33 **Text-S1 Vapor wall loss corrections for SOA yield**

34 Our study also corrected loss of vapors to the chamber wall by the first-order wall-loss
35 coefficient k_w (s^{-1}) by Zhang et al. (2014). The value of k_w use the gas-phase transport
36 parameters within a chamber. McMurry and Grosjean (1985) present a formula for k_w .

$$37 \quad k_w = \left(\frac{A}{V}\right) \frac{\left(\frac{\alpha_w \bar{c}}{4}\right)}{1.0 + \left(\frac{\pi}{2}\right) \left[\frac{\alpha_w \bar{c}}{4(k_e D_{gas})^{0.5}}\right]} \quad (1)$$

38 where A/V is the surface to volume ratio of the chamber (the ratio was 4 m^{-1} in this
39 study), α_w is the mass accommodation coefficient of vapors onto the chamber walls, and
40 10^{-5} was adopted according to the experimental results of Matsunaga and Ziemann (2010),
41 \bar{c} is the mean thermal speed of the molecules. k_e is the coefficient of eddy diffusion, and
42 0.12 s^{-1} was estimated according to the values reported by previous studies for a 4 m^3 Caltech
43 chamber (McMurry and Grosjean, 1985). D_{gas} is the molecular diffusivity. For the type of
44 molecules here, D_{gas} is $\sim 1.38 \cdot 10^{-5} \text{ m}^2 \text{ s}^{-1}$ and $\bar{c} \sim 299 \text{ m s}^{-1}$. For a given vapor molecule, the
45 mean thermal speed \bar{c} could be calculated according to the following equation:

$$46 \quad \bar{c} = \sqrt{\frac{8RT}{\pi MW}} \quad (2)$$

47 in which R is the ideal gas constant (i.e., $8.314 \text{ J mol}^{-1} \text{ K}^{-1}$), T is the experimental
48 temperature ($T=288.15 \text{ K}$ in this study), and MW is the molecular weight.

49

50 **Text-S2 The saturation vapor pressure (C^*)**

51 Based on the method developed by Li et al. (2016) to estimate saturated vapor pressure
52 (C^*) through molecular formulas, this study estimates the C^* of the main gas phase HOMs
53 products in the photooxidation process of isoprene under the influence of NO_x :
54

$$55 \quad \log C^* = (n_c^0 - n_c) b_c - n_0 b_0 - 2 \frac{n_c n_0}{n_c + n_0} b_{co} - n_N b_N - n_S b_S$$

56 where n_c^0 is the number of reference carbon atoms, n_c , n_0 , n_N , n_S are the number of
57 carbon, oxygen, nitrogen, and sulfur atoms, respectively; b_c , b_0 , b_N , b_S are the
58 contribution of each atom to $\log C^*$, respectively, and b_{co} is the carbon-oxygen non-
59 inertness factor.

60 **Text-S3 NO₃ calculation**

61 The NO₃ concentration were calculated to analyze the role of NO₃ in SOA formation. The
 62 calculation methods are as follows:

69 Once the NO₃ radical is produced via R3, it rapidly establishes thermal equilibrium with
 70 N₂O₅ in the presence of NO₂ (reactions (6) and (7)), which can be summarized as:

71 $[N_2O_5] = k_{eq}[NO_2][NO_3], k_{eq} = k_4/k_5$ (9)

72 k_{eq} is calculated by the method given by Yan et al., (2023). Assuming that NO₃ and
 73 N₂O₅ are in a steady-state condition, their total formation rate is roughly the same as the
 74 total loss rate, and much greater than the net change rate, then the steady-state NO₃ mixing
 75 ratios are expressed by Eq. (10)

76 $[NO_3]_{SS} = \frac{k_1[NO_2][O_3]}{k_2[Isop] + K_3[NO] + J_{NO_3} + k_{N_2O_5}k_{eq}[NO_2]}$ (10)

77 With a room temperature, rate constant of $k_1 = 3.2 \times 10^{-17} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$; $k_2 = 6.5$
 78 $\times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$; $k_3 = 2.6 \times 10^{-13} \text{ cm}^3 \text{ molecule}^{-1} \text{ s}^{-1}$; J_{NO_3} is the sum of the
 79 photolysis coefficients of the two photolysis reactions of NO₃, 0.176 s⁻¹ (Brown and Stutz,
 80 2012). The $k_{N_2O_5}$ is the heterogeneous uptake rate of N₂O₅ on the aerosol surface, which
 81 can be calculated by Eq. (11):

82 $k_{N_2O_5} = \frac{1}{4} cS\gamma$ (11)

83 Where C is the mean molecular speed of N_2O_5 , which is 240 m s^{-1} , S is the concentration of
84 total particle surface area, which can be calculated based on the particle number size
85 distribution, and γ is the uptake coefficient of N_2O_5 (Hu et al., 2023).

Table S1. The $\log_{10}C^*$ of low volatile organic products

Molecular formula	$\log_{10}C^*$	VOC type ^a
C ₅ H ₈ N ₂ O ₈	-0.92	LVOC
C ₅ H ₁₀ N ₂ O ₈	-0.92	LVOC
C ₅ H ₈ N ₂ O ₉	-1.67	LVOC
C ₅ H ₁₀ N ₂ O ₉	-1.67	LVOC
C ₅ H ₉ N ₃ O ₁₀	-3.54	LVOC
C ₅ H ₉ N ₃ O ₁₁	-4.30	LVOC
C ₅ H ₁₁ N ₃ O ₁₁	-4.30	LVOC
C ₅ H ₉ N ₃ O ₁₂	-5.06	LVOC
C ₆ H ₁₀ N ₂ O ₁₄	-5.75	ELVOC
C ₁₀ H ₁₇ N ₃ O ₁₄	-8.08	ELVOC
C ₁₀ H ₁₇ N ₃ O ₁₆	-9.57	ULVOC
C ₁₂ H ₂₀ NO ₁₇	-8.71	ULVOC
C ₁₅ H ₂₀ N ₂ O ₁₄	-8.75	ULVOC
C ₁₅ H ₁₇ N ₂ O ₁₇	-10.78	ULVOC

127 ^aVOC type is defined according to the following ranges: ultralow volatility organic compounds (ULVOCs,
128 $\log_{10} C^* < -8.5$), extremely low volatility organic compounds (ELVOCs, $-8.5 < \log_{10} C^* < -4.5$), low volatility
129 organic compounds (LVOCs, $-4.5 < \log_{10} C^* < -0.5$), semivolatile organic compounds (SVOC, $-0.5 < \log_{10} C^* <$
130 2.5), intermediate volatility organic compounds (IVOC, $2.5 < \log_{10} C^* < 6.5$), and volatile organic compounds
131 (VOC, $\log_{10} C^* > 6.5$). (Li et al., 2016)
