri and Dash, 2012; Hunt et al., 2018), resulting in heavy precipitation along the foothills
67 and mountains of KH region (Baudouin et al., 2020). The snowfall from WDs in the KH is heavily
68 influenced by the complex topography of the region, as well as by synoptic and mesoscale factors
69 (Cannon et al., 2015; Norris et al., 2015, 2017, 2018). Subsequent snowmelt in the following spring
70 and summer seasons and associated runoff serve as major sources of downstream river flow and
71 provide relief from drought to populations that are vulnerable to water stress (Bolch et al., 2012;
72 Hewitt et al., 2014; Rana et al., 2019; Pritchard et al., 2019).

73

74 However, the main climatic drivers affecting seasonal precipitation, and hence glacial mass balance
75 in the region are only partially understood (Cannon et al., 2015). WD activity during winter season
76 over the KH has been reported to be influenced by several global climate forcings such as North
77 Atlantic Oscillation/Arctic Oscillation (Yadav et al., 2009; Syed et al., 2010; Filippi et al., 2014;
78 Basu et al., 2017; Midhuna and Dimri, 2019; Hunt and Zaz, 2022), El Niño–Southern Oscillation
79 (ENSO) (Yadav et al., 2010; Dimri, 2013; Kar and Rana, 2014; Cannon et al., 2017; Kamil et al.,
80 2019; Rana et al., 2019; Bharati et al., 2024), Polar/Eurasian Pattern and Siberian High (Wu and
81 Wang, 2002; Cannon et al., 2014), Madden–Julian Oscillation (Barlow et al., 2005; Cannon et al.,
82 2017) and Indian Ocean Dipole (IOD) (Yadav et al., 2007; Hoell et al., 2013) on intraseasonal and
83 interannual timescales. In particular, the ENSO exerts the strongest influence on the interannual
84 variability of winter precipitation in KH (Rana et al., 2019). One of the key aspects of ENSO
85 teleconnection to Indian Himalayas is the southward shift in the latitude of the winter STJ over the
86 KH during the positive phase of ENSO (Cannon et al., 2014, 2017), which leads to heavier WD
87 precipitation as their tracks move closer to their primary moisture source, the Arabian Sea (Bharati
88 et al., 2024).

89

90 Precipitation gauges in the Himalayas are sparse and recognised as inadequate for accurately
91 measuring snowfall (Anders et al., 2006; Rana et al., 2015). While satellite records of precipitation
92 are available, they cover only a limited time frame, whereas our study requires long-term data to
93 analyse the interdecadal variability of precipitation over the KH region. We currently have an 85-
94 year-long reanalysis from ERA5, which has demonstrated a high degree of similarity in both the
95 quantity and variability of winter precipitation across all time scales when compared to observations

96 and satellite data in the KH region (Baudouin et al., 2020). The long dataset from ERA5 is
97 sufficient to examine the interdecadal variability of DJF snowfall over KH. The low-frequency
98 modes of atmospheric variability such as the Pacific Decadal Oscillation (PDO), Inter-decadal
99 Pacific Oscillation (IPO) (Mantua et al., 1998; Zhang et al., 1997; Power et al., 1999; Deser et al.,
100 2004; Dai, 2013), and the Atlantic Multi-decadal Oscillation (AMO) (Enfield et al., 2001) are
101 known to modulate the regional climate of the Northern Hemisphere over inter-decadal to multi-
102 decadal timescales. Among these, the PDO is the dominant mode of SST oscillation in the North
103 Pacific, influencing long-term precipitation patterns globally (Dettinger et al., 1998; Krishnamurthy,
104 2013, 2014; Wang et al., 2014; Dong and Dai, 2015; Yang et al., 2017; Wu and Mao, 2016; Qin et
105 al., 2017; Aggarwal et al., 2023). For example, Indian monsoon rainfall and autumn precipitation in
106 North Central China were found to have an inverse relationship with PDO (Krishnan and Sugi,
107 2003; Krishnamurthy, 2014; Qin et al., 2017). According to Aggarwal et al. (2023), the PDO has a
108 stronger positive correlation with pre-monsoon precipitation in the northwest Himalayas compared
109 to the ENSO and IOD, leading to a significant decrease in precipitation in recent decades. However,
110 there remains a significant gap in our understanding of the PDO's impact on precipitation over the
111 Himalayas during both monsoon and non-monsoon seasons.

112

113 The current study aims to address this knowledge gap by examining the modulation of the
114 interdecadal variability of winter snowfall over KH by PDO. Our study aims to understand the
115 potential influence of the PDO on the Karakoram anomaly, which deviates from the general climate
116 change patterns observed in the KH region and other mountainous areas. The main objective of this
117 study are: (1) To examine the spatial distribution of decadal snowfall in KH in different phases of
118 PDO, (2) how the PDO adjusts global circulation patterns, leading to changes in the STJ, and (3)
119 how these changes cause impact on a local scale over the KH through WDs and moisture transport.

120

121 **2) Data and Methods:**

122 **2.1 Data**

123 **2.1.1) Meteorological data**

124 The study uses meteorological data including geopotential height, zonal (u) and meridional wind (v)
125 at 200 hPa level, vertically averaged temperature from 500 to 300 hPa level, vertically integrated
126 moisture flux (VIMF), vertically integrated moisture flux convergence (VIMFC), and global sea

127 surface temperature (SST) obtained from the European Centre for Medium-Range Weather
128 Forecasts (ECMWF) ERA5 reanalysis from 1940 to 2022. The jet latitude and strength are
129 computed by 200 hPa zonal winds over the region ($50^{\circ} - 80^{\circ}\text{E}$, $10^{\circ} - 60^{\circ}\text{N}$). The jet latitude is the
130 mean of the latitudes with the largest value of u for each longitude and jet strength is the mean
131 value of u along these latitudes. ERA5 data have global coverage at hourly frequency and a
132 horizontal resolution of 0.25° .

133

134 **2.1.2) Precipitation data**

135 Precipitation in the KH is mainly observed through satellite derived and reanalysis products
136 (Bosilovich et al., 2008; Joshi et al., 2012; Ménégoz et al., 2013; Palazzi et al., 2013; Rana et al.,
137 2015; Kishore et al., 2016; Baudouin et al., 2020) due to limited and unreliable observations from
138 ground stations in this complex topographical region (Anders et al., 2006; Bookhagen and Burbank
139 2006; Strangeways, 2010; Rana et al., 2015; Dahri et al., 2018). The ERA5 reanalysis has
140 frequently been used for precipitation and snow in recent studies over the KH (Dahri et al., 2018;
141 Baudouin et al., 2020; T. Singh et al., 2021) and neighbouring mountainous areas (Hu and Yuan,
142 2020; Li et al. 2021; Dollan et al., 2014). ERA5 closely matches the most reliable gridded
143 measurements over KH in terms of amount, seasonality, and variability across all timescales during
144 winter (Baudouin et al., 2020). However, the accuracy of precipitation datasets varies depending on
145 the season in the region. We choose ERA5 due to its long period, allowing decadal-scale analysis
146 where other datasets do not.

147 To assess the performance of ERA5 precipitation, we compared the ERA5 precipitation with
148 various gridded precipitation datasets over the KH, including reanalysis datasets from ECMWF
149 ERA5-land, Modern Era Retrospective-analysis for Research, Applications version 2 (MERRA2),
150 and High Asia Refined analysis version 2 (HAR v2), as well as rain gauge, and satellite data from
151 Climate Research Unit version 7 (CRU_TS v7), Global Precipitation Climatology Center version
152 2022 (GPCC), Global Precipitation Climatology Project version 3.2 (GPCP v3.2), Asian
153 Precipitation - Highly-Resolved Observed Data Integration Towards Evaluation (APHRODITE
154 MA_v1101), CPC-Merged Analysis of Precipitation (CMAP), Tropical Rainfall Measuring Mission
155 (TRMM) Multi-satellite Precipitation Analysis (TMPA) 3B43, and Global Precipitation
156 Measurement mission-Integrated Multi-satellite Retrievals version 7 (GPM_IMERG v7).

157 We computed the linear correlation coefficient between area-averaged precipitation over the KH
158 region (cropped by the shapefile of the traditional boundaries of the Karakoram-Western and

159 Central Himalaya; highlighted by a green box in Fig. 2a&b) in ERA5 and numerous other
 160 precipitation datasets. A strong correlation was seen between DJF ERA5 precipitation and rain-
 161 gauge-based precipitation products, including GPCC, GPCP, and CRU, with the exception of
 162 CMAP, which exhibited a correlation coefficient of 0.51 (Table 1). All reanalysis products,
 163 including ERA5 exhibit similar DJF precipitation variability as seen in observational and satellite
 164 datasets over the KH region. The variability of ERA5 precipitation in the KH region aligns closely
 165 with all available gridded datasets, despite the presence of biases in ERA5 precipitation across this
 166 region. Since most of DJF precipitation in KH occurs as snowfall (Fig. 1b), we utilize ERA5
 167 snowfall data to examine the decadal variability of snowfall in the KH (73° – 78°E, 33° – 38° N).

168 **Table:1 Correlation coefficients of DJF precipitation based on monthly reanalysis, rain-gauge**

170

171 **2.1.2) PDO index**

172 The PDO index from the National Oceanic and Atmospheric Administration National Climate Data
 173 Center (NOAA-NDC) (<https://www.ncei.noaa.gov/access/monitoring/pdo/>) is employed to describe
 174 the interdecadal variability of the Pacific Ocean over the period 1940 to 2022.

175

176 **2.1.3) Western disturbance data**

177 WD statistics are computed from the WD track catalogue described in Hunt et al., (2018) and
 178 Nischal et al., (2022), which is based on ERA5 reanalysis data that is spectrally truncated to T42 to
 179 remove noise and small-scale structures. The tracking algorithm detects WDs by identifying upper-
 180 tropospheric regions of positive relative vorticity averaged between 450 hPa and 300 hPa, with the
 181 locations of candidate WDs identified as centroids of these regions. The candidate WDs are then
 182 further refined by only accepting those: 1) whose locations are linked through time to form tracks
 183 that generally follow the westerly steering winds associated with the STJ, 2) that persist for at least
 184 48 hours, and 3) that pass through north India (50°–77°E, 22°–42.5°N). The northern limit of this
 185 box, 42.5°N, is more poleward than has been used previous studies (36.5°N). This allows us to
 186 better capture WD impacts over the Karakoram.

187

188 **2.2 Methods**

189 **2.2.1) Lanczos filter**

190 To isolate the decadal signals, we linearly detrended all meteorological variables and the PDO index
 191 for DJF. These datasets were then filtered using a 9-year running mean Lanczos filter, which is a
 192 low-pass filter based on the sinc convolution (Duchon et al., 1979). The positive (negative) phase of
 193 PDO is defined as years when the filtered DJF PDO index is greater than (less than) zero. We define
 194 the negative epoch (PDO-) as two negative phases of PDO that occurred from 1948 to 1977 and
 195 1989 to 2014, and the positive epoch (PDO+) as a positive phase of PDO that occurred from 1978
 196 to 1988 (Fig.1b). Also, the detrended variables are used to conduct correlation and composite

197 analyses. The Student's and Welch's t-test are used in the study to determine the statistical
198 significance of correlation and composite analyses, respectively.

199

200 **2.2.2) Wavelet analysis**

201 The PyCWT library (<https://pycwt.readthedocs.io/en/latest/tutorial/cwt/>) is used to calculate the
202 cross-wavelet power spectrum. This library is based on the implementation by Torrence and Compo
203 (1998). We employed the cross wavelet transform to calculate the wavelet spectrum between
204 monthly time series of the PDO index and the area averaged monthly ERA5 snowfall over the KH
205 region. The cross wavelet transform finds regions in time frequency space where the time series
206 show high common power.

207

208 **3) Results:**

209 **3.1) PDO and KH winter snowfall**

210 This study aims to examine the long-term variability in DJF snowfall in the KH region in relation
211 with the PDO from 1940 to 2022. There is a significant negative correlation between the lowpass-
212 filtered and detrended time series of DJF PDO and DJF snowfall in the KH (Fig 1b), with a
213 coefficient of -0.51. However, the PDO is not a single phenomenon, but rather a set of processes
214 that occur in both the tropics and the extratropics and reflects the influence of various processes
215 occurring at distinct timescales (Newman et al., 2016). More precisely, elevated sea surface
216 temperature (SST) in the eastern tropical Pacific is linked to lower SST in the central and western
217 North Pacific, while higher SST is observed in the eastern North Pacific (Deser et al. 2004;
218 Newman et al., 2016). Thus, decadal variability in the North Pacific SSTs is linked to tropical
219 Pacific decadal variability, specifically in terms of the long-lasting seasonal ENSO patterns
220 (Newman et al., 2011; Wittenberg et al. 2014) as well as the ENSO like multidecadal oscillation
221 (i.e., IPO; Zhang et al., 1997). Occasionally, the AMO may also influence multidecadal variability
222 of the PDO (Zhang and Delworth, 2007). After excluding of the influences of ENSO and IPO, the
223 correlation slightly increases to -0.53 and -0.54, and rises to -0.67 upon the elimination of the
224 AMO's impact.

225

226 The spatial structure of the correlation between PDO and KH snowfall in winter (Fig. 2a) is
227 significantly negative along the western and central Himalayas and much of the southern
228 Karakoram, but positive over the Tibetan Plateau and north India. The snowfall in the KH region
229 during the boreal autumn (SON) and spring (MAM) has a strong positive correlation with the PDO
230 (not shown), whereas the summer monsoon season (JJA) displays a weak but positive correlation
231 with the PDO. The different signs of the correlation suggest that the dynamic processes driving KH
232 snowfall either vary by season, or the seasonal influence of the PDO on KH snowfall changes.

233

234 Figure 2b displays the regional distribution of the difference in detrended DJF snowfall between the
235 negative and positive phases of PDO, hereafter referred to as PDO- and PDO+, respectively. The
236 difference is significantly positive in the KH area, particularly over the southern part of the
237 Karakoram region. DJF snowfall in the KH accounts for around 80-90% of total annual snowfall
238 during the time period (not shown). During PDO+, DJF snowfall over KH is nearly 7% lower than
239 the average seasonal snowfall, while during PDO- it is about 6% higher. It indicates that the
240 difference in DJF snowfall in KH varies significantly depending on the phase of the PDO across
241 several decades.

242

243 This strong relationship between PDO and snowfall in the KH is also demonstrated through a cross-
244 wavelet frequency spectrum analysis between the unfiltered monthly time series of PDO index and
245 snowfall over the KH from 1940 to 2022 (Fig. 2c). The band of strong and significant power in the
246 period of ~ 1 year in the cross-wavelet indicates that the PDO and KH snowfall both have strong
247 interannual variability. The well-known influence of ENSO on snowfall in the region (operating on
248 interannual timescales) during DJF is also slightly modulated by the low-frequency oscillation of
249 PDO. Another band of significant power exists in the 6-15 year range, indicating a high decadal
250 scale correlation between these two time series. The significant power in the 6-15-year range
251 occurred between 1940 and 1970 and again from 1998 to 2015, coinciding with the negative phases
252 of the PDO. An insignificant weak power appeared within the same range from 1971 to 1988,
253 coinciding with the positive phase of the PDO. A long band of strong power exists throughout the
254 16–20-year range, observed from 1950 to 1990, while a weaker power is shown from 2000 to 2022.
255 This indicates that the low-frequency variability of KH snowfall is influenced by decadal
256 oscillations over various time scales, while the interdecadal variability of KH snowfall is found to
257 influenced by the phase of the PDO.

259 **3.2) Sea Surface temperature (SST) variability during DJF**

260 Figure 3a illustrates the well-known positive (or warm) phase of the PDO over the North Pacific,
261 shown as a correlation between lowpass filtered and detrended sea surface temperature (SST) and
262 PDO index during DJF. The correlation pattern also reveals a strong El-Nino like pattern in the
263 eastern equatorial-tropical Pacific Ocean. For comparison, the correlation pattern between the DJF
264 SST anomalies and the DJF snowfall anomalies in the KH region is shown in Figure 3b. This
265 correlation strongly resembles the negative (or cool) phase of the PDO over the North Pacific
266 Ocean. It is characterised by positive SST anomalies in the northwest Pacific and negative SST
267 anomalies in the northeast Pacific. Additionally, there are negative SST correlations in the tropical
268 eastern Pacific region and eastern Indian Ocean adjacent to Western Australia, while positive
269 correlations are observed in the southwest Indian Ocean and across the northwest Atlantic Ocean.
270 The correlation pattern in the southern Indian Ocean reveals the subtropical Indian Ocean Dipole
271 signature (positive phase) (Behera & Yamagata, 2001; Yamagami & Tozuka, 2014).

272

273 **3.3) Upper atmosphere circulation response with PDO and snowfall**

274 To understand the anomalous atmospheric circulations that connect the PDO with anomalous DJF
275 snowfall in the KH region, we computed the correlation of 200 hPa geopotential height with both
276 the DJF PDO index (Fig. 4a) and DJF snowfall (Fig. 4b). The correlation pattern between the PDO
277 and upper-level geopotential height shows a prominent upper-level trough over east China, Japan
278 and the northwest Pacific, which is known as East Asian trough (EAT; Qin et al., 2018; Yin and
279 Zhang, 2021). In contrast, the correlation pattern over the Caspian Sea, KH, and Lake Baikal region
280 is associated with positive geopotential height anomalies. The EAT is a well-known upper
281 atmospheric response to the positive phase of PDO to the East Asia-North Pacific region during the
282 Northern Hemisphere winter (Newman et al, 2016; Qin et al., 2018; Yin and Zhang, 2021). The
283 intensity of the EAT is strongly linked to the strength of the winter monsoon in East Asia and the tilt
284 in the EAT axis is connected to midlatitude baroclinic processes, such as the eddy-driven jet or WD
285 tracks over the East Asia-North Pacific region (Wang et al., 2009). Therefore, changes in location
286 and intensity of the EAT can lead to, or otherwise indicate, regional climate anomalies, such as
287 temperature in the upper troposphere which subsequently influence DJF precipitation in East Asia
288 as well as the KH during the positive phase of the PDO.

289 These patterns change sign during negative phases of PDO, when KH snowfall is enhanced,
290 implying an anomalous upper-level trough to the west of the Karakoram, consistent with increased
291 WD frequency or intensity. The correlation between upper-level geopotential height and snowfall
292 has a similar pattern to the PDO-geopotential correlation, but as expected, with reversed sign. The
293 correlation pattern exhibits a strong ridge (or a weakened EAT) over the northwest Pacific and
294 Japan characterised by the significant positive geopotential height anomalies. The negative
295 correlation to the west of the KH area shows a trough, which is stronger than the positive
296 correlation between PDO and geopotential height, indicating the linkage of seasonal snowfall to the
297 passage of WDs is stronger than the link between the PDO and WDs. Both, however, are important.
298 The appearance of the anomalous trough in both pairs of correlations implies that the PDO may
299 affect KH snowfall by somehow modulating WD activity. Therefore, it is essential to understand
300 how decadal fluctuations in DJF snowfall in the KH are driven by WDs and how the PDO
301 influences WD behaviour. This can be accomplished by investigating the DJF STJ, followed by a
302 detailed investigation of the WDs.

303

304 **3.4) Modulation of WD and Subtropical Westerly Jet by the PDO**

305 To further illustrate the above relationship between PDO and DJF snowfall in KH, we examine the
306 composite differences in 200 hPa wind, geopotential height, and temperature (Fig. 5) between PDO-
307 and PDO+. Figure 5a displays the difference in 200 hPa circulation over East Asia, Arabian
308 Peninsula and northwest Pacific region. During the PDO-, there is a large negative geopotential
309 height anomaly to the north of KH region, which extends from the Caspian Sea-Arabian Peninsula
310 to KH. Strong westerlies are observed to the south of this trough with a stronger STJ prevailing
311 across KH during the PDO-. An anomalous trough in the upper atmosphere is indicative of
312 increased WD frequency (or intensity) and the frequency of WDs is strongly affected by variations
313 in both the latitude and intensity of the STJ (Dimri et al., 2015; Hunt et al., 2017, 2018) over South
314 Asia. Therefore, we now focus on understanding the relationship between the PDO and the STJ.

315

316 Upper-level jets are thermal wind responses to upper-level meridional temperature gradients. In Fig
317 5b, we show the difference in mid-to-upper (from 500 hPa to 300 hPa) tropospheric temperature
318 between PDO- and PDO+. A quadrupole in the upper air temperature gradient is present across the
319 KH, Tibetan Plateau (TP) and the northwest Pacific region during PDO-. Over the Pacific, this is
320 effectively a direct response to the anomalous surface heating provided by the PDO. Anomalous

321 warm SSTs over the northwest Pacific lead to adiabatic cooling near the tropopause, which results
322 in deep convection over the Maritime Continent during the PDO- (e.g., Wang et al., 2016).
323 Upstream, over continental Asia, the relationship is more complicated and is probably a wave
324 response to the direct forcing over the ocean. Therefore, a strongly enhanced meridional
325 temperature gradient over the KH and TP, leading to a stronger and more meridionally-locked STJ.

326

327 Figure 5c displays the lowpass filtered time series of latitude and strength of the DJF STJ. During
328 the PDO-, the STJ tends to sit slightly further north but is also substantially stronger. The
329 correlation of the time series of the strength of DJF STJ with DJF PDO is significantly negative (-
330 0.22), and the correlation between DJF STJ strength and DJF snowfall in KH is strong positive
331 (0.51). The positive (negative) phase of the PDO enhances the movement of the STJ towards the
332 south (north) through a response to the decreased (increased) SST over the northwest Pacific and
333 modulates the cyclonic (anticyclonic) circulation over the northwest Pacific and adjacent maritime
334 continents (Matsumura & Horinouchi, 2016). During PDO-, we observed a quadrupole in the
335 anomalous upper-level temperature gradient (Fig. 5b), resulting in a negative anomaly in the
336 temperature gradient and an anticyclonic circulation (Fig. 5a) over the TP. Thus, by modulating the
337 STJ, the negative phase of the PDO leads to more frequent (more intense) WDs at slightly higher
338 latitudes than usual (e.g. into the Karakoram, where the signal is the strongest).

339

340 The presence of a stronger STJ along with a wave-like pattern of trough (anomalous cyclone) over
341 the northern region of KH, and a ridge (anomalous TP anticyclone) in the upper atmosphere,
342 increases the occurrence of WDs over KH during the PDO-. After examining the impact of the PDO
343 on the STJ, we now quantify its influence on WDs directly. Maps of the difference in the frequency
344 of DJF WDs between PDO- and PDO+ (Fig. 6a) indicate that WDs are more frequent (with a 9%
345 higher frequency) over the KH region during PDO- compared to PDO+. Also, the frequency of
346 WDs is found to be reduced by around 3% in both the northern and southern regions of the KH
347 during PDO- compared to PDO+. These WDs are observed to be more intense in the vicinity of the
348 Caspian Sea and north of the KH during PDO- rather than PDO+ (not shown).

349

350 **3.5) Atmospheric-ocean response of PDO on moisture transport in KH**

351 Increased frequency and intensity of WDs have a significant impact on precipitation in the KH and
352 surrounding region because they govern southwesterly moisture transport from the Arabian Sea
353 (Baudouin et al., 2021; Hunt and Dimri 2021). The composite difference of DJF VIMF and VIMFC
354 between PDO- and PDO+ is now examined to determine the response of moisture transport to the
355 PDO and its subsequent effect on the KH (Fig. 6b). The average difference of VIMFC between
356 PDO- and PDO+ is about $0.8 \times 10^{-5} \text{ kg m}^{-2} \text{ s}^{-1}$ within KH region. An advection of moisture from the
357 Black Sea, Red Sea, and eastern Mediterranean Sea through the Arabian Peninsula/Arabian Sea
358 towards the KH in westerly fashion is observed. The precipitation associated with WDs is mostly
359 determined by their intensity and proximity to the Arabian Sea (Baudouin et al., 2020). The
360 variations in the moisture transport across the Arabian Peninsula/Arabian Sea are not directly linked
361 to changes in VIMF over the northwest Pacific, but the presence of more WDs south of the strong
362 DJF STJ over KH clearly result in greater moisture transport towards KH during PDO-. Hence, the
363 anomalous moisture transport nearly perpendicular to KH, results in increased moisture flux
364 convergence about 16% greater during the PDO- compared to the PDO+ and leads to greater
365 precipitation in the region during PDO-.

366

367 **4) Conclusion and Discussion:**

368 The recent impacts of climate change over the KH, particularly in mean and extreme winter
369 precipitation, have been largely attributed largely to anthropogenic forcing, such as greenhouse
370 gases, aerosols, and changes in land use. However, these changes cannot be solely explained by
371 natural forcing (Krishnan et al., 2018). Oceanic conditions, especially changes in SSTs over the
372 equatorial-tropical Pacific and north Pacific, play an important role in driving interdecadal
373 variability in atmospheric circulation and hence winter precipitation over the KH.

374

375 DJF snowfall in the KH accounts for around 80-90% of total annual snowfall during the time
376 period, hence a 15% difference in DJF snowfall can have a significant influence on agriculture in
377 this region, especially since most of the rivers in this region, such as tributaries of Indus, Tarim and
378 Ganges are partially fed by snowmelt in the spring and later seasons (Armstrong et al., 2018).
379 Understanding the interdecadal variability and its relationship with the PDO is important for
380 understanding the long-term climate of the KH. We have analysed the long-term variability in
381 winter snowfall over the KH due to PDO by using ERA5 reanalysis data from 1940 to 2022. We
382 found that a strong negative correlation of -0.51 between the PDO and DJF snowfall in the KH.

383 Mean KH snowfall during DJF is approximately 6% greater than the DJF seasonal average during
384 PDO-, and 7% lower during PDO+.

385

386 PDO associated anomalous warming of SST in the northwest Pacific modulates the snowfall in the
387 KH via changes in upper-level temperatures over the Pacific and Asia. The warm SSTs lead to
388 increased deep convection and subsequent upper-tropospheric adiabatic cooling over the Pacific.
389 During PDO-, the anomalous heating of the tropospheric column over North Pacific leads to a wave
390 like pattern with an upper-level trough over the north of KH and upper-level ridge over the Tibetan
391 Plateau. This results in a stronger STJ to the west of, and over, the KH, before it is deflected
392 northwards over the Tibetan Plateau. There is a strong positive correlation between the strength of
393 DJF STJ and DJF snowfall in KH, with a correlation coefficient of 0.51, and a significant negative
394 correlation between the strength of STJ and PDO, with a correlation coefficient of -0.22 during DJF
395 at decadal scale. These results indicate a wave response over KH to the direct forcing of the north
396 Pacific Ocean.

397 These anomalous jet conditions over KH are linked to a higher occurrence of WDs across the
398 region. Using a track catalogue, we found that WDs are 9% more frequent across the KH and drop
399 by approximately 3% in both the northern and southern regions of the KH during PDO- compared
400 to PDO+. However, the WDs are found to be more intense in the vicinity of the Caspian Sea and
401 north of the KH during PDO- rather than PDO+, which is not shown in this study. This increase in
402 WD frequency results in anomalous moisture transport from the Arabian Sea, Black Sea, Red Sea,
403 and eastern Mediterranean Sea towards the KH. The moisture transport is almost perpendicular to
404 the orography of the KH, leading to a strong moisture convergence about 16% greater during the
405 PDO- compared to the PDO+ and thus increased DJF precipitation in the region during the negative
406 phases of the PDO.

407 Our findings highlight the importance of considering interdecadal variability when trying to
408 quantify the effects of anthropogenic climate change in the KH. The recent PDO- has led to
409 increased WD activity, and hence increased winter snowfall over this region, and may be masking
410 the effects of climate change. More research is needed to disentangle climate change from the
411 effects of interdecadal variability over this vulnerable region, so that policymakers can be better
412 informed. The uncertainty in the snowfall and precipitation datasets, along with the limitations of
413 the short timeseries available from reanalysis for examining decadal oscillations, are insufficient to
414 demonstrate such studies. Future long-term climate simulations could be used for subsequent work

415 if the models accurately represent the interaction between the PDO and snowfall/precipitation in
416 this region.
